the course of half a minute, and each time excepting the last was re-ignited. The depth at which *D* can be safely conducted is a question of importance. The ordinary depth at which the *D*-bell has been employed in harbor works is from 30 to 35 feet, and it has been used in 60 feet at Dover, in England. With the *D*-dress much greater depths have been attained; and it is related that in removing the cargo of the ship "Cape Horn," wrecked off the coast of South America, a diver named Hooper made seven descents to a depth of 201 feet, and at one time remained 42 minutes, supposed to be the greatest *D* feat ever achieved. The practice of *D* obliges the diver to conduct his work under a pressure greater than that of the atmosphere at the surface of the earth. All diving work is done under an abnormal atmospheric pressure, which increases with the depth at which the diver is submerged in water. This pressure, when he is submerged to the depth of 33 feet, is twice that of the normal superficial atmospheric pressure. At greater depths the pressure is proportionately increased, and ultimately becomes so great that life could not be maintained. To descend even to the moderate depth of 30 or 40 feet, which is about the maximum required for ordinary engineering sea-works, demands some practice and nerve on the part of the diver; but when greater depths have to be explored, in raising sunken vessels, for example, the energy and power of endurance of the diver are much more severely taxed. The sensations experienced in a *D*-bell are common, it is believed, to all divers. Very soon after the lips of the bell have touched the surface of the water pain is felt in the ears and above the eyes, which continues with greater or less intensity according to the rate of descent until the bell has attained the bottom. So long as the bell continues there no pain is felt, the only feeling being that of depression due to the depth to which the diver is submerged. As soon as the upward movement commences the pain in the ears and above the eyes returns, and continues till the surface is reached. The motion of the bell is very gradual, sometimes not exceeding 3 feet per minute, but even at that slow rate the head does not accommodate itself to the increase of pressure so as to avoid inconvenience. Aeronauts do not suffer to the same extent in their ascents in balloons, because the alteration of pressure is much more gradual in passing through the atmosphere than through a medium having the density of water. The greatest pressures to which men are subjected in engineering works are experienced in the compressed-air cylinders used in bridge building. Captain Eads, the engineer of the St. Louis Bridge, gives some interesting information, in his reports to the directors of the Illinois and St. Louis Bridge Company, on the effect of working under high pressure on the men. The maximum depth to which the cylinders had to be sunk was 110½ feet below summer water-level, and the greatest pressure under which the men worked was 60 or 51 lbs. on the square inch. When the depth of 60 feet had been reached some of the men were affected by paralysis of the lower limbs, which usually passed off in a day or two. At greater depths the symptoms were more severe. The duration of working in the air chamber was gradually shortened from four hours to one hour. The total number of men employed in working under pressure was 352, of whom 30 were seriously affected and 12 cases proved fatal.

**Djidda.** See JIDDA.

**Djung,** a large superficial measure for land in the Eastern Archipelago, equal to four bahus, or about 284 acres.

**Do.** See DITTO.

**Dock,** an artificial enclosure or basin for the reception of ships.

*Wet D.* are generally constructed with gates to retain the water. Ships are admitted at high water; and the gates being shut, they are kept constantly afloat. "In ports where vessels would be naturally much exposed during rough weather, or where the changes in the tide are very great, the necessity of secure and well-sheltered docks, or artificial basins, in which ships may be safely moored and kept at one level, is especially manifest. In the northern parts of Europe the rise and fall of the tides are so great that every port which has any pretensions to a first-class mercantile harbor is necessarily supplied with one or more wet *D*; at most of the ports of England, and especially at those of Liverpool and London, *D* have been constructed on a truly magnificent scale. In many ports throughout the world — such, for example, as that of New York, where the harbor is naturally protected, and as also in the Mediterranean, where the rise and fall of the tides is so small as not to obstruct the loading and unloading of ships — wet *D*. are not an absolute necessity

to commerce, though there is no doubt that the excellent appendages which are attached to them, such as the wharf-room, the magnificent quays and warehouses, the railway connections, cranes, etc., of the *D.* of Liverpool and London, and, by no means least of all, the excellent police arrangements for effecting order and safety from fire and depredation, would most certainly greatly promote the commercial prosperity of any port." — *Johnson's Encyclopedia*.

*Dry D.* are intended for the building, repairing, or examination of ships. The ships to be examined or repaired are admitted into it at high water; and the water either ebbs out with the receding tide, or is pumped out after the gates are shut. Ships may also be conveniently built in dry *D.*, and floated out by opening the gates; though in all dockyards there are places set apart for this purpose under the name of *slips*. Dry *D.* are of two kinds, — the *stationary dry D.*, generally called *graving D.*, and the *floating D.*

*Graving D.* It requires to be perfectly water-tight, and demands the greatest care in its construction. It is sometimes lined all around with wood, but more generally with masonry, mostly of hewn granite. The expense is very considerable, as the foundation, by means of piles or otherwise, must be well secured, all leakage prevented, and the culvers or drains properly constructed, to let in and carry off the water without its undermining the quays or piers. A *graving D.* may be *single*,

Fig. 138. — GRAVING DOCK.

or made to contain only one ship; or *double*, to contain two ships; but the former is the most common, because more convenient. The entrance is closed by gates, which open sideways, like a lock or fall, upon the bed of the entrance, or by caissons. The vessel is floated into the dock at high water, the gates closed, the sluices opened, and the water allowed to run out, or is pumped out, leaving the dock perfectly dry; the vessel (Fig. 138) being supported on timber struts and shores resting upon the steps already mentioned as forming the sides of the dock. The naval dry *D.* of the U. States are among the most stupendous mechanical enterprises of the country; they are constructed at the navy-yards of New York, Charlestown, Norfolk, etc. By far the most extensive and magnificent of these structures is the granite *graving D.* at Brooklyn; 80,000 tons of stone were used in its construction; the masonry foundations are 400 feet in length and 120 in breadth. The main chamber is 286 feet long, and 30 feet broad on the bottom; 307 feet long, and 98 feet broad at the top within the folding gates; the height of the wall is 36 feet. The work was commenced in 1841, and took 10 years to complete it; the aggregate expenditure was above \$2,100,000.

The naval *graving D.*, at Boston, built of granite, and completed in 1833, is 253 feet in length and 86 feet in width inside the chamber; the turning-gates and the caisson are of timber and composition fastened with copper bolts; the caisson being 60 feet in length, 30 feet in height, and 16 feet in width amidships. The total cost of this *D.* was about \$700,000.

*Floating D.* Of the several varieties of this *D.* we will mention the following: The *Sectional D.*, intended to lift a vessel above the surface of the water, in order that its bottom may be cleaned. It consists of a series of caissons connected with a platform, which is introduced below the vessel, and, the water being pumped from these caissons by means of steam-engines, the vessel is raised by their flotation. The apparatus is towed to any place where it is necessary to apply it. The sectional *D.* in the Philadelphia navy-yard is made in nine separate and independent sections, differing only in their widths. Each section consists of a pontoon or tank, water-tight, 105 feet in length, 30 or 32 feet in width, and 11 feet in depth; two end-frames, and two end-floats. Together, the sections form a floor of over 300 feet in length and 105 feet in width. At each end of each section is an open frame in which is a float connected with the four posts of the framework, which is raised and lowered by machinery, — raised to assist in sinking the main tank to the depth required, or lowered into the water to give it greater buoyancy. — The *Balance D.*, like the preceding, is constructed of timber, and consists of a pontoon bottom with two side walls, possessing sufficient displacement to carry the whole weight of the dock and the vessel to be raised. The side walls are hollow and of considerable width, serving, like the floats in the sectional dock, to preserve its stability in rising and sinking. The outside of these walls is vertical, while the inside is sloping, so as to conform to a certain extent to the shape of the ship. Port-holes are made in the walls for ventilation. The walls also afford the means of shoring up the ship, as in a stone *D.*; on the top are the engine-house, pumps, and working platform. There are sometimes gates at the ends for enclosing the *D.*, which are used only when vessels of great weight are to be lifted. Of this description is the Portsmouth navy-yard *D.*, which is 350 feet in length, 38 feet in depth, and 90 feet in inside width. This *D.*, with the basin and railways, cost \$733,000. The Pensacola *D.*, which is similar, cost \$923,000. There are also balance *D.* at New York, Charleston, Savannah, Mobile, and New Orleans. — The *Hydraulic D.* is an apparatus by which the vessel to be repaired is brought over a platform which is slung between the frames, being suspended by the requisite number of chains, say 20 on each side, which pass over cast-iron pulleys supported on the top of the wooden framework. The lower ends of the chains are fixed to the platform, and the upper ends to a horizontal beam of wood, which is attached by means of a cross-head to the ram of an hydraulic engine. When the ram, therefore, which is placed in a horizontal position, is moved, by the injection of water into the cast-iron cylinder in which it works, the motion is communicated to the horizontal beam, and thence, by the suspending chains, to the platform bearing the vessel, which is thus slowly raised to the surface. The fixtures of the cylinder are embedded in a large mass of masonry, so as to render it quite immovable. There are several racks attached to the apparatus, for supporting the platform, and taking part of the weight off the ram after the

vessel is suspended. When she is ready to be lowered, these racks are unshipped, and the water being permitted to escape through a small aperture provided in the cylinder for that purpose, the vessel slowly descends into the water. The perpendicular *lift* of one of these *D.* in New York Harbor is ten feet. *Summary accounts of the most important foreign D. are given under the names of the ports to which they belong.*

**Docket**, to label. — A memorandum affixed to papers implying their meaning. — A ticket attached to goods specifying their measurement; also what is tied or fastened to a bundle, as a direction where to deliver it. — To strike a docket is a term frequently used in England for entering a declaration of bankruptcy against a person.

**Dock-Master**, in England, a resident officer who has the superintendence of docks.

**Dock-Rent**, charges for storing and warehousing goods in a dock.

**Dock-Warehouses** are bonded warehouses within the docks of London, Liverpool, etc.

**Dock-Yard**, in Great Britain, a private or government yard, near a harbor or roadstead, where naval stores are kept, and ships built and repaired.

**Doctor**, a medical man holding the degree of M. D. — The scraper in a print-machine which cleanses the surplus color from the surface of the engraving cylinder. — Generally a part in a machine for regulating quantity, adjusting, or feeding.

**Doctoring**, a term applied to injuring or adulterating, as *D.* seed, horses, etc. — The operation of removing with a scraper the excess of color from the cylinder in calico-printing.

**Document**, an official or authoritative paper containing instructions or proof for information, and the establishment of facts.

**Document-Bill**, an Indian bill of exchange drawn on London, having as collateral security the bill of lading and policy of insurance on the goods; against a part of the estimated value of these the bill is drawn.

**Doer**, a Scotch name for an attorney, manager, or steward; synonymous with factor.

**Doeskin**, a woollen cloth for trousers. — A name for deer-skin prepared for gloves.

**Doffer**, a comb or revolving card-covered cylinder in a carding-machine, which strips the fleece or sliver of fibre off the main card-wheel after the filaments have passed the series of smaller carding-rollers and the flat cards.

**Dog** [Fr. *chien*; Ger. *Hund*; It. *cane*; Latin, *canis familiaris*], a well-known quadruped, varying greatly in stature, form, color, and the quality of the hair. Its period of gestation is 63 days, and the whelps, which often number 8 or 9, are born blind, and do not see till after the lapse of 10 or 11 days. The growth of the animal is complete at two years; at the expiration of 5 years it is considered old, and the limits of its existence rarely exceed twenty years. No trace of the dog is to be found in a primitive state of nature; and its parent stock is by many supposed to be the jackal or wolf, particularly the last, to which in many respects it has a strong affinity. "The dog exhibits," says Cuvier, "the most singular, the most complete, and the most useful conquest that man has made. The whole species is become our property; each individual is entirely devoted to his master, adopts his manners, distinguishes and defends his property, and remains attached to him even unto death; and all this springs not from mere necessity, not from constraint, but sim-

ply from *reconnaissance* and a true friendship. The swiftness, the strength, and the highly developed power of smelling of the dog, have made him a powerful ally of man against the other animals, and were perhaps necessary to the establishment of society. It is the only animal that has followed man over all the earth." This account, however, applies solely to the animal as it exists in Europe and America. By Mohammedans and Hindoos it is regarded as impure, and neither will touch one without an ablution; they are, therefore, unappropriated, and prowl about the towns and villages, devouring the offal, thus performing the office of scavengers. In China, Cochinchina, the Society Islands, and other places, it is used as food, and puppies are considered a great delicacy.

In machinery this name is applied to any device with a tooth which penetrates, or grips an object and detains it; a hold-fast.

**Doganiera**, a custom-house officer in Italy.

**Dog-Cart**, a sporting carriage with a box for carrying pointers; also a light jaunting-car.

**Dogfish**, a name applied to several species of the smaller sharks. Their body is round and tapering, the snout projects, and the mouth is placed far under. There are two dorsal fins, each of which is armed on its anterior edge with a sharp and slightly curved spine. Their size varies from 30 inches to 5 feet. They are very prolific, the female producing young almost daily for 9 or 10 months in the year. These are not contained in egg cases, as in the ground-sharks, but are produced alive. The common *D. (Acanthius vulgaris)*, is abundant along the New England coasts, and is the special enemy of the fisherman, injuring nets, removing the hooks from his lines, and spoiling his fish for the market by biting pieces out of them as they hang to his lines. They are, however, caught in great numbers for the excellent oil their livers yield. The rough skin of the *D.* is used for polishing wood and other substances.

**Dogger**, a two-masted Dutch fishing-vessel, resembling a ketch, often fitted with a well for fish.

**Dog-Shores**, short pieces of timber fitted to the upper end of the bilgeways on a building-slip, which are knocked away to facilitate the sliding or launching of a vessel.

**Dog-Skin**, gloves, etc., are made of the skin of the dog. *Dog-skin gloves* is the trade-mark, in New York, for a superior kind of sheep-skin gloves.

**Dog-Stones**, rough, shaped, or hewn pieces of stone used to make millstones.

**Dog-Vane**, a small vane on the mast-head to show the direction of the wind.

**Dog-Watch**, a short watch, or spell of duty on shinboard, of only two hours.

**Dogwood**, the wood of *Cornus Florida*, a deciduous American tree. It is hard, compact, heavy, and fine-grained, and is susceptible of a brilliant polish, from which circumstance it may be substituted for numerous purposes to which boxwood is applied. The sap-wood is perfectly white, and the heart-wood is of the color of chocolate. In the U. States it enters into the construction of many articles, both for utility and ornament, such as the handles of light tools, mallets, toys, etc. It is sometimes used by farmers for harrow-teeth, for the hames of horse-collars, and also for shoeing the runners of sleds; but to whatever purpose it is applied, being liable to split, it should never be wrought till it is perfectly seasoned. The shoots, when three or four years old, are found suitable

for the light hoops of small casks, and in the Middle States the cogs of mill-wheels are made of them, and the forked branches are converted into the yokes which are put upon the necks of swine, to prevent them from breaking into enclosed fields. In the parts of the country where it abounds, it serves for excellent fuel. The inner bark of this tree is extremely bitter, and is used as a good substitute for the Peruvian bark. The bark also may be substituted for galls in the manufacture of ink, and from the bark of more fibrous roots the American Indians obtain a scarlet dye. An infusion of the flowers of this tree is also used by them in the cure of intermittents. The fruit is sometimes taken as a tonic, in the form of a spirituous impregnation, and it likewise forms a favorite repast for various species of birds.

**Doley**, a division of the Russian pound, 96 doleys making 1 zolotnick, and 96 zolotnicks 1 Russian pound: 10 Russian pounds are equal to about 9½ English pounds.

**Doll** [Fr. *poupée*; Ger. *Puppe*], a toy of wax, wood, or plaster, made like the image of a child, and used as a plaything. They are chiefly manufactured in Nuremberg, Germany. *Imp. duty*, 35 per cent. Doll's wardrobes and toilet articles are held dutiable as toys: 50 per cent.

**Dollar** [Ger. *Thaler*; Danish, *daler*; from the Anglo-Saxon *dal*, Ger. *Thal*, a valley, the coin being said to have been first struck in the *dale* or valley of Joachim, Bohemia, in 1518], a silver and gold coin and the money unit of the U. States, its value being 100 cents, or the 10th part of an eagle. Its value was originally the same as that of the old Spanish *D.* or *piastre*, but is now somewhat below. The origin of the *D.*-mark, or sign \$, is not known. It is asserted that it is a contraction for U. S.; and by placing the letter S over the letter U, a very fair \$ mark is produced. It has also been asserted that the columns or pillars on the old pillar *D.*, which were connected by a scroll, bear such a resemblance to the \$ mark as to account for its origin. But the more probable opinion is that it is merely a modification of the figure 8, intended for 8 reals or "a piece of 8." — It was coined in silver only until 1849, when the coinage of gold *D.* was authorized. By act of Feb. 28, 1878, the silver *D.* is legal tender for all debts, public and private, except when otherwise expressly stipulated in the contract. The half-*D.*, quarter-*D.*, twenty-cent piece, and dime are legal tender for twenty *D.* only. The market value of the silver in the *D.*, which was 93½ cents in gold coin when the act of Feb. 28, 1878, was passed, is now only about 86 cents in gold coin.

*The authority for coining D. and subdivisions, changes in weight and fineness, and total amount coined to close of fiscal year ended June 30, 1878, are as follows:—*

*Gold D.*, authorized to be coined, act of March 3, 1849; weight, 26.8 grains; fineness, 900; total amount coined, \$19,346,158.

*Gold three-D. piece*, authorized to be coined, act of Feb. 21, 1854; weight, 77.4 grains; fineness, 900; total amount coined, \$1,708,932.

*Silver D.*, authorized to be coined, act of April 2, 1792; weight, 416 grains; fineness, 892.4. By act of Jan. 18, 1837, weight was changed to 412½ grains, and fineness to 900. Coinage discontinued, act of Feb. 12, 1873; total amount coined, \$8,045,833. Coinage reauthorized, act of Feb. 28, 1878; amount coined since the passage of this act (4 months), \$8,573,500.

*Trade D. (silver)*, authorized to be coined, act of Feb. 12, 1873; weight, 423 grains; fineness, 900; total amount coined, \$35,959,200.

*Half-D.*, authorized to be coined, act of April 2, 1792; weight, 208 grains; fineness, 892.4. By act of Jan. 18, 1837, weight changed to 206½ grains, and fineness to 900. Weight changed to 192 grains by act of Feb. 21, 1853; and to 12½ grains, or 192.5 grains, by act of Feb. 12, 1873. Total amount coined, \$122,744,795.50.

*Quarter-D.*, authorized to be coined, act of April 2, 1792; weight, 104 grains; fineness, 892.4. By act of Jan. 18, 1837, weight changed to 103½ grains, and fineness to 900. Weight changed to 96 grains by act of Feb. 21, 1853, and to 61 grains, or 96.45 grains, by act of Feb. 12, 1873. Total amount coined, \$38,477,149.

*Twenty-cent piece*, authorized to be coined, act of March 3, 1855; weight, 5 grains, or 77.16 grains; fineness, 900. Coinage discontinued, act of May 2, 1878; total amount coined, \$271,000.

For further information, see **MONEY**. See also **COPPER COINS**, **DIME**, **EAGLE**, **GOLD**, **MINT**, **SILVER**, **TRADE-DOLLAR**. For foreign dollar coins, see the names of countries to which they belong.

**Doll's-Eyes**, blue and black glass beads, which are extensively made in Austria and in Birmingham, England, and sold to doll manufacturers.

**Dolly**, in mining parlance, a perforated board, placed over a tub containing ore to be washed, and which, being worked by a winch-handle, gives a circular motion to the ore. — A machine for washing clothes.

**Dolomite**, a variety of magnesian limestone, admirably adapted for mortar, as it absorbs less carbonic acid than the common limestone; a white variety of dolomite was used by ancient sculptors.

**Dolphin**, a spar or buoy, with a large ring in it secured to an anchor, to which vessels may bind their cables. — In hydraulics, the induction-pipe of a water-main, and its cover, placed at the source of supply.

**Domba Oil**, a fragrant fixed oil obtained in India from the seeds of the Alexandrian laurel (*Calophyllum inophyllum*). It is used for burning and for medicinal purposes, being considered a cure for the itch.

**Domesticate**, to tame, to make familiar.

**Domestic Goods**, a general term for all goods and produce of home growth or manufacture.

**Domestics**, American cotton goods, such as sheetings, shirtings, etc. — Household servants or hired laborers.

**Domestic Wines**, wine made from native grapes. See **WINE**.

**Domett**, a mixed cotton and woollen fabric used for baize; also a kind of white flannel made in Germany.

**Domicile**, a dwelling; a place of permanent residence.

**Domiciled Bill**, a bill not made payable at the residence or place of business of the acceptor, but directed for payment by the acceptor at the time of his acceptance.

**Dominica**, a British West India island, the largest in the Leeward group of the Lesser Antilles, lying between the French islands of Martinique and Guadeloupe, 24 m. N. of the former and about the same distance S. of the latter, at the intersection of lat. 15° 30' N., lon. 61° 30' W. It has a length of 29 m., with a maximum breadth of 16 m.; area, 291 sq. m. The longer axis is formed by a chain of mountains which attain in some parts a height of upwards of 5,000 feet, and give the whole island a strongly marked profile and great irregularity of surface. The results and symptoms of volcanic activity are abundant in the shape of solfataras, emissions of subterranean vapors, and hot springs; and in the S. part of the island there exists a boiling lake of unascertained depth, in which the water is frequently projected 3 feet or more above the surface by the force of the ebullition. The coasts of the island are not much indented, and the only anchorages of importance are Prince Rupert's Bay and Roseau, both on the N. W. side. The cap. is *Roseau*, or Charlotteville, a fortified port near the S. end of the island; pop. 5,000. The total tonnage of the ships that annually enter

and clear amounts to about 18,000 tons, the four fifths of which belong to Great Britain. The annual imports are valued at about \$300,000, and the exports at \$350,000. The principal products are sugar, molasses, rum, coffee, cocoa, and oranges. Pop. 27,178.

**Dominican Republic.** See SAN DOMINGO.

**Domino**, a long, loose cloak of black silk, etc., with a hood removable at will, used as a general disguise at masquerades. — A semi-mask worn by ladies to conceal the upper part of the face at *bals masqués*, etc. — A game played with 28 flat, oblong pieces of ivory or bone, each of which, called a *D.*, is divided by a line into two parts, bearing numbers marked by points. *Imp.* duty, 35 per cent.

**Donation**, a gift or bequest.

**Donkey**, an ass for the saddle or for draught.

**Donkey-Engine**, an auxiliary engine, used principally for pumping water into boilers, lifting heavy weights, etc.

**Donkey-Pump**, a steam-pump for feeding steam-engine boilers. It is used as a substitute for

the feed-pump portion of the large engine. It is also used in breweries, distilleries, etc.

**Doooco**, an excellent fruit of Java, the *Lausium domesticum*.

**Doom-Palm**, the *Hyphæne Thebaica* (Fig. 139), which is highly valued in Egypt for its fruit. The wood is used for various domestic purposes; the rind of the fruit, which has the taste of gingerbread, is eaten, and the kernel turned into beads for rosaries.

**Doopada Resin**, a resin obtained in considerable quantities in the East Indies, from the *Vateria Indica*, which is used as a fragrant incense in the temples, makes an ex-

Fig. 139. — DOOM-PALM.

cellent varnish, and is sometimes called East Indian copal, or gum Piney.

**Door** [Fr. *porte*; Ger. *Thüre*], the movable panel by which the doorway or entrance to any building, apartment, closet, or court is closed. The most common kind of *D.* consists of boards joined together, and nailed to transverse slips of wood. Such as these are called *ledge-doors*. They are hung on staples, and fastened by a latch; they are principally used for workshops, out-houses, offices, and walled gardens. The ordinary house-door is fastened to one side of the doorway by hinges (see *HINGES*), on which it swings. It is secured by a box-lock fixed to the inner side, or by a mortise-lock, which is buried in the lock-rail, and worked by handles projecting on either side. These *D.* are made of panels fixed in a solid framework, and finished by mouldings of different kinds, which surround the panel. The horizontal pieces of the frame are called *rails*, and the vertical pieces *styles*. *D.* are technically described by the num-

ber of panels they contain, and by the kind of moulding with which they are finished. When they move on hinges, like the ordinary doors of apartments, they are termed *swing-doors*. Large double-*D.*, used to separate any long room, are called *folding-doors*. A *jib-door* is a *D.* in a wall, which cannot well be detected when closed. A *rolling* or *sliding door* is one which travels on rollers, or in a groove, parallel and close to the wall in which is the aperture that it is intended to close. A smaller *D.*, which closes an opening cut in the entrance-door of a courtyard or large building, is called a *wicket-door*. A *trap-door* is a *D.* cut in the floor to give access to cellars, or open parts under the roof of a house. *D.* of large public buildings are sometimes made of brass, or even of stone or marble.

**Door-Fastener**, the catch for a door.

**Door Frame** or **Case**, the case in which a door opens and shuts, consisting of two upright pieces and a horizontal one, connected together by mortises and tenons.

**Door-Knob**, a handle for turning the lock of a door.

**Door-Knocker**, a hand-rapper for a street door or outer door on a stairway.

**Door-Latch**, an iron bolt or catch for fastening a door.

**Door-Mat**, a coarse rough mat placed at doorways, or entrances from the street, to clean the shoes on.

**Door-Plate**, a metallic engraved name-plate.

**Door-Spring**, a spring attached to or bearing against a door, so as automatically to close it.

**Door-Stop**, a knob or block on a skirting-board or floor, against which the door shuts, the object of which is to prevent the door-knob from bruising the wall.

**Doputta**, a wrapper or garment of cotton, worn by the natives of India.

**Doremal**, a kind of flowered muslin made in Spain.

**Dornick**, or **Dornock**, a stout figured linen made for table-cloths; so named from Tournay (Flemish *doornic*), a town of Belgium, or from Dornock, a town of Scotland.

**Dorsour**, cloth for hanging on the walls of a hall or chapel in Scotland.

**Dose**, a variable quantity of medicine to be swallowed. — Also the proportion of anything liquid applied in manufacture.

**Dot**, a small point or spot, made with a pen or other sharp-pointed instrument.

**Dotchin**, a Chinese portable balance for weighing coins and merchandise, made somewhat after the plan of the steelyard.

**Douanier**, a French custom-house officer.

**Double-acting Engine.** See STEAM-ENGINE.

**Double-acting Pump**, a pump (Fig. 140) which lifts and forces water at the same time, by

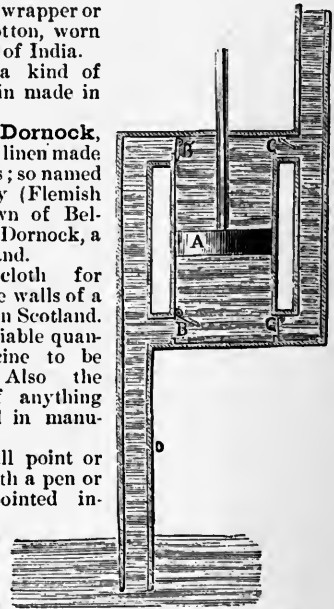

Fig. 140. — DOUBLE-ACTING PUMP.

means of a solid piston, A, having induction and eduction valves, B, C, in the upper and lower chambers.

**Double-cylinder Engine**, a marine engine with two cylinders placed at right angles to the crank-shaft, and at a small distance apart, to give space for the vibration of the rod connecting the crank to the long end of a shaped cross-head, which slides in grooves between the cylinders; the upper ends of the cross-head are connected to the piston-rods.

**Double d'Or** is a kind of French gilt jewelry. The metal used is composed of plate copper with a layer of gold upon it; the thickness of the two being as 11 to 1. The adhesion is produced by means of soldering. The metal is reduced to the required thickness by flattening and drawing, and great care is necessary throughout to prevent the gold from separating from the copper. Many of the articles are made by stamping with steel dies, and the plan seems to offer much scope for taste in design.

**Double-Eagle**. See EAGLE.

**Double-Entry**. See BOOK-KEEPING.

**Double-Elephant**, a size of drawing or flat writing-paper measuring  $26 \times 40$  inches.

**Double-milled Cloths** are woollen cloths which are fullered or shrunk by being put through the fulling-machine twice.

**Double-Pica**. See PICA.

**Double-Royal**, a size of printing-paper  $26 \times 40$  inches.

**Doublet**, a counterfeit gem made with a colorless front and a colored back, cemented together by clear mastic on the line of the girdle. — A kind of netted silk. — A waistcoat or jacket.

**Doubloon**, a Spanish and South American gold coin, which weighs 417.70 troy grains, of which 365.49 grains are pure. Mint value, \$15.00.

**Douceur**, a gift, or bonus.

**Douche**, a surgical instrument for injecting a liquid into a cavity, usually known by the name of the part to which they are applicable.

**Dough**, flour or meal which has been kneaded with water, and leavened with yeast ready for baking.

**Dover**. See GREAT BRITAIN.

**Dovetail**, a joint used by carpenters and joiners in connecting two pieces of wood, by letting one into the other, in the form of the expanded tail of a dove. It is the strongest method of joining masses, because the tenon or piece of wood widens as it extends, so that it cannot be drawn out, the tongue being larger than the cavity through which it would have to be drawn.

**Dovetailing**. Several examples of dovetailing are given in Fig. 141. The parts which fit into each other are known by different names; the projecting piece, represented in Fig. 1, is called the pin of the dovetail; and the aperture into which it is fitted, as shown in Fig. 2, is called the socket. Now, the strength of a dovetail depends upon so proportioning the pin and the socket as to enable them to support, rather than destroy, each other. Let A B C D, Fig. 1, be a scantling, which is required to be joined to another, by means of a single dovetail. The strength of the joint depends on the form of the dovetail, as well as on the proportion it bears to the parts cut away. We shall endeavor to lay down the principle on which the greatest strength may be secured. Having squared the end of the scantling, and gauged it to the required thickness, A I K L M, divide I M into three equal parts, at K and L. Let K L be the small end of the dovetail, and make the an-

gles I K G and M L H equal to about 75 and 80 degrees respectively; and make G E and H F parallel to A N and B O. Then cut away the parts, A I K G E N and B M L H F O, and having formed the socket to correspond, by marking the form of the dovetail on the top of the piece, A B C D, Fig. 2, and cutting away accordingly, the pieces may be fitted together, as shown in Fig. 3. It may be here observed, that the bevel of the dovetail, that is, the angle I K G, Fig. 1, may be either more or less than has been mentioned, according to the texture of the wood. Hard, close-grained woods, not apt to rive or split, will admit of a greater bevel than those which are soft, or subject to split; thus, the bevel of a dovetail in deal must be less than in hard oak, or in mahogany. It is a great fault to make a dovetail too bevelling, for, instead of adding to the strength of the joint, as some persons suppose, it weakens it: for, provided the bevel is sufficient to prevent the possibility of pulling the pieces apart, the less the bevel that is given the better. It must have been observed, that there is a great difference between the dovetail made by the cabinet-maker and by the joiner; the former has very little bevel the latter very much; the former looks neat, and is at the same time strong, while the latter, appearing to aim at strength, looks clumsy, and is at the same time much the weaker of the two. Fig. 4 represents the dovetail in common use for drawer-fronts. When it is required to hide the appearance of the joint in front, the board A B C D is cut with the pin, and A E F B with the socket. The pins in this sort of dovetail are in general from about three quarters of an inch to an inch apart, according to the size of the pieces to be joined. Fig. 5 represents the pin part of a lap dovetail, which, when put together, shows only a joint, as if the pieces were rebated together. This kind of dovetail is very useful for many purposes where neatness is required, such as in making boxes.

Fig. 141. — DOVETAILING.

**Dovetty**, a wrapping-cloth or garment of silk, or some mixed fabric, worn by rich natives in Madras.

**Dow**, an Arabian coasting vessel, with one mast, carrying a lateen sail.

**Dowel**, a pin of wood or iron used at the edges of boards in laying floors, to avoid the appearance of nails on the surface.

**Dowelling**, a method of corking, or joining, by letting pieces into the solid, or uniting two pieces of timber together by tenons.

**Dowlas**, a coarse linen fabric, stout and strong, used for shirting.

**Down** [Fr. *duvet*; Ger. *Dunen*, *Flaumfedern*; It. *penna matta*, *piumini*; Sp. *flojel*, *plumazo*], the fine feathers from the breasts of several birds, particularly those of the duck kind. That of the eider-duck is the most valuable. These birds pluck it from their breasts, and line their nests with it. It is so very elastic, that a quantity of it weighing only  $\frac{1}{4}$  of an ounce more than fills the crown of the largest hat. That found in the nest is most

valued, and termed *live down*; it is much more elastic than that plucked from the dead bird, which is comparatively little esteemed. The eider-duck is found on the western islands of Scotland, but the down is principally imported from Norway and Iceland. It is extensively used in Europe for bed covering, and is worth about 75 cents per lb. *Imp. free.*

**Down-Cast**, the ventilating-shaft of a mine, down which air passes to the workings.

**Down-Haul**, a rope attached to a staysail, or jib, to pull it down by.

**Down-Tree**, the *Ochroma lagopus* of the West Indies, the seed-pods of which produce a kind of silk cotton used for stuffing pillows, etc.

**Doyley**, or **Doily**, a small fancy napkin or plate-cover, of different materials.

**Dozen**, twelve in number.

**Drab**, a woollen cloth of a dun color, generally woven thick and double milled, for great-coats. — A kind of wooden box used in salt-works for holding the salt when taken out of the boiling-pans.

**Drabbets**, a coarse linen fabric, or duck.

**Drachm**, **Dram**, the name of two English weights. In apothecaries' weight, the eighth part of the troy ounce, or 60 troy grains; and the one sixteenth part of the avoirdupois ounce, or  $27\frac{1}{2}$  troy grains. The latter, however, is seldom used. In medicine, the *D.* weight is expressed in prescriptions by the symbol  $\mathfrak{z}$ , equal to 3 scruples; or, in liquids, the eighth part of an ounce measure. — The principal silver coin and money of account in Greece, worth 17 cents.

**Draft**, an inland or domestic bill of exchange; a check or order for money on a banker or other person. — A deduction allowed from the gross weight of goods. — The quantity of grain or merchandise weighed at one time. — A plan of a building. — A rough copy of any writing. — The draft of a ship is the number of feet she sinks in the water, or the depth of water necessary to float it.

**Drafts**, or **Draughts**, turned pieces of wood or bone, etc., for playing the game of drafts on a checker-board.

**Drag**, a dredging-machine. — An instrument with hooks, to catch hold of things under water and bring them to the surface. — A low cart on which a log is dogged in a veneer saw-mill. — A skid, or chain, to lock the wheel of a vehicle in descending hills; a brake. — An agricultural implement (Fig. 142) with hooking tines to haul manure

Fig. 142. — MANURE-DRAG.

along the surface. — In marine engineering, the difference between the propulsive powers of the various floats of a paddle-wheel, or blades of a screw-propeller. — In masonry, a steel instrument for completing the dressing of soft stone without grit. — The bottom part of a mould. — A floating

anchor, usually a frame of spars and sails, to keep a ship's head to the wind, and lessen the speed of drifting.

**Dragon-Cane**, a thick kind of rattan imported from China, with long internodes and a hard bark, less flexible than the common rattans, but strong, springy, and much valued. A variety with soft bark is called Manilla dragon-cane, and is believed to be the stem of *Calamus draco*.

**Dragon's Blood**, a resinous astringent extract, of a deep red color, obtained from the fleshy fruits of the *Calamus draco*, a plant of Sumatra and the Malay islands. It is chiefly used as a coloring ingredient for spirit and turpentine varnishes and paints, for staining marble, preparing gold lacker, dentifrices, etc. *Imp. free.*

**Drag-Rope**, a rope attached to a ship, canal-boat, or any object for traction.

**Drain**, to draw off or filter; also a sink or water-channel.

**Drainage**, the systematic process employed for carrying off water from land.

**Drain-Tile**. See **TILE**.

**Drain-Traps**, contrivances for preventing the escape of foul air from drains, but allowing the passage of water into them.

**Drake**, the male of the duck.

**Dram**, a small quantity of an alcoholic draught.

**Drama**, a play, whether comic or tragic.

**Dramatist**, a writer of plays.

**Drain-Bottle**, pocket glass bottle for travellers and others, cased with leather or straw.

**Drap**, the French name for cloth of any kind.

**Drap d'été**, a thin worsted fabric for gentlemen's summer clothing.

**Drape**, to cover with cloth or drapery; as, to drape an apartment.

**Draper**, in England, a dealer in cloth.

**Drapery**, an artist's term for the clothing or dress of a figure or statue; by upholsters it is applied to bed and window curtains, tapestry, and hangings of any kind. — Also a general name in England for the woollen and linen fabrics retailed by drapers. In its primary sense, from the French word "drap," it means woollen goods only, but has been extended to cotton prints and linens. Thus, a dealer in calicoes is called a linen-draper, to distinguish him from what is called a draper, but the goods of both are alike denominated "drapery."

**Drapiere**, a French clothier, or cloth manufacturer.

**Draping**, the ancient name for making cloth, whence the word "draper."

**Draippiere**, an Italian weaver.

**Drappe**, a name for silk stuffs and cloth in Italy.

**Drastics**, medicines which are rapid and powerful in their operations.

**Draught**, a liquid form of medicine intended to be taken at once, or at a draught. — See **DRAFT**.

**Draughts**. See **DRAFTS**.

**Draughtsman**, **Draftsman**, one who draws out plans and designs.

**Draw**, to haul or pull along. — To sketch or design. — To raise water from a well, or liquors by a trap.

**Drawback**, a term used in commerce to signify the remitting or paying back of the duties previously paid on a commodity on its being exported. A *D.* is a device resorted to for enabling a commodity affected by taxes to be exported and sold in the foreign market on the same terms as if it had not been taxed at all. It differs in this from a bounty, — that the latter enables a commodity

to be sold abroad for less than its natural cost, whereas a *D.* enables it to be sold exactly at its natural cost. Were it not for the system of *D.*, it would be impossible, unless when a country enjoyed some very peculiar facilities of production, to export any commodity that was more heavily taxed at home than abroad; but the *D.* obviates this difficulty, and enables merchants to export commodities loaded at home with heavy duties, and to sell them in the foreign market on the same terms as those fetched from countries where they are not taxed. — Most foreign articles imported into this country may be warehoused for subsequent exportation. In this case they pay no duties on being imported, and, of course, get no *D.* on their subsequent exportation. The laws relating to *D.* (*Revised Statutes of the U. States, Edition 1878*) are as follows: —

**Customs: —** Sect. 2977. Merchandise upon which duties have been paid may remain in warehouse in custody of the officers of the customs at the expense and risks of the owners of such merchandise, and if exported directly from such custody to a foreign country within 3 years, shall be entitled to return duties. But proper evidence of such merchandise having been landed abroad shall be furnished to the collector by the importer, and one per cent of the duties shall be retained by the government. — Sect. 2978. No merchandise subject to duty shall be entered for *D.*, or exported for *D.* after it is withdrawn from the custody of the officers (except as provided in Sect. 3025). — Sect. 3015. A *D.* of duties shall be allowed and paid on all merchandise imported into the U. States, in respect to all such merchandise as shall be exported to any foreign port other than the dominions of any foreign state immediately adjoining to the U. States, either from the district of original importation, or from certain other districts; and all duties, *D.* and allowances which shall be payable, or allowable, on any specific quantity of merchandise, shall be deemed to apply in proportion to any greater or less quantity, except as herein otherwise provided. (See §§ 3036, 2977, 2978). — Sect. 3016. No merchandise imported shall be entitled to a *D.* of the duties paid, unless the duties so paid shall amount to \$50 at least; nor unless they shall be exported in the original casks, cases, chests, boxes, trunks, or other packages, in which they were imported, without diminution or change of the articles which were therein contained, at the time of exportation, in quantity, quality, or value, necessary or unavoidable wastage or damage only excepted. — Sect. 3017. No *D.* of the duties shall be allowed on merchandise entitled to debenture under existing laws, unless such merchandise shall be exported from the U. States within 3 years from the date of the importation of the same. One per cent on the amount of all *D.* allowed shall be retained for the use of the U. States by the collectors paying such drawbacks, respectively. — Sect. 3018. All drugs, medicines, and chemical preparations entered for exportation and deposited in warehouse or public store, may be exported by the owner thereof in the original package, or otherwise, subject to such regulations as shall be prescribed by the Sec. of the Treasury. — Sect. 3019. There shall be allowed on all articles wholly manuf. of materials imported, on which duties have been paid when exported, a *D.* equal in amount to the duty paid on such materials, and no more, to be ascertained under such regulations as shall be prescribed by the Secretary of the Treasury. Ten per cent on the amount of all *D.* so allowed shall, however, be retained for the use of the U. States by the collectors paying such drawbacks respectively. — Sect. 3020. Where fire-arms, scales, balances, shovels, spades, axes, hatchets, hammers, ploughs, cultivators, mowing-machines, and reapers, manuf. with stocks or handles made of wood grown in the U. States, are exported for benefit of *D.* under the preceding section, such articles shall be entitled to such *D.* in all cases when the imported material exceeds one half of the value of the material used. — Sect. 3021. Railroad-iron, partially or wholly worn, may be imported into the U. States without payment of duty, under bond to be withdrawn and exported after such railroad-iron shall have been repaired or remanufactured. The Sec. of the Treasury is hereby authorized and directed to prescribe such rules and regulations as may be necessary to protect the revenue against fraud, and secure the identity, character, and weight of all such importations when again withdrawn and exported, restricting and limiting the export and withdrawal to the same port of entry where imported, and also limiting all bonds to a period of time of not more than six months from the date of the importation. — Sect. 3022. Imported salt in bond may be used in curing fish, taken by vessels licensed to engage in the fisheries, under such regulations as the Sec. of the Treasury shall prescribe; and upon proof that the salt has been used in curing fish, the duties on the same shall be remitted. — Sect. 3023. Upon all merchandise gaugeable by law, hereafter exported, upon which *D.* or return duty is allowed, and upon all merchandise gaugeable by

law, withdrawn from bonded warehouses for export, there shall be collected by the collectors of the several ports ten cents per cask. — Sect. 3024. Upon all weighable articles hereafter exported, upon which a *D.* or return duty is allowed, and upon all weighable merchandise withdrawn from bonded warehouses for export, there shall be collected by the collectors of the several ports 3 cents per 100 lbs., to be determined by the returns of the weighers. — Sect. 3025. No return of the duties shall be allowed on the export of any merchandise after it has been removed from the custody and control of the government, except in the cases provided in sections 3019, 3020, 3022, and 3026. (See § 3036). — Sect. 3026. There shall be a *D.* on foreign saltpetre, manufactured into gunpowder in the United States and exported therefrom, equal in amount to the duty paid on the foreign saltpetre from which it shall be manuf. to be ascertained under such regulations as shall be prescribed by the Sec. of the Treasury, and no more. The word "saltpetre" as used in this section shall be construed to mean the element of nitre, so used, whether it be the nitrate of potash or the nitrate of soda. Ten per cent on the amount of *D.* so allowed shall, however, be retained for the use of the U. States by the collectors paying such *D.* respectively. — Sect. 3027. No part of the additional or discriminating duty imposed by law on merchandise on account of its importation in foreign vessels shall be allowed to be *D.*, but the whole shall be retained. — Sect. 3028. Where articles are imported in bulk they shall be exported in the packages, if any, in which they were landed; for which purpose the officer delivering the same shall return the packages they may be put into, if any, with their marks and numbers, and they shall not be entitled to *D.*, unless exported in such packages, which shall be deemed the packages of original importation, nor unless they fully agree with the return made by the officer. — Sect. 3029. It shall be lawful for the exporter of any liquors in casks, or any unrefined sugars, to fill up the casks or packages out of other casks or packages included in the same original importation, or into new casks or packages corresponding therewith, to be marked and numbered as the original casks or packages, in case the original casks or packages shall, in the opinion of the officer appointed to examine the same, be so injured as to be rendered unfit for exportation, and in no other case. The filling up or change of package must, however, be done under the inspection of a proper officer, appointed for that purpose by the collector and naval officer, where any, of the port from which such liquors or unrefined sugars are intended to be exported; and the *D.* on articles so filled up, or of which the packages have been changed, shall not be allowed without such inspection. — Sect. 3030. When the owner, importer, consignee, or agent, of any merchandise entitled to debenture, may wish to transfer the same into packages, other than those in which the merchandise was originally imported, the collector of the port where the same may be shall permit the transfer to be made, if necessary for the safety or preservation thereof. — Sect. 3032. Every importer, owner, consignee, agent, or exporter, who shall enter merchandise for importation, or for exportation, or transportation from one port to another, with the right of *D.*, shall deposit with the collector the original invoice of such merchandise. If not before deposited with the collector, and in that case an authenticated copy thereof, to be filed and preserved by him in the archives of the custom-house, which shall be signed by such importer, owner, consignee, agent, or exporter, and the oath to be made on the entry of such merchandise shall be annexed thereto. — Sect. 3036. All merchandise imported into the U. States, the duties on which have been paid, or secured to be paid, may be transported by land, or partly by land and partly by water, or coastwise, from the district into which it was imported to any port of entry and exported from such port of entry with the benefit of *D.* — Sect. 3038. All debentures shall be issued and made payable to the original importer of the merchandise, entered for exportation, whenever the same shall be requested, in writing, by the exporter, and not otherwise. In respect to any merchandise, on which the duties shall have been paid prior to an entry for exportation, the debenture for the amount of the *D.* of such duties shall be made payable in fifteen days, to be computed from the time of signing the bond, to be given as hereinafter directed. — Sect. 3039. Whenever payment of any debenture is refused by the collector of the district where it was granted, for a longer time than three days, after the same shall have become payable, such refusal to be proved in the same manner as the non-payment of a bill of exchange, the possessor or assignee of such debenture may bring suit thereupon against the person to whom it was originally granted or against any indorser thereof. — Sect. 3040. Debentures shall be assignable by delivery and indorsement of the parties who may receive the same. — Sect. 3041. Where any merchandise is exported from any other district than the one into which it was originally imported, the collector of such district, together with the naval officer thereof, where there is one, shall grant to the exporter a certificate, expressing that such merchandise was exported from such district, with the marks, numbers, and descriptions of the packages and their contents, the names of the master and vessel in which and the port to which it was exported, and by whom, and the names of the vessel and master in which it was brought, and by whom shipped at the district from whence it came, and

the amount of the drawback to which it is entitled. Such certificate shall entitle the possessor thereof to receive from the collector of the district with whom the duties on the merchandise were paid, a debenture or debentures, for the amount of the *D.* expressed in the certificate, payable at the same time, and in like manner as is herein directed for debentures on merchandise exported from the port of original importation.

— Sect. 3042. The collector may refuse to grant such debenture, in case it shall appear to him that any error has arisen, or any fraud has been committed; and in case of such refusal, if the debenture claimed shall exceed \$100, it shall be the duty of the collector to represent the case to the Sec. of the Treasury, who shall determine whether such debenture shall be granted or not. In no case, moreover, of an exportation of goods shall a *D.* be paid, until the duties on the importation thereof shall have been first received — Sect. 3043. Before the receipt of any debenture, in case of exportation from the district of original importation, and in case of exportation from any other district before the receipt of any such certificate, as is hereinbefore required to be granted, the person applying for such debenture or certificate shall, previous to such receipt, and before the clearance of the vessel in which the merchandise was laden for exportation, give bond, with one or more sureties, to the satisfaction of the collector, who is to grant such debenture or certificate, as the case may be, in a sum equal to double the amount of the sum for which such debenture or certificate is granted, conditioned that such merchandise, or any part thereof, shall not be reloaded in any port within the limits of the U. States, and that the exporter shall produce, within the time herein limited, the proofs and certificates required of such merchandise having been delivered without such limits. — Sect. 3044. All bonds which may be given for any merchandise exported from the U. States, and on which any *D.* of duties or allowance shall be payable, in virtue of such exportation, shall and may be discharged, and not otherwise, by producing within one year from the date thereof, if the exportation be made to any port of Europe or America, or within two years, if made to any part of Asia or Africa, a certificate under the hand of the consignee at the foreign port to whom the merchandise shall have been addressed, therein particularly setting forth and describing the articles so exported, their marks, numbers, description of packages, the number thereof, and their actual contents, and declaring that the same have been received by them from on board the vessel, specifying the names of the master and vessel from which they were so received; and where such merchandise is not consigned or addressed to any particular person at the foreign port to which the vessel is destined, or may arrive, but where the master, or other person on board such vessel may be the consignee of such merchandise, a certificate from the person to whom such merchandise may be sold or delivered, by such master or other person, shall be produced to the same effect as that required if the person receiving the same were originally intended to be the consignee thereof. — Sect. 3045. In addition to such certificate, it shall be necessary to produce a certificate under the hand and seal of the consul or agent of the U. States, residing at the place, declaring either that the facts stated in the certificate of such consignee, or other person, are to his knowledge true, or that such certificate is deserving of full faith and credit; which certificates of the consignee, or other person, and consul or agent, shall, in all cases, as respects the landing or delivery of the merchandise, be confirmed by the oath of the master and mate, if living, or, in case of their death, by the oath of the two principal surviving officers of the vessel in which the exportation shall be made. Where there is no consul or agent of the U. States residing at the place of delivery, the certificate of the consignee, or other person hereinbefore required, shall be confirmed by the certificate of two reputable American merchants residing at the place, or if there are no such American merchants, then by the certificate of two reputable foreign merchants, testifying that the several facts stated in such consignee or other person's certificate are, to their knowledge, just and true, or that such certificate is, in their opinion, worthy of full faith and credit; and such certificate shall also be supported by the oath of the master and mate, or other principal officers of the vessel, in manner as before prescribed. The oath of the master and mate, or other principal officers, shall, in all cases, when taken at a foreign port, be taken and subscribed before the consul or agent of the U. States residing at such foreign port, if any such consul or agent reside thereat.

Sect. 3047. In case of loss by sea, or by capture or other unavoidable accident, or when, from the nature of the trade, the proofs and certificates before required are not, and cannot be procured, the exporter shall be allowed to adduce to the collector of the port of exportation such other proofs as they may have, and as the nature of the case will admit; which proofs shall, with a statement of all the circumstances attending the transaction within the knowledge of such collector, be transmitted to the Sec. of the Treasury, who shall have power to allow a further reasonable time for obtaining such proofs; or if he be satisfied with the truth and validity of the proofs adduced, to direct the bond of such exporter to be cancelled. If the amount of such bond shall not exceed the penal sum of \$200, the collector, with the naval officer, when there is one,

and alone, where there is none, may, pursuant to such rules as shall be prescribed by the Sec. of the Treasury, admit such proof as may be adduced; and if they deem the same satisfactory, cancel such bond accordingly.

Sect. 3049. If any merchandise entered for exportation, with intent to *D.* the duties, or to obtain any allowance given by law on the exportation thereof, shall be landed within any port within the limits of the U. States, all such merchandise shall be subject to seizure and forfeiture, together with the vessel from which such merchandise shall be landed, and the vessels or boats used in landing the same; and all persons concerned therein shall, upon indictment and conviction thereof, suffer imprisonment for a term not exceeding six months — Sect. 3050. If any merchandise, of which entry shall have been made in the office of a collector, for the benefit of *D.* or bounty upon exportation, shall be entered by a false denomination, or erroneously as to the time when and the vessel in which it was imported, or shall be found to disagree with the packages, quantities, or qualities, as they were at the time of original importation, except such disagreement as may have been occasioned by necessary or unavoidable wastage or damage only, and except also in cases where permission shall have been obtained according to law to alter or change the quantities or packages thereof, all such merchandise, or the value thereof to be recovered of the owner or person making such entry, shall be forfeited, and the person making such false entry shall also forfeit a sum equal to the value of the articles mentioned or described in such entry. — Sect. 3051. No forfeiture shall be incurred under the preceding section if it shall be made to appear to the satisfaction of the collector, or of the court in which a prosecution for the forfeiture shall be had, that such false denomination, error, or disagreement happened by mistake or accident, and not from any intention to defraud the revenue. — Sect. 3053. Any merchandise imported from the British N. American provinces adjoining the U. States, which shall have been duly entered and the duties thereon paid or secured according to law at either of the ports of entry in the collection-districts situated on the N., N. E., and N. W. frontiers of the U. States, may be transported by land or by water, or partly by land and partly by water, to any port or ports from which merchandise may be exported for benefit of *D.*, and be thence exported with such privilege to any foreign country. The laws relating to the transportation of merchandise entitled to *D.*, and the due exportation and proof of landing thereof, and all regulations which the Sec. of the Treasury may prescribe for the security of the revenue, must, however, be complied with. — Sect. 3054. Any imported merchandise, in the original packages, which shall have been duly entered and warehoused, may be exported therefrom in conformity with law, and be transported, in the manner indicated, to ports in the adjoining British provinces, and become entitled to the benefits of those provisions. — Sect. 3056. Any imported merchandise which has been entered, and the duties paid or secured according to law, for *D.*, may be exported to the British N. American provinces adjoining the U. States.

*Internal Revenue.* Sect. 3329. *Distilled spirits* upon which all taxes have been paid may be exported with the privilege of *D.*, in quantities of not less than 1,000 gallons, and in distillers' original casks containing not less than 20 wine-gallons each, on application of the owner thereof to the collector of customs of any port of entry, and under such rules and regulations, and after making such entry as may be prescribed by law and by the Sec. of the Treasury. The entry for such exportation shall be in triplicate, and shall contain the name of the person applying to export, the name of the distiller, the name of the district in which the spirits were distilled, the name of the vessel by which and the name of the port to which, they are to be exported; and the form of the entry shall be as follows: —

*Export Entry of Distilled Spirits entitled to Drawback.*

Entry of Spirits distilled by \_\_\_\_\_, in \_\_\_\_\_ District, State of \_\_\_\_\_, to be exported by \_\_\_\_\_, in the \_\_\_\_\_, whereof \_\_\_\_\_ is master, bound to \_\_\_\_\_.

And the entry shall specify the whole number of casks or packages, the marks and serial numbers thereon, the quantity and kind of spirits as known in commerce, the number of gauges or wine-gallons and of proof-gallons; and the amount of the tax on such spirits shall be verified by the oath of the owner of the spirits, and that the tax has been paid thereon, and that they are truly to be exported to the port of \_\_\_\_\_, and not to be reloaded within the limits of the U. States. One bill of lading, duly signed by the master of the vessel, shall be deposited with such collector, to be filed at his office with the entry retained by him. One of said entries shall be, when the shipment is completed, transmitted to the Sec. of the Treasury to be recorded and filed in his office. The lading on board said vessel shall be only after the receipt of an order or permit signed by the collector of customs and directed to a customs gauger, and after each cask or package shall have been distinctly marked or branded by said gauger, as follows: "For export from U. S. A." and the tax-paid stamps thereon obliterated. The casks or packages shall be inspected and gauged alongside of or on the vessel by the gauger designated by said collector; and on application of said col-

lector it shall be the duty of the surveyor of the port to designate and direct one of the custom-house inspectors to superintend such shipments. — Sect. 3385. There shall be an allowance of *D.* on tobacco, snuff, and cigars on which the tax has been paid by suitable stamps affixed thereto before removal from the place of manufacture, when the same are exported equal in amount to the value of the stamps found to have been so affixed, the evidence that the stamps were so affixed, and the amount of tax so paid, and of the subsequent exportation of the said tobacco, snuff, and cigars, to be ascertained under such regulations as shall be prescribed by the Commissioner of Internal Revenue and approved by the Sec. of the Treasury. Any sums found to be due under the provisions of this section shall be paid by the warrant of the Sec. of the Treasury on the Treasurer of the U. States: *Provided*, That no claim for an allowance of *D.* shall be entertained or allowed for a sum less than \$50, nor except upon evidence satisfactory to the Commissioner of Internal Revenue that the stamps affixed to the tobacco, snuff, or cigars alleged to have been exported were totally destroyed before the shipment thereof, and that the same have been landed in a foreign country or lost at sea, and have not been relanded within the limits of the U. States. Sect. 25 of an act approved Feb. 8, 1875, declares, "That if any person or persons shall fraudulently claim or seek to obtain an allowance or *D.* of duties on any manufactured tobacco, or shall fraudulently claim any greater allowance or *D.* thereon than the duty actually paid, such person or persons shall forfeit triple the amount wrongfully or fraudulently claimed or sought to be obtained, or the sum of \$500 at the election of the Sec. of the Treasury, to be recovered as in other cases of forfeiture provided for in the Internal Revenue Laws." — Sect. 3441. There shall be an allowance of *D.* on fermented liquors, and on all articles mentioned in Schedule A. (*medicines or preparations, perfumery and cosmetics, and playing cards*) (see *Stamp Duties*), on which any internal tax shall have been paid, except lucifer or friction matches, cigar-tights, and wax-tapers, equal in amount to the tax paid thereon, and no more, when exported; to be paid by the warrant of the Sec. of the Treasury on the Treasurer of the U. States: *Provided*, That no allowance of *D.* shall be made for any amount, claimed or due, less than \$10. The evidence that any such tax has been paid as aforesaid shall be furnished to the satisfaction of the Commissioner of Internal Revenue by the person claiming the allowance of *D.*, and the amount shall be ascertained under such regulations as shall be prescribed from time to time by the Commissioner, under the direction of the Sec. of the Treasury. And the said Sec. may make such regulations with regard to the form of certificates of *D.* and the issuing thereof as he may deem necessary. — Sect. 3443. Whenever any person fraudulently claims or seeks to obtain an allowance of *D.* on goods, wares, or merchandise on which no internal duty shall have been paid, or fraudulently claims any greater allowance of *D.* than the tax actually paid as aforesaid, he shall forfeit triple the amount wrongfully or fraudulently claimed or sought to be obtained, or the sum of \$500, at the election of the Sec. of the Treasury. — To obtain the *D.* provided for in the foregoing sections, the exporter must, at least six hours previous to shipment, file with the collector of customs an entry in printed form to be found at every Custom-House Broker.

**Drawbar**, an iron rod used to connect a locomotive with a tender.

**Drawbridge**, a bridge that can be lifted or swung to allow masted vessels to pass, or to prevent crossing.

**Drawer and Drawee**. The former is the person from whom the direction to pay a bill of exchange emanates; the latter is the person whom he directs to pay, or on whom he draws. The expression "drawee" is correctly applicable only between drawing and acceptance. The drawer's name must appear upon the bill, either in the body of it or at the end; and his liability as a party to the bill is completed by delivery to a payee. A drawer against whom recourse is to be preserved ought to have notice of non-acceptance or non-payment. See *BILL OF EXCHANGE*, and *NOTE*.

**Drawers**, sliding boxes or cases in a table or other article of household furniture, which can easily be drawn out and returned to their places. — A close under-garment made to draw over the nether limbs.

**Drawing**, a process in the preparation of flax. See *FLAX-DRESSING*.

**Drawing-Board**, a square frame used by artists for holding a sheet of paper while plotting, projecting, etc.

**Drawing-Knife**, a blade with a handle at each end, used by joiners, coopers, etc., for shaving off surfaces; a tool used by carpenters to cut a groove for a saw to follow, to prevent excoriation of the surface of the wood.

**Drawing-Paper**, thick sized paper, generally made of linen stock, for draughtsmen and water-color painters. The usual sizes are: —

Cap.....	13	×	16	inches
Demy.....	15 1/2	×	18 1/2	"
Medium.....	18	×	22	"
Royal.....	19	×	24	"
Super-royal.....	19	×	27	"
Imperial.....	21 25	×	29	"
Elephant.....	22 25	×	27 75	"
Columbier.....	23	×	33 75	"
Atlas.....	26	×	33	"
Theorem.....	28	×	34	"
Double Elephant.....	26	×	40	"
Antiquarian.....	31	×	52	"
Emperor.....	40	×	60	"
Uncle Sam.....	48	×	120	"

**Drawing-Pen**, a pen used by draughtsmen for drawing lines of various thickness, consisting of a pair of steel blades regulated by a screw, and between which the ink is contained.

**Drawing-Pencil**, a black lead-pencil of hard quality, used for drawing.

**Draw-Link**, a contrivance for connecting railway carriages together.

**Draw-Plate**, a stout plate of shear steel, pierced with one or more holes for drawing wire through. See *WIRE-DRAWING*.

**Dray**, a low cart or carriage constructed to carry heavy burdens.

**Drayage**. See *CARTAGE*.

**Dredge**, a drag-net for taking oysters, etc.; any instrument or machine for dredging the bottom of water; a dredging-machine.

**Dredging-Box**, a tin box with perforations in the lid for sprinkling flour on meat, etc.

**Dredging-Machine**, an engine used to clear away sandbanks, and to take up mud or gravel from the bottoms of rivers or harbors.

**Dregs**, the lees or sediment of liquors; the refuse in the manufacture of tallow.

**Drench**, a term applied to any liquid medicine or mixture administered to horses and neat cattle, and chiefly to the latter.

**Dresden**. See *SAXONY*.

**Dresden Ware**. See *PORCELAIN*.

**Dressed**, a term applied to stone or other material, shaped and smoothed. — Ore prepared and fitted for use. — Skins or hides tanned and prepared for use, as leather.

**Dresser**, a mallet used by plumbers for flattening lead.

**Dress Goods**, a term applied to fabrics for the outer garments of women and children, most commonly to those made of mixed materials, as silk and cotton, silk and linen, silk and worsted, cotton and worsted, and cotton and linen, though also applicable to piece silks, printed linens, and calicoes; but the term is not used for fabrics intended for petticoats or under-garments. — *T. McElrath*.

**Dressing**, any preparation of gum, starch, size, etc., employed in stiffening or "finishing off" textile fabrics and paper. — In surgery, any application to a wound or sore, made by means of lint, linen, or leather. — In agriculture, a compost, or manure, distributed over land.

**Dressing-Case**, a box fitted with apparatus and toilet utensils for the dressing-room.

**Dressing-Gown**, a loose morning robe or wrapper.

**Dress-Maker**, a mantua-maker; one who makes ladies' dresses.

**Dreyling**, an Austrian liquid measure = 448½ gallons.

**Drier**, a material added to oil paints. See **DRYER**.

**Drift**, the course or direction of a sea-current. — The distance to which a ship diverges from her proper course, owing to currents, contrary winds, etc.; as, to make leeway *drift*. — Those parts in the sheer draught of a ship, where the rails are cut off and ended with a scroll. Pieces fitted to form the drifts bear the name of *drift-pieces*. — A term applied by shipwrights to the discrepancy between the size of a bolt and that of the hole intended to receive it; also, to the difference between the circumference of a mast and that of the hoop required to fit it. — A passage in a mine cut under the earth from shaft to shaft. — In machinery, a piece of hardened steel, notched at the sides, and made slightly tapering; it is used for enlarging a hole in a piece of metal to a particular size by being driven into it.

**Drift-Net**, a fishing-net about 20 feet deep by 120 feet long, well corked at the top, but without lead at the bottom. The size of the mesh is 2½ inches or upwards; frequently a dozen or more of these nets are attached to each other by a drift-rope.

**Drift-Wood**, wood thrown on the shore of seas or rivers.

**Drill**, a tool used for boring holes in wood, metal, stone, bones, etc. It is formed in different ways,

Fig. 143. — VERTICAL DRILLING-MACHINE.

according to the kind of hole it is required to make, and the material which it has to penetrate. Drills for boring iron have pointed heads, with sharp edges projecting from them, that cut in different directions. Those for boring wood are like an auger or large gimlet, or they are broad and flat, with a projecting spike in the centre, and cutting

edges on either side: drills of this form are called *centre-bits*. These tools are worked by a rotary motion, imparted to them by a cranked handle, having a socket and spring at one end to receive and hold the drill, and a boss at the other, against which the workman presses his chest; or by a bow of steel, with a strong piece of catgut attached to it loosely enough to admit of its being passed once or twice round a pulley, through the centre of which the tool passes. The workman presses the drill against the material that he is boring by his chest, which is protected by a plate of metal. — A *Drilling-machine* is a machine carrying a rotating tool and a means for chucking the object to be bored. — These machines differ much in size and appearance, in the mode of presenting the tool, and presenting and chucking the work. — The *Vertical machine* (Fig. 143) has a vertical rod, to the lower end of which a drilling tool can be easily affixed; the tool revolves very rapidly, and soon worms its way into any piece of metal placed beneath it. The *Radial machine* has the tool affixed to a radial arm, which is movable. Range of operation in different directions is hereby obtained. See **ROCK-DRILL**. — Also an agricultural machine for sowing seeds in rows. A great variety of drills are now in use; but that formed on the principle of lifting the grain in small cups, which empty themselves into tin tubes, by which the grain is conducted to the coulters (Fig. 144), is the most generally adopted; but when the soil is uneven, a lighter machine should be used.

**Drills**, heavy twilled fabrics of either cotton or linen. Cotton drills are largely used by farmers in the Eastern States for "hay-caps;" they also form an important article of export to the East Indies and South America. Linen drills are used for trousers stuff, for covering stair-carpets, and various other purposes. — *T. McElrath*.

**Drinking-Horn**, a cup made out of pressed horn.

**Dripping-Pan**, a tin dish for receiving the gravy and fat which drops from meat in roasting before the fire.

**Dripstone**, a filtering stone.

**Driver**, a coachman; one who drives beasts; the manager of a locomotive engine. — A storm-sail, a sailor's name for a spanker. — A piece of wood upon a weaver's spindle, which impels the shuttle through the opening in the warp.

**Driving-Band**, the strap, belt, or gearing for uniting, turning, and carrying machinery.

**Driving-Wheels**, the large wheels of a locomotive engine.

**Drogher**, a West India cargo boat employed in coasting, with long light masts and lateen sails.

**Drop**, a machine for lowering coals from railroad straths into the holds of colliers. — A confection, of which the principal basis is sugar. Drops differ from lozenges chiefly in the ingredients being combined by the aid of heat. Occasionally they are medicated.

*Preparation.* Double-refined sugar is reduced to powder, and passed through a hair sieve (not too fine), and afterwards through a gauze sieve, to take out the fine dust, which would destroy the beauty of the drop. It is then put into a clean pan, and moistened with any favorite aromatic, as rose or orange-flower water, added slowly, stirring it with a paddle all the time, from which the sugar will fall, as soon as it is moist enough, without sticking. The coloring (if any) is next added, in the liquid state, or in very fine powder. A small, polished copper, or tinned-copper pan, furnished with a lip, is now one half or three parts filled with the paste, and placed over the fire, or over the hole of a stove, or preferably on a sand bath, and the mixture stirred with a little bone or glass spatula until it becomes liquid. As soon as it almost boils, it is taken from the fire, and if it is too moist, a little more powdered sugar is added, and the whole stirred, until it is of such a consistence

as to run without too much extension. A tin plate, very clean and smooth, and very slightly oiled, being now ready, the pan is taken in the left hand, and a bit of bright iron, copper, or silver wire, about 4 inches long, in the right. The melted sugar is next allowed to fall regularly on the tin plate, the wire being used to remove the drop from the lip of the pan. In two or three hours afterwards the drops are taken off with the blade of a knife, and are at once put into bottles or tins. On the large scale, "confectionery drops" are moulded by a machine consisting essentially of two metal rollers covered with hollows. A sheet of the warm and soft composition, on being passed between the rollers, is at once converted into a batch of symmetrical drops, the upper and lower halves being moulded by the corresponding hollows of the upper and lower rollers.

**Drosky, Droitzschka**, a Russian low four-wheeled carriage, somewhat resembling a sledge.

**Drosometer**, an instrument by which is ascertained the quantity of a night's dew-fall. It consists of a balance, one end of which is furnished with a plate to receive the dew, while the other contains a weight protected from it.

**Dross**, the waste matter thrown off by metals during the process of smelting; also, generally the excrementitious dregs, remains, or refuse of any substance.

**Drug**, an article of slow sale, or in no demand in the market. — A name applied to all animal and vegetable products used in pharmacy; the raw material from which medicines are compounded.

Fig. 144. — ENGLISH GRAIN-DRILL.

*Imp. duty*: crude *D.*, not otherwise provided for, 20 per cent; crude *D.* for dyeing or tanning, free. See **DRAWBACK**, and **STAMP-DUTIES**.

**Inspection of Drugs and Medicines**. By an act of Congress, passed June 26, 1848, to prevent the importation of adulterated and spurious drugs and medicines, it is provided, that all drugs and medicines, medicinal preparations, including medicinal essential oils and chemical preparations used wholly or in part as medicine, imported into the U. States from abroad, shall, before passing the custom-house, be examined and approved, as well in reference to their quality, purity, and fitness for medicinal purposes as to their value and identity specified in the invoice. — Also, that all medicinal preparations, whether chemical or otherwise, usually imported with the name of the manufacturer, shall have the true name of the manufacturer, and the place where they are prepared, permanently and legibly affixed to each parcel, by stamp, label, or otherwise; and all such medicinal preparations, imported without such names affixed as aforesaid, shall be adjudged to be forfeited. — That if, on examination, any drugs, medicines, medicinal preparations, whether chemical or otherwise, including medicinal essential oils, are found, in the opinion of the examiner, to be so far adulterated, or in any manner deteriorated, as to render them, in strength and purity, inferior to the standard established by the pharmacopœias and dispensaries of the U. States, Edinburgh, London, France, and Germany, and thereby improper, unsafe, or dangerous to be used for medicinal purposes, a return to that effect shall be made upon the invoice; and the articles so noted shall not pass the custom-house, unless, on re-examination of a strictly analytical char-

acter, called for by the owner or consignee, the return of the examiner shall be found erroneous; and it shall be declared, as the result of such analysis, that the said articles may properly, safely, and without danger, be used for medicinal purposes. — That the owner or consignee shall at all times, when dissatisfied with the examiner's return, have the privilege of calling, at his own expense, for a re-examination; and depositing with the collector such sum as the latter may deem sufficient to defray such expense, it shall be the duty of that officer to procure some competent analytical chemist possessing the confidence of the medical profession, as well as of the colleges of medicine and pharmacy, if any such institutions exist in the State in which the collection district is situated, a careful analysis of the articles included in said return, and a report upon the same, under oath; and in case the report, which shall be final, shall declare the return of the examiner to be erroneous, and the said articles to be of the requisite strength and purity, according to the standards referred to in the next preceding section of this act, the entire invoice shall be passed without reservation, on payment of the customary duties; but in case the examiner's return shall be sustained by the analysis and report, the said articles shall remain in charge of the collector, and the owner or consignee, on payment of the charges of storage and other expenses necessarily incurred by the U. States, and on giving of bond, with sureties satisfactory to the collector, to land said articles out of the limits of the U. States, shall have the privilege of re-exporting them at any time within the period of six months after the report of the analysis; but if the said articles shall not be sent out of the U. States within the time specified, it shall be the duty of the collector, at the expiration of the said time, to cause the same to be destroyed, holding the owner or consignee responsible to the U. States for payment of all charges, in the same manner as if said articles had been re-exported.

**Drugget**, a coarse flimsy woollen fabric, printed or plain, chiefly used for carpeting and packing. It is largely manuf. in the U. States and in England.

**Druggist**, properly one who buys or sells drugs, a wholesale dealer; but commonly applied to one who combines the retail business of chemist and druggist, and sells, besides, various miscellaneous surgical articles in common demand.

**Drug-Mill**, a mill where drugs, etc., are crushed and ground.

**Drum**, a military musical instrument, commonly made of thin cylinders of wood, hollow within, and covered at the ends with sheets of vellum, which may be stretched or slackened at pleasure by means of small cords and sliding-knots; it is beat upon with a pair of short sticks, one in each hand of the performer. *Kettle-drums* are hollow hemispheres made of brass, and are used in pairs; one of them being tuned to the key-note, and the other to the fifth of the key. Small *D.*, hanging from the drummer's belt at the side, and beaten with the *chamade* or *ronde*, are styled *solo-drums*. — A hollow cylinder which, fixed in position on a shaft, communicates motion to another shaft by means of a revolving leather or gutta-percha band. — A hollow and thin chamber of a cylindrical form, used in heaters, stoves, and flues. It generally forms a mere casing, but in some cases, as steam-drums, is adapted to stand considerable pressure. — A cylindrical box in which dried fruit is sold, weighing when full from  $\frac{1}{2}$  to  $\frac{3}{4}$  of a cwt.

**Drumhead**, the top of a capstan, containing the holes in which the capstan bars are fixed. — The parchment or vellum skin stretched on the top of a drum.

**Drummond Light**, a very intense light produced by projecting a blowpipe flame of mixed oxygen and hydrogen gases upon a ball of lime, the intense heat raising the lime to vivid incandescence. One of the most convenient forms of apparatus for its production is represented in Fig.

145, when the mixed gases escaping by the jet, *a*, being set fire to and made to impinge upon the cylinder of lime, *b*, raise the surface of the latter nearest the jet to a white heat, accompanied by a dazzling light. As minute portions of lime become detached and are volatilized from the spot on the lime on which the jet of burning gases

FIG. 145. — DRUMMOND LIGHT.

strikes, it is necessary to expose a new surface of lime to the gases, and for this purpose the screw, *c*, may be turned by the hand or by clock-work. Owing to the great explosiveness of a mixture of hydrogen and oxygen gases, special precautions are required. The hydrogen and oxygen ought to be confined in separate gas-holders or bags, and to be brought by different tubes, *H* and *O*, provided with separate stop-cocks, to within a short distance of the exit jet. The common tube through which the mingled gases pass to the jet is about 9 inches long by  $\frac{3}{8}$  of an inch in diameter; and in Mr. Hemming's construction (called *Hemming's jet*) the tube is tightly packed with fine wires through which the mixed gases have to pass on their way to the jet, and which, when the pressure is deficient, prevent the return of the flame, which might lead to disastrous explosion. *D. L.* is often called *Lime Light*; it is also called *Magnesia Light* or *Zirconia Light*, when magnesia or zirconia are used instead of lime. In the *Oxyacalcium Light* a jet of oxygen gas is blown through a spirit-flame upon a ball of lime. When a coal-gas flame replaces the spirit-flame it is sometimes called *Oxy-coal-gas Light*. The general name for all these lights is the *Oxyhydrogen Light*.

**Dry Dock.** See Dock.

**Dryer,** a substance, as litharge, sugar of lead, white copperas, etc., employed, as the name implies, to increase the drying and hardening properties of oil paints.

**Dry-Goods,** a commercial name for textile fabrics, cottons, woollens, silks, laces, etc.

**Drying-Machine.** In many departments of manufacture, such as bleaching, calico-printing, dyeing, paper-making, etc., substances are dried quickly by being put into a hollow drum or cylinder, and rotated with great velocity. The moisture driven from the substance by centrifugal action escapes through holes in the drum into an outer case or receptacle.

**Drying-Oils,** linseed and other oils which, having been heated with oxide of lead, dry quickly on exposure to the atmosphere and retain their transparency on solidifying. *D.-O.* are essential for the purposes of the painter and for the manufacture of printing-ink; they also form the basis of many paints and varnishes. Castor-oil, linseed-oil, poppy-oil, and walnut-oil are among the *D.-O.*

**Dry Measure,** a standard of quantity, by which dry, coarse, or bulky articles are measured.

**Drying-Stove,** a stove used by laundresses; also one employed by foundries and others.

**Dry-Rot,** a decay in timber; a disease which attacks wood, and renders it brittle, by destroying the cohesion of its parts. See TIMBER (PRESERVATION OF).

**Dry-Salter,** a dealer in the minerals used in pickling, salting, and preserving various kinds of food. Also in gums, drugs, dye-stuffs, mineral colors, tanning substances, artificial manures, etc.

**Dry-Stove,** a glazed structure designed for the protection of the plants of dry, arid climates; a hot-house in which the air is kept less moist than in the bark-stove. It is particularly adapted to succulent plants. The temperature should be higher than that of a greenhouse.

**Dry-Wines** are wines in which the saccharine matter and the ferment are so exactly balanced that they have mutually decomposed each other, and no sweetness is perceptible.

**Dualin,** an explosive compound, composed of nitro-glycerine mixed with saw-dust, or wood-pulp, such as is used in paper-mills; the latter being first treated with nitric and sulphuric acids. The object of the mixture is to diminish the danger connected with the storage and transportation of nitro-glycerine.

**Dubber, Dupper,** a leather bottle or skin bag, used chiefly in India for holding oil, ghee, and other liquids, and capable of holding, according to size, from 20 to 80 lbs. weight.

**Dubbing,** a greasy composition used by the curriers to dress leather, and by shoemakers and others to soften leather, and to render boots and shoes water-proof. A good *D.* is prepared by boiling to a proper consistence 2 lbs. black resin, 1 lb. tallow, and 1 gallon crude cod oil or train oil.

**Dublin.** See GREAT BRITAIN.

**Dubuque and Sioux City R.R.** runs from Dubuque to Iowa Falls, Ia. This Co., whose offices are in Dubuque and New York City, was formed upon the sale, under foreclosure, in 1860, of the Dubuque and Pacific R.R. It was opened to its present terminus in 1866, and in 1867 was leased for 20 years to the Illinois Central R.R. Co., for 35 % of the gross earnings for the first 10 years and 36 % for the other ten, and payment of all taxes and assessments. The Illinois R.R. Co. may, at the expiration of the first lease, take a perpetual one for 35 % of the gross earnings. *Financial statement, 1878:* Cap. stock, \$5,000,000; 1st mortgage tax-free bonds, \$882,000, payable 1883 and 1894, int. 7 % (Jan. and July).

**Dubuque and Southwestern R.R.** runs from Farley, Ia., to Cedar Rapids, Ia. This Co., whose offices are in Dubuque, leased the road, which was opened in 1864, to the Chicago, Milwaukee, and St. Paul R.R. Co. in 1878. *Financial statement:* Cap. stock, common, \$588,400, preferred, \$589,000. Funded debt, \$548,415, consisting of 1st mortgage bonds, \$78,500, payable July, 1883, int. 7 %; 1st mortgage bonds, \$450,000, payable October, 1883, int. 7 %; funded coupons, \$19,915, payable 1879 and 1880, int. 7 %.

**Duchess-Slates,** large sized-slates, 24 by 12 inches.

**Duck,** a linen or cotton fabric lighter and finer than canvas, used for small sails, seamen's trousers, etc. The American cotton *D.* is 22, 28 $\frac{1}{2}$ , 29, and 40 inches in width. — A water-fowl, wild and domesticated, much esteemed as food.

**Ductility,** a property belonging chiefly to certain metals, by which they are capable of being drawn out into wire; that is, of being increased in length and diminished in thickness without fracture. The most ductile substances with which we are familiar, are gold, silver, platinum, iron, and softened glass. Wollaston obtained a platinum wire of 0.00003 of an inch in diameter, by first coating a fine platinum wire with silver, and drawing the cylinder thus formed into as fine a

wire as possible, and then dissolving the silver in dilute nitric acid. By this means a platinum wire was obtained having a diameter so fine that 1,000 yards of it weighed only  $\frac{1}{4}$  of a grain. See **MALLEABILITY**.

**Due-Bill**, an acknowledgment of a debt in writing, not transferable like a promissory note by mere indorsement.

**Duffels, Duffields**, a thick coarse kind of woolen cloth having a thick nap or frieze.

**Dugong**, a name in Australia and the Indian Ocean for the *Halicore dugong*, a marine animal which is taken for the oil obtained from the blubber. This oil is asserted to be equal to cod-liver oil, and is a cure for diseases of the ear. The bone of the animal, in fineness and hardness of grain, specific gravity, and appearance, approaches nearly to the nature of ivory. The flesh of the dugong is often eaten.

**Dulcamara**. See **NIGHTSHADE (WOODY)**.

**Dulcimer**, a small musical instrument consisting of a triangular chest, strung with wires, which are struck with a little rod held in each hand.

**Dumb-Bells**, heavy metal weights swung in the hands for exercise, to open the chest and increase muscular strength.

**Dumb-Singles**, a kind of silk merely wound and cleaned.

**Dumb-Waiter**, a stand with shelves placed on

Fig. 146. — DUMB-WAITER.

a movable frame (Fig. 146), enabling viands, etc. to be passed from one story of a house to another; thus dispensing with the attendance of servants for that purpose.

**Dummy**, a sham copy of an original packet or package of any salable commodity.

**Dump**, to throw down violently, as in emptying a cart by tilting it over.

**Dumping-Cart**, a cart that may be tilted over, to free it from its contents.

**Dumpy**, short and thick.

**Dumpy-Level**, a spirit-level with a telescope for surveying purposes.

**Dundee**. See **GREAT BRITAIN**.

**Dunder**, the fermenting lees of cane-juice, used in the distillation of rum.

**Dunfish**, codfish cured in such a manner as to produce a dun, brown color.

**Dung**, the excretory deposit of animals; a general name for farmyard or stable manure. The dung of most animals possesses a commercial value; that of dogs and of pigeons is used in tanning, horse-dung in foundries, that of cows in calico-printing.

**Dungallie**, a small liquid measure in the East of 24 seers; 11½ dungallies making one choradang, = 1¾ quart.

**Dungaree, Dungary**, a coarse kind of unbleached Indian calico.

**Dunghill**, a waste heap of ashes, refuse substances of manure, etc.

**Dunghill-Fork**, a prong for lifting or turning straw, manure, etc., in a farm or stable yard, etc.

**Dunging**, one of the principal processes in the

arts of calico-printing and dyeing, its object being to free the cloth from loose matters which would interfere with the dyeing.

After the thickened mordants have been applied to the fabric and properly fixed, it is necessary to remove the now useless thickening matter, together with the excess of mordant, which has not come into actual contact with the cloth. Formerly a bath formed of cow-dung, diffused through hot water (130° to 212° F.), was always used to wash away these loose matters; but now various manufactured substances are successfully employed for the purpose. The best dung substitutes are the arsenite and arsenate of soda, the silicate of soda, and phosphate of lime. Experience proves that, in the case of these substitutes, a final rinse in cow-dung, before dyeing is advantageous. A process very similar to "dun-ning" is employed after dyeing, to clear and give purity to the undyed parts. This subsequent process is distinguished by the term "clearing." Cow-dung has been used in "clearing" operations, but its employment is not to be recommended. Bran scalded and mixed with water is employed for certain goods, but bleaching-powder is the most generally used "clearing agent."

**Dunkerque, Dunkirk**. See **FRANCE**.

**Dunkirk, Alleghany Valley, and Pittsburgh R.R.** runs from Dunkirk, N. Y., to Titusville, Pa., 90.60 m. This Co., whose offices are in Dunkirk, was formed in 1872 by the consolidation of the Dunkirk, Warren, and Pittsburgh and the Warren and Venango R.R. Cos. It is leased by the N. Y. Central and Hudson River R.R. Co., which pays interest on the funded debt as rent. *Financial statement*: Cap. stock, \$1,300,000; funded debt, \$3,200,000, consisting of 1st mortgage 7% 20-year bonds payable 1890, \$2,000,000; 2d mortgage 7% 20-year bonds payable 1890, \$1,000,000; 3d mortgage 7% 20-year bonds payable 1890, \$200,000. Annual charge, \$224,000. Net deficit for 1878, \$645.30.

**Dunlop Cheese**. See **CHEESE**.

**Dunnage**, a name given to the pieces of loose wood placed on the bottom and sides of a ship's hold, either to support the cargo, so that the vessel may be properly ballasted, or to prevent injury from leakage.

**Dunning**, a common term for urgent pressing for the payment of a debt. — Also a mode of curing codfish, so as to give them a partial color.

**Dunstable Straw**, wheat straw used for bonnet plait, and so called from having been first manufactured in Dunstable, a town of England. The middle part of the straw above the last joint is selected; it is cut into lengths of about 10 inches, which are then split by a single machine into slips of the requisite width. Whole *D.* signifies that the plait is formed of seven entire straws, while patent *D.* consists of fourteen split straws.

**Dunter-Goose**, a name given to the eider-duck.

**Duodecimo**, a volume formed by folding the sheet into 12 leaves, making 24 pages. It is written, for shortness, 12mo.

**Dupion**, a double cocoon formed by two silkworms.

**Duplex**, twofold or doubled; as a *D. lathe*, or one that turns two sets of cutting tools at the same time; a *D. watch*, or one that has a double escapement.

**Duplicate**, a second article of the same kind. — A copy or transcript.

**Durma Mats**, mats made in India of the split stalks of the nul or nar, a grass of Bengal.

**Duro**, the hard dollar of exchange of Spain, of 20 reals.

**Duroy**, a cheap kind of figured serge.

**Dust-Brush**, a light feather or hair brush for cleaning rooms and furniture.

**Dust-Pan**, a broad, flat, tin shovel, to catch crumbs, lint, or dust, as they may be brushed from a table-cloth or carpet.

**Dutch-Carpet**, a mixed material of cotton, flax, and wool, used for floor coverings.

**Dutch-Cheese.** See CHEESE.

**Dutch Gold-Leaf** (also called *brass-foil*, *bronze-leaf*, *Dutch-foil*, *Dutch-metal*), an alloy of copper and zinc, closely resembling common brass, but having rather less zinc in its composition than brass generally has. It is used for beating into thin plates resembling gold-leaf in appearance when new, and used for ornamentation instead of gold-leaf. It tarnishes readily, and may be tested by the application of strong nitric acid, which will not injure gold-leaf, but which readily dissolves the imitation. *Imp. duty*, 10 per cent.

**Dutch-Oven**, a tin hanging screen for cooking before a kitchen range or ordinary fire-grate. — In the U. States, a pot used in baking between hot coals.

**Dutch-Pink**, a painter's bright yellow color used in distemper, in paper-staining, etc. It consists of a mixture of clay and chalk, colored by French berries or birch-leaves, with alum. *Imp. duty*, 25 per cent.

**Dutch-Rush**, the horsetail or shave-grass, *Equisetum hyemale*, a plant which, from its hard and rough exterior surface, is found useful for polishing marbles, hard woods, ivory, brass, and other substances. The rhizomes are nutritious, and have been used as food in times of famine.

**Dutch-Tiles**, glazed and painted ornamental tiles; formerly much used to plaster up in the jambs of chimneys.

**Dutiable**, liable to duty; subject to the imposition of customs-duty.

**Duty**, a general name for a tax or impost; particularly, a sum of money required to be paid to a government on the importation, exportation, or consumption of goods or merchandise. — The amount of work performed by a steam-engine, or other machinery.

**Duvet** [Fr.], down or fine feathers.

**Dwt.**, the abbreviation for pennyweight.

**Dye**, a coloring liquid or matter.

**Dyeing**, the art of coloring in a permanent manner porous or absorbent substances by impregnating them with coloring bodies. Most vegetable and animal bodies are porous or absorbent, and can be dyed; some minerals also, such as marble, can absorb liquid coloring matters; but the term *D.* is usually confined to the coloring of textile fibrous materials by penetration. Although many eminent chemists have worked and written upon the subject, there still remains much difference of opinion as to what actually takes place in *D.* operations. The following general account of the chief cases of *D.* will illustrate the principal methods in use, and serve as an introduction to a description of actual processes practised in dye-houses. The simplest cases of *D.* are those in which only two substances are employed, — the fibre to be dyed and the coloring matter, — and where the process of *D.* consists in nothing more than leaving the two materials in contact for a certain time at a convenient temperature. Of natural coloring matters few can be practically used in this simple way without some previous chemical treatment. The artificial coloring matters from aniline, however, illustrate this kind of *D.* very well. To obtain the finest shades of mauve, magenta, purple, and numerous other colors upon wool and silk fibre, the whole process consists in placing the material in a solution of the requisite color and of sufficient quantity to give the desired shade; it absorbs the color, becoming dyed, while the solution is rendered nearly colorless. During

the process the fibrous material is kept in a constant state of movement, so that the dye solution shall have equal access to all portions, the temperature employed and time allowed being regulated according to the necessities of the case. The color absorbed by the fibre has entered into an intimate state of combination with it, since it cannot be washed out again; a true *D.* has taken place. Besides the aniline colors, the older artificial dyes — sulphindigotic acid, picric acid, and one or two others — have the same property of combining directly with wool and silk. There are other cases of *D.* closely resembling the foregoing, in which the resulting dyed stuff may be considered as being a binary compound of fibre and coloring matter, but in which the methods of application are less simple. These may be taken generally as consisting in the use of materials or processes which bring a previously insoluble coloring matter into a soluble state; thus the pink colors of safflower are obtained by the action of an alkali; and the dyes yielded by archil, arnotto, and indigo are also the result of the action of solvents. It is possible that during the process of solution important internal changes may take place in the composition of the above dyes; but if so, they are only of a temporary nature, for there is no reason to suppose that the coloring matter attached to the fibre differs in chemical composition from that which is free. With regard to nearly all other coloring matters, the above simple processes are quite powerless to induce a permanent combination with the fibre. Let wool or silk be immersed at boiling temperature in decoctions of any of the best known natural dye-stuffs, such as cochineal, logwood, madder, quercitron bark, etc., and then washed in water, it will be found that the fibres are simply discolored, or stained of no definite shade; they have taken up but a small portion of color from the decoction, and no real *D.* has taken place. To obtain permanent dyes from the great majority of native coloring materials the intervention of another class of bodies entirely different from either fibrous or coloring matter is found necessary; these bodies are called *mordants*. The chief mordants used in *D.* are salts of aluminium, iron, tin, chromium, copper, and a few other metals. When a decoction of a coloring matter, say logwood or cochineal, is heated with a small quantity of a properly chosen salt of one of those metals, it is found that the coloring principle loses its solubility, forms a combination with the metallic salt or its bases, and precipitates to the bottom of the solution, leaving the supernatant liquid nearly or quite colorless. The precipitate is usually called the *lake* of the particular metal and coloring matter, which are probably in a state of chemical combination. Fibre cannot usually be dyed by means of ready formed lakes, for the reason that they are insoluble in water and not easily soluble in any menstruum which can be safely applied to such material; they are themselves of too coarse and gross a nature to penetrate the fibre, and when applied to it rest for the most part on the surface, and are therefore easily removable by washing or mechanical friction. It is known, however, that for some colors in calico-printing lakes can be applied, but that is only in conjunction with acid salts and at a high temperature, by means of which a sort of solution is obtained while in contact with the fibre itself. The art of the dyer consists in so arranging these three elements — fibre, metallic salts, and coloring matter — that he may obtain the formation of the insoluble colored lake in the body of the fibre itself, whereby

either by the lake being mechanically retained or chemically combined the fibre is permanently colored.

**Application of Mordants.** There are three principal ways in which the mordant and coloring matter can be put into contact with the fibre, the developments and modifications of which constitute the whole art of *D.* — 1. By the first method, which is by far the most common, the fibrous matter is separately impregnated with the mordant, which is by various means decomposed, so as to deposit its base in an insoluble state upon or within the fibre, and afterwards the coloring matter is applied. Take, for instance, the case of *D.* a common black from logwood upon calico, which has no affinity for the coloring matter of the logwood. The first process is to pass the calico through a hot aqueous solution of sulphate of iron, sometimes mixed with acetate of iron, and to remove the excess by passing the cloth through rollers (Fig. 147); the cloth, either previously dried or not, is then passed through a mixture of lime and water, which has the effect of decomposing the iron salts and liberating oxide of iron. A washing in water to remove the excess of lime, or any loosely attached oxide of iron, prepares the calico for coming into contact with the logwood. The calico, which has now a buff color, owing to the attached mordant of oxide of iron, when placed in a hot decoction of logwood speedily acquires a dark hue, and in about half an hour has become dyed of a dense black color, and, when smoothed and finished, forms the common black calico of the shops. — 2. A second method is to apply the coloring matter before the

Fig. 147. — MORDANTING AND DYEING PROCESS.

mordant in the dye-vat (Fig. 148). It is resorted to only with heavy goods, which absorb a great quantity of liquid, and with light colors upon other fabrics; dyes produced in this way are superficial in their character, and not so permanent as those produced by the first method. In *D.* by that method, it is in many cases customary to add a small quantity of mordant to the dye-bath when the process is quite or nearly finished, or to pass the dyed goods, as a final operation, through a diluted mordant. — 3. A third method is to apply the mordant and the coloring matter together to the fibrous substance. In common piece *D.* in weak liquids this plan is seldom followed, on account of the tendency to form insoluble lakes in the solution, which, depositing only on the external part of the fibres, give inferior results, alike as to stability of color, depth of shade, and evenness or regularity of the dye. In calico-printing, or in puddling, this method is of extended application, and the inconveniences experienced in common *D.* are not perceptible, owing to the greater concentration of the mordanting salts and the use of thickening matters.

**Red Colors.** The most important of the red colors produced by *D.* are obtained from cochineal and from madder, the former being used for woollen and the latter for cotton goods. They are both old colors, and have arrived at their present excellence by slow degrees; they are deep and brilliant, and, as far as regards permanency, hold the highest position among all dyed colors. The processes employed are instructive, as illustrating the diversity of treatment required by different fibres and coloring matters.

**Red upon wool from cochineal.** Let it be assumed that the shade of red required is fine scarlet, and that the woollen cloth is of finest quality. The cloth first requires purifying from all the adventitious substances which it has acquired in the process of manufacture, in order to prevent irregularity and unevenness in the shade of color: this is done by methods described in the article BLEACHING. The only materials required to produce a fast scarlet upon wool are oxide of tin and

the coloring matter of cochineal, but it requires much practical skill to bring them into contact properly. After the cloth is cleaned, and while it is still wet from its last washing, it is mordanted by boiling it in a solution of a salt of tin with or without cream of tartar. The parts of the boilers not in actual contact with the fire are frequently constructed of pure block tin, or at least all parts out of water should be of this metal, or else protected by wood, or the *D.* vessels should be made entirely of wood and heated by steam-pipes; for, if the cloth containing the acid solution of tin comes in contact with a copper or brass surface, it acquires a stain which afterwards dyes up an impure color. What takes place in the course of boiling is that eventually a certain portion of tin, probably in the state of stannic oxide, becomes fixed upon or within the fibres of the wool, and this in a perfectly uniform manner. The tin not in intimate combination with the wool, or held merely by capillary attraction, is washed off by water before the cloth is brought into contact with the coloring matter. The mordanted cloth is now brought into a boiler containing finely ground cochineal diffused through a sufficient quantity of water, to which it is usual to add some more tin mordant and tartar; the cloth is turned continually to prevent folds or creases from interfering with the free access of the dye to all parts of it. The contents of the boiler are heated to the boiling point, and in half an hour or so the liquid becomes nearly colorless, and the cloth is found dyed of a bright red. — The above may suffice to furnish a general view of the procedure usually followed, and to illustrate the principles involved with regard to numerous other dyes besides cochineal. To give the general reader a further idea of certain operations practised in the use of that color (and the description applies more or less to others), the following particulars may be cited.

**The tin mordant used for scarlet on wool.** It is now 200 years since the discovery was made of the use of tin with cochineal for dyeing scarlet. It might be thought that by this time the exact kind and quantity of tin solution to be used would have been settled. There exists, however, the greatest diversity upon this point among practical dyers. The two salts of tin met with in commerce, designated by chemists stannous and stannic chlorides, have received various names from dyers. Crystallized stannous chloride is generally known as "tin crystal;" the solution of the same as "muriate of tin." A single muriate and a double muriate of tin are also distinguished, the difference being in the degree of concentration. Experience teaches the dyer that there are scarcely two dye-works in the world in exactly the same condition with regard to either water and air, or apparatus, or quality of materials, and that the nature and quantities of drugs, mordants, and dye-stuffs used, and the duration and temperatures of the operations which secure admirable results in one place are altogether unsuitable in another. It is, however, clear that by far the greater part of the variations introduced by practical dyers are not really founded upon necessity. Thus, although the best colors can be obtained by the use of simple tin solutions manufactured on the large scale, in nine cases out of ten the operative dyer of scarlet insists upon preparing his own solution, and pretends that he employs special methods and preparations without which it would never be fit to use; and hence a countless number of tin solutions are in use. The solution of tin used by dyers for the scarlet, and for many other colors upon wool, silks, and cotton, are commonly called *sprits*, or *tin spirits*, a name which is very old, and appears to have originated in the use of nitric and hydrochloric acids to dissolve the tin, which acids were formerly, and are even at present, called *sprits of nitre* and *sprits of salts*.

**Use of tartar along with tin mordant.** The tartar of the dyer is a more or less impure form of the cream of tartar of the shops, or the acid potassium tartrate of chemists. It is in very general use for wool dyeing, and when employed with dye-stuffs plays the part of an acid, and could in fact be replaced by an acid; in other cases, when used in mordanting, it no doubt acts as a salt, contributing to neutralize the strong mineral acids of the mordant, and rendering them more ready to decompose in the presence of the cloth. In a particular receipt for dyeing scarlet the proportions of materials are as follows: 20 lbs. of tin solution, containing about 20 ounces of metallic tin dissolved in nitric acid, with the addition of a little common salt, are used to 100 lbs. of woollen cloth. Of the 20 lbs. of mordant, 13 lbs. are taken and mixed with a solution in water of 8 lbs. of crude tartar, and about 8 ounces of cochineal are added, to enable the dyer to form a judgment of the progress of the mordanting. The ingredients having been boiled for a couple of hours, the cloth is rinsed in clean water and placed in another boiler, containing the residual 7 lbs. of mordant and 6 lbs. of ground cochineal, which are sufficient to dye up a full scarlet color; but if the scarlet is required to be very bright, or what is called "fiery" colored, a further quantity of tartar is added; this has the effect of somewhat reducing the depth of color, and at the same time giving it a yellowish or orange hue, which for certain purposes is much desired.

**Use of yellow in scarlet.** It appears that Bancroft, who wrote about the end of the last century, was the first to suggest that the bright fiery scarlet, which the dyers found they could best obtain by using a large quantity of tartar, might be

produced more cheaply by adding some yellow coloring matter to the cochineal, or by first dyeing the cloth a light yellow, he tried the yellow from quercitron bark, and succeeded as far, perhaps, as was possible with that material. At any rate, from his time it has been customary for dyers who do not aim at the highest degree of excellence in the scarlet color to use a purified preparation of quercitron bark, commercially known as flavine, in conjunction with cochineal, other yellow coloring matters, such as fustic and turmeric, are also used. An admixture of these substances cheapens the cost of the color, which can be made nearly equal in appearance to that obtained with cochineal alone, but it does not stand wear so well, and is more readily stained by various influences. The best scarlets are still dyed exclusively with cochineal.

*Scarlets on wool from lac-dye.* The coloring matter of lac-dye is, in its chemical properties and composition, very similar to, if not quite identical with, that of cochineal. As it is imported into this country from India, it is, however, less pure than average qualities of cochineal; and it is probably on account of its impurities that the dyer cannot obtain quite so good results as the best cochineal colors, although if skillful he may approach them very closely. Having been submitted to a preliminary treatment with acid, to free it from alumina and other earthy matters used in its preparation, it is then applied exactly in the same way as cochineal. It is extensively used for a second-class scarlet, and is believed to be somewhat more durable and stable even than cochineal.

*Crimson red on wool.* This color is also dyed with cochineal, but with a mordant of alum instead of tin. It is a far less important color than the scarlet, and compared with it is dull and flat; it is, however, rich and durable, and combines excellently with other colors.

The mordanting of cloth by means of alum, an operation of capital importance for a large series of colors derived from all varieties of dye-stuffs, must now be noticed.

*Aluming of wool.* The method of mordanting with alum, generally called aluming, is practically a simple process, but the chemical principles involved have given rise to much debate amongst experimenters. The aluming is usually performed by boiling the wool for one or two hours in a solution of common alum mixed with tartar; a certain portion of alumina, or, it may be, of some compound of aluminium, becomes thus intimately combined with the wool, and forms a basis upon which a colored lake may be produced with solutions of coloring matters. The chemical conditions are somewhat different here from those which obtain in the case of mordanting with tin, for the disposition of tin salts in dilute solutions to decompose even spontaneously is so manifest that it may readily be supposed that some action on the part of the wool takes place which induces the formation of oxide of tin. The wool being successfully alumed acquires a crimson color by dyeing in cochineal, but this shade is not of much value. The shade of red between scarlet and crimson reds proper, or cherry reds, are also dyed with tin mordant and cochineal in nearly the same way as the scarlet; but in order to avoid a yellowish tone, the natural cochineal may be mixed with the manufactured or modified material known as ammoniacal cochineal.

*Pink or rose color upon wool.* This shade is obtained from ammoniacal cochineal, mordanting previously in a mixture of tin solution, alum, and tartar; the quantity of tin mordant used is small, the alum being the essential basis.

*Madder red upon wool.* This color is wanting in brightness, but it is valuable for its stability. As a basis for browns, chocolates, and other dark colors, it is very suitable when its comparatively high cost is not an objection. To obtain madder red, the wool is boiled for two hours with a mixture of alum, tartar, and tin salt, — 3 lbs. alum, 1 lb tartar, and 4 ounces of the tin solution being taken for 10 lbs. of cloth. After boiling, the cloth is rinsed in water to remove uncombined mordant, and then dyed with madder, or preferably its derivative garancin, with addition of a portion of tartar; the dyeing may be accomplished in an hour, the depth of color varying with the amount of coloring matter used.

*Artificial alizarin on wool.* By employing artificial alizarin somewhat better shades of color can be obtained, and even pink colors of much solidity produced. A process for obtaining a fast red on woollen yarn, from alizarin, is as follows: Boil 10 lbs. wool for an hour and a half with 1½ lbs sulphate of alumina and ½ lb. tartar; rinse in water, and then dye with 6 to 7 ounces of artificial alizarin paste containing 10 per cent of dry matter: commence the *D.* cold, and gradually heat to boiling. Alizarin can be used as a basis for producing fast brown shades, by adding fustic and extract of indigo after the red has been developed, and if necessary, a further quantity of sulphate of alumina and tartar.

*Aniline reds upon wool.* There are several artificial red dye-stuffs which may be used for wool, but none possesses great excellence. The only one which resembles cochineal in its qualities is the recently discovered *rosine*; this, with an alumina mordant, gives upon wool a very good imitation of cochineal scarlet, but an imitation only, for the color fades rapidly in sunlight, and is easily washed out by soap and water. Substances similar to eosine, which have even still more recently appeared in trade, are called *corrine* and *nopaline*; they yield beautiful but perishable red colors on wool and silk.

*Red colors on cotton. — Turkey red.* Cochineal, which is so suitable a coloring matter for wool, does not dye satisfactory colors upon vegetable fibres; but from very remote times the Hindus have possessed a process for dyeing a brilliant and extremely permanent red upon fabrics by means of madder. The name Turkey red, or Adrianople red, was applied to calico dyed with it at the time that such goods could be obtained only from the East, and it still retains the name. The dyeing of Turkey red upon cloth and yarn is now extensively carried on in Great Britain, and with great success. Turkey red is essentially a madder red with an aluminous basis, but differs from a common madder red by containing oil, and it is the fixing and combining of the oil with the fibre and the color which constitutes its peculiarity. Divested of details, the process of producing Turkey red may be divided into four stages: 1, the oiling of the cloth; 2, mordanting with a salt of aluminium; 3, *D.* with madder; 4, the brightening of the dyed color. The preparation of the cloth with oil is a process used in no other kind of *D.*; of its utility there can be no doubt, but all the attempts of chemists to explain the *rationale* of its action have failed. There are many modifications of the method of applying the oil, but the older and more commonly used process is to mix the oil with a dilute solution of potash or soda ash, so as to diffuse it uniformly through the liquid, forming an emulsion; the oil is not dissolved by the alkalies, nor is it supposed to combine with them, but is simply held in a state of excessively fine mechanical division. A low quality of olive oil is most generally used in Europe. Certain kinds of oil do not answer for Turkey red, only those being suitable which, probably from containing free fatty acids or albuminous matters, readily form a milky emulsion with weak alkaline solutions. The cloth to be dyed is steeped in the oily emulsion, wrung out, and dried in a warm stove; this process is repeated six or eight times, and the cloth is finally washed in weak alkali to remove from it all the oil not intimately united to the fibre. The result of this treatment, which is the most delicate and important in the Turkey-red process, is that the cloth becomes impregnated with a fatty matter, which, by the contact of alkalies and heated air, has undergone some change from its original state, which is usually called an oxidation, but the nature of which is really unknown. The cloth now possesses a power of attraction for mordants and coloring matters greatly superior to untreated cloth; and, further, its physical condition is changed so that colors upon it are more transparent and more vivid than upon ordinary cotton. The cloth in this state is ready for mordanting, which is done by passing it through a bath of alum, partly neutralized with carbonate of soda or by chalk, or in a bath of acetate of alumina, the object being to obtain a regular deposition of the albuminous base upon the fibre; the excess of mordant is carefully washed away from the cloth, which is now ready for *D.* The *D.* is accomplished in the ordinary way, by keeping the cloth in continual motion in a vessel containing heated water and the dye-stuff, which may be madder, garancin, or artificial alizarin. It is a very general practice to add a quantity of ox-blood to the water used in *D.* Turkey red. What purpose this fulfils is not known; its coloring matter cannot be supposed to be of any use; its albuminous constituents may have some useful action, but this seems very doubtful; probably its addition is quite superfluous, and is retained from older times, when *D.* was less understood than at present. When the *D.* is completed the color is a full and deep but dull red, which requires brightening. The brightening operations consist in removing brownish matters from the dye by boiling in soap and alkalies. To give a still more brilliant color, the goods are boiled for several hours in a closed copper boiler with a mixture of salt of tin with the soap used in the last process of brightening, — occasionally under a pressure greater than that of the atmosphere, in order to obtain a temperature some degrees higher than 212° F. In many processes of Turkey red *D.*, the cloth is treated with decoction of gall-nuts, or with sumach, after the preparation with oil and before the mordanting; this enables it more easily to absorb and fix the aluminous mordant, but it is not essential, and is most generally omitted. No allusion has been made to a number of excrementitious and other animal matters, which the old dyers used in the oiling process, such as sheep-dung, cow-dung, ox-bile, etc.; they can be dispensed with, and were employed probably from caprice and ignorance.

*Barwood red.* — An imitation of Turkey red is obtained from barwood; it is much inferior both in beauty and stability to the real color, but the ease with which it can be dyed, and the less costly nature of the materials employed, enable it to be sold at a much lower price, and for some purposes it is largely used. Barwood is one of the red dye-stuffs of which the coloring matter is very slightly soluble in water; it is used in a state of fine powder. The cotton to be dyed is impregnated with a tin mordant by any of the means known to dyers, and then boiled with the dye-stuff; the coloring matter as it dissolves is fixed by the mordant, and the process is continued until the required shade is obtained. This wood, and a similar material called camwood, are also employed in woollen dyeing to give brownish reds, and to dye a "bottom" or foundation for indigo blue colors, by which some economy in indigo is effected, and a peculiar bloom on the blue is produced. — The class of woods

represented by Brazil wood do not yield good reds upon cotton.

**Blue Colors.** The most important of the blue coloring matters is indigo. This may be said indeed to be the most important of all coloring matters, both as regards the large quantity and monetary value of what is produced and sold, and the permanence and solidity of the dyed colors which it yields. The indigo dye is a manufactured article, prepared in the place of growth of the plant which produces it. The indigo plant could itself be used for *D.*, but from 200 to 250 lbs. of it would be required to produce the effect of a single pound of the prepared indigo. In countries possessing a temperate climate, the species *Isatis tinctoria*, or woad, has been cultivated, and has been used from time immemorial for *D.* blue. Its comparative poverty in coloring matter has caused it long since to be disused by dyers as a source of color; it is, however, employed by them in the preparation of their indigo vats, but rather as a convenient material to induce fermentation than as a dye. Indigo is distinguished from nearly all other coloring matters by its complete insolubility *per se* in water and other ordinary solvents. It dissolves to a very slight extent in heated aniline, petroleum, and acetic acid, which upon cooling reprecipitate it; the only real solvent for it is anhydrous acetic acid mixed with a little sulphuric acid, from which water precipitates it unchanged, but this solvent is inapplicable in *D.* But solubility is an essential condition for *D.*, and means have been found to obtain satisfactory solutions of indigo by circuitous methods which involve the temporary destruction of its blue color and a change in its chemical composition. By various deoxidizing agents, indigo blue can be changed into a white substance, indigo white, which dissolves with facility in all alkaline liquids, forming a colorless or slightly yellow solution. On exposure to the air or other sources of oxygen the solution yields the insoluble blue indigo, and permanently dyes any fibre which has been saturated with it. This is the only case in which such a method of *D.* is applicable, and on that account it possesses much interest. We shall now proceed to describe some of the practical methods in use for indigo *D.*

**Fermentation process.** The oldest of these, and one naturally suggested by the method employed in preparing the dye-stuff, is the process of fermentation in contact with lime, or sometimes soda or potash. During this process, gaseous or liquid substances are formed, which have the power of reducing indigo from the blue to the white state, and fitting it for *D.* This ancient method has not been superseded, being employed at the present day for nearly all woollen goods dyed with indigo, the consumption of which is greater for woollen than for all other kinds of cloth.

**The woad vat.** To a course of lectures upon *D.*, recently delivered by Mr. Jarnain before the Society of Arts of England, we are indebted for the substance of the following account of the woad vat used by the Yorkshire dyers. The materials employed are indigo, woad, madder, bran, and lime. For this process, as for every other in which it is employed, the indigo must be reduced to the finest possible powder. It is generally ground mixed with water, in closed revolving cast-iron cylinders containing iron rollers or balls, for several days, or until the slime or pulp formed contains no visible particles of the dye-stuff. The proportions of materials employed are:—

Lincolnshire woad.....	5 cwt.
Wheaten bran.....	18 lb.
Slaked lime in dry powder.....	22 "
Madder.....	21 "
Indigo.....	24 "

The woad is first placed in the *D.*-vat nearly filled with water, which is heated to between 140° and 150° F.; after some hours (required to soften the woad), the bran, madder, and indigo are added, and half of the whole quantity of lime. In a few hours, if all is right, signs of commotion produced by fermentation will be visible, the liquid will become greenish, and a blue scum will be visible on the surface; a piece of wool is put in as a test, and if in a short time it becomes dyed blue the process is proceeding well; a little more lime is added, but at intervals, so as not to check the progressing fermentation, and, if it should become necessary the vat is heated up by steam to its original temperature, on the third day the vat should be ready for *D.* Such a vat as this requires skilful management to control the fermentation; without lime the reduced indigo would not be dissolved; with too much lime the fermentation would be stopped. The woad acts as an easily fermentable matter, and furnishes a portion of blue color; the bran also no doubt is useful, on account of the ease with which it begins and promotes fermentation; the madder is probably of no use at all, its employment being still continued from an old unfounded notion that it gives some of its red coloring matter to the indigo-dyed goods, for the small amount of saccharine matter present in 2½ lbs. of madder cannot be held of any importance in the presence of 5 cwt. of woad. A woad vat, when ready for *D.*, consists of a certain depth of a tolerably clear solution of white indigo in lime, and a somewhat voluminous semi-solid mass at the bottom, consisting of the bulk of the woad, the excess of the lime, the insoluble part of the madder, and the impurities always present in indigo. To keep

the cloth to be dyed from contact with the muddy bottoms, an iron hoop, of the internal diameter of the vat, covered with a network of open meshes, is lowered into it and secured at a safe distance from the bottom. The pieces to be dyed, after being well cleansed, are placed in the liquor, and kept in constant movement to insure full access of the color to all parts. The time required to dye, varying from 20 minutes to two hours, will depend upon the fineness and weight of the cloth, and upon the depth of color required; if the goods require it, they are dyed a second time. In moving the pieces about, they must not be brought above the surface of the liquid, for the oxygen of the air would restore the dissolved white indigo to its blue insoluble state. When the pieces are found to be sufficiently impregnated with the dye, they are withdrawn from the vat; at the moment of leaving the *D.* liquor they are seen to be of a yellowish color, which almost instantly changes into a bright green, then darker green, and finally becomes blue through the absorption of oxygen by the white indigo. Loose wool or yarn is dyed by enclosing it in an open and movable network bag. The vat above described can of course dye only a limited quantity of material, becoming after every operation poorer in indigo; but it is not necessary to reset a vat. The strength of its contents is kept up by constant additions of indigo, lime, and bran, no more woad is added, the quantity used at first being sufficient for about its own weight of indigo. This vat is called *icarn* vat, being made and worked at a temperature considerably above that of the air,—a condition held necessary for *D.* wool and some kinds of heavy cotton goods. For ordinary cotton *D.* the vat is used cold or at the ordinary temperature of the air, and is prepared in a quite different manner.

**Prussian blue.** The simplest method of employing it consists in first impregnating the material to be dyed with peroxide of iron, and then passing it into a solution of yellow prussiate of potash acidified slightly with sulphuric acid. Prussian blue upon silks is thus dyed. The most convenient way of obtaining a deposit of the oxide of iron consists in soaking the silk in a somewhat strong solution of the ordinary dyers' nitrate of iron; in the course of two or three hours a certain quantity of the oxide is found to be intimately combined with the silk; the excess of the nitrate is then washed away, and the silk worked in the acidified prussiate bath, when it immediately assumes a light azure shade; by repeating the treatment several times any depth of color may be obtained.—Calico can be dyed in the same way, but both for that and for silk it is usual to add to the iron solution a small quantity of salt of tin, which is useful in giving a purplish tone to the blue and preventing the production of a disagreeable greenish tinge.—A deep color cannot in this way be satisfactorily given to woollen, for which a treatment is adopted depending upon the decomposition of the prussiate by means of heat and acids. For *D.*, say 110 lbs. of merino, the following proportions and methods may be used. Dissolve 9 lbs. of yellow prussiate of potash in hot water, and add the solution to the required quantity of water; then add 14 lbs. sulphuric acid, 6 lbs. sal-ammoniac, and about 6 oz. of crystals of protochloride of tin; the merino is placed in the mixture, and the temperature of the dye-bath gradually raised to the boiling point in five hours. The blue gradually formed on the cloth requires brightening in a fresh bath consisting of alum, persalt of tin, and cream of tartar, heated to nearly the boiling point. Red prussiate of potash is used in nearly the same way to dye dark Prussian blues upon wool, but as it is more easily decomposed than the yellow prussiate a weaker acid-bath suffices. These blues are frequently finished off with logwood to give them a deeper tone.

**Aniline blues.** There are several artificial blue dyes made from aniline and similar bodies which yield very brilliant colors on wool and silk. They can be easily applied, the goods simply requiring to be worked in their aqueous solution until they have acquired a sufficiently dark linge. An artificial dye called Nicholson's blue is differently applied; it is dissolved in an alkaline liquid, and forms then a colorless or nearly colorless solution, with which the goods to be dyed are impregnated; they are then passed into dilute acids, which develop the blue color.

**Yellow Colors.** Yellow textiles, being less pleasing to the eye, and more readily soiled, are not nearly so much in use as those dyed with the two simple colors blue and red. The chief yellow dyes, besides fustic, are quercitron bark or its concentrated extract, flavine, Avignon or Persian berries, and the now almost disused weld. The general mordant for these is tin, sometimes with addition of alum. One or two illustrations will suffice to show the methods of using them.

**Fustic yellow.** Fustic is probably the most generally employed yellow dye-stuff for wool, it gives yellows inclined to orange. For light shades it is not necessary to mordant the wool; it is simply well cleansed, and then heated with fustic decoction and some cream of tartar. For darker shades the wool is boiled with solution of tin and tartar, washed, and then worked in the decoction of fustic.

**Picric acid yellow.** Picric acid, one of the artificial coloring matters, gives pure though not deep yellow shades upon silks and wool without the aid of a mordant, the cleansed material being dyed by working it in a warm solution of the acid.

**Chromate of lead yellow.** The yellow most commonly used

for cotton goods is obtained by the use of salts of lead and bichromate of potash. The method of obtaining this color differs somewhat from any previously described. The cotton, having been properly bleached, is impregnated with a salt of lead, usually by employing a solution of the acetate or subacetate of lead. The goods are next passed into a milk of lime solution, to which it is prudent to add some acetate of lead, in order to prevent the lime from dissolving the oxide of lead at first precipitated; the result of the lime treatment is that oxide of lead is evenly fixed upon the cotton; the excess of lime and lead is then well washed away, and the goods are passed into a solution of bichromate of potash, where they quickly acquire a bright and deep yellow color, owing to the formation of the well-known pigment chrome yellow. To facilitate the combination, the bichromate of potash is mixed with as much sulphuric acid as suffices to liberate the whole of its chromium as chromic acid. The yellow-dyed goods require no further treatment than a good washing, the color being quite fast. This yellow is, however, in very little demand, and in ninety-nine cases out of a hundred it is immediately converted into an orange, by passing it through boiling lime-water, which produces the basic chromate known as chrome orange, which has always been in demand for many articles of wear.

#### Compound Colors.

The so-called simple colors—red, blue, and yellow—having now been dealt with, it remains to treat of their combinations, and this may be done briefly, the processes employed being for the most part similar to those already described. The compound shades in Chevreul's chromatic nomenclature amount to nearly 15,000, and it is very probable that fully that number are produced by the dyers of the present day. For practical treatment, however, the compound colors can be reduced to comparatively few classes. Mixing the simple colors one and one we obtain three compound colors,—blue and yellow give green, blue and red give purple, yellow and red give orange; while there may be a normal green, purple, and orange, it is evident that all the varieties of these several colors will depend upon the proportions of their constituents. If the three simple colors be mixed together, say in equal proportions, we may get a normal brown, or even a black; but if in unequal proportions, an immense number of shades, varying from the imagined normal brown to gray and drab are produced. Although in many cases compound shades are produced by means of two or more simple colors, there are many natural as well as artificial dye-stuffs which yield them ready formed, and frequently purer than they can be otherwise obtained. Most of these will be found mentioned in the following brief notice of practical processes in use.

**Green Colors.**—*Lo-kao or Chinese green.* Until about the middle of the present century there was not an instance known of any green on textiles which was not composed of the two separate colors blue and yellow. About that time some green-dyed cottons, imported into France from China, attracted the attention of chemists, who were surprised that they could not separate the green into blue and yellow constituents. Inquiries showed that the Chinese employed a green coloring matter called *Lo-kao*, until then unknown in Europe. It was a costly dye-stuff, selling in China for its weight of silver. Some quantity of it was imported and used in silk-*D.* by the French; it was not, however, found altogether satisfactory, and has at length been quite abandoned for the aniline greens, which are in every respect preferable.

**Aniline green.** There are two or three kinds of artificial green dyes in use, of which that known as methyl-aniline green, applied in silk *D.*, is most in request. The so-called iodine green has also been somewhat extensively employed for all kinds of fabrics. These artificial and unstable materials are the only dye-stuffs for green possessed by the dyer, who is compelled to produce the color by means of blue and yellow elements. The arsenical mineral green and the oxide of chromium green may be just mentioned as of extremely limited employ. The blues used in *D.* green are indigo, Prussian blue, and the sulphate of indigo. The yellows are afforded by Persian berries, quercitron, fustic, or the yellow chromate of lead. The processes employed consist, for the most part, in the separate application of the blue and yellow; for example, in *D.* a fast green upon wool from indigo and any of the yellow dye-stuffs, the blue is first produced as previously described, and the proper mordant for the yellow is then applied to the cloth, which is afterwards placed in the yellow coloring matter; the two colors are so intimately mixed as to be indistinguishable even by high magnifying powers. It may be observed that the reception of the blue does not to any perceptible extent diminish the power of the cloth to combine with the yellow.

**Prussian green.** Prussian blue is employed as a basis in the same manner, only, not being capable of resisting chemical agents so well as indigo blue, it demands more care. The greens with Prussian blue bases are more lively than those made with indigo, but are not so fast. Sulphate of indigo is even less stable than Prussian blue. It is, however, cheap and easy of application, and gives rich colors. The greens made with chromate of lead are for the most part confined to cotton goods, and are not in much demand.

**Orange Colors.**—For cotton the chief orange dye is the

chromate of lead compound already described. For other materials the orange colors employed are nearly always composed of some of the red and yellow dyes mentioned in the preceding pages, such, for instance, as cochineal and fustic, which are applied in one bath, the same mordant serving for both.

**Arnatto orange.** A warm solution of arnatto in weak alkalies is used without mordant to impart to silk an agreeable orange shade. Its color is generally considered too yellow, but may be made redder by treatment with weak acids, or by previously giving the silk a light red foundation.

**Pieric acid orange.** Another orange on silk can be dyed by superimposing on a light pink a yellow obtained from pieric acid.

**Nitric acid orange.** Silk can also be permanently stained of a yellowish orange by means of moderately strong nitric acid, which must, however, be applied with great care, since a more than momentary contact would be very injurious to the strength of the fibre. This method of dyeing silk was formerly much used for handkerchiefs; by protecting certain parts from the acids with melted wax or similar resists, white designs were produced upon an orange ground.

**Purple Colors.**—The purple colors may be held to include all shades produced by an admixture of red and blue, such for example as lilac, violet, mauve, etc., and are of immense variety.

**Aniline purples.** Since their discovery aniline colors have been almost exclusively employed for dyeing silk and wool purple, yielding as they do shades which for lustre and purity surpass any obtainable from the older coloring matters, and possessing also a fair amount of stability. An aqueous solution of the dye without mordant is all that is required, and the goods when dyed need very little subsequent treatment. The aniline purples, violets, and mauves do not dye upon cotton without previous mordanting, and even then are so loose and unstable that they are only fitted for use where great fixity is not demanded, as for linings of clothing, etc. The most general mordant for the aniline purple colors on cotton consists of a tannate of tin obtained by first steeping the cotton in a solution of tannic acid, or in decoction of gall-nuts, sumach, or myrobalans, all of which contain tannic acid; after a few hours' contact a considerable quantity of tannic acid has become firmly attached to the cotton, and the goods, being now treated successively with stannate of soda and dilute sulphuric acid or in other ways, acquire a certain proportion of oxide of tin, and are prepared to receive the colors.

**Madder purple.** But the purple color *par excellence* upon cotton is obtained from madder or alizarin, the mordant being oxide of iron or a sub-salt of iron deposited on the fibre by treatment with the commercial pyrolignite of iron, commonly called iron liquor. This purple is remarkable for great permanency. It is very largely used in combination with black and white in the best kind of printed calicoes.

**Archil purple.** Archil and cudbear are sources of purple colors on wool and silk. The shades produced are rich and beautiful; they are not, however, very permanent, and have been nearly superseded by the aniline colors. Of the few instances that can be cited of stuffs dyed purple by the direct union of red and blue coloring matters, the violet or purple woollen cloth used for ecclesiastical purposes is an example. The indigo color is first fixed and cleansed, and then the cloth is dyed with cochineal and tin mordants in the way already described for dyeing scarlet. The purple thus obtained is a fast color, but is very costly, and on that account is not much worked.—The common shades of purple, violet, lilac, etc., upon wool are obtained from logwood with a mordant of alum and tartar; the red woods are sometimes employed in conjunction with logwood for these colors, which are "topped" with archil to give them more brilliancy.

The extensive range of colors, comprising all the shades of brown, bronze, chocolate, nut, wood, drab, and gray, which may be considered as compounded of the three elementary colors, some one of the three predominating, can only be briefly treated of in this article. Most of them are actually produced by the use of dye-stuffs yielding the three simple colors; but there are coloring matters like catechu, which themselves yield brown colors, and others, such as logwood, which may be held to contain two or more of the simple colors, the blue predominating. A few illustrations will show how these triply compounded colors are produced by the dyer.

**Brown Colors.**—*Brown brown on wool.* The wool is mordanted with alum and tartar in the usual way, and is then dyed in a mixture of fustic and madder or other equivalent red and yellow dye-stuffs; for fast colors a blue part can be communicated to it by the indigo vat. For a lower class of colors no indigo is used, but instead, a mixture of yellow wood (fustic or quercitron) with madder for the red, and logwood for the blue part; or again, the sulphate of indigo may be employed for the blue.

**Tan brown.** The wool is mordanted by boiling it for an hour with one per cent of its weight of bichromate of potash; it is then washed, and transferred to the dyeing vessel, with the following percentages of its weight of materials: madder, 3.2; fustic, 4.8; carwood, 2; barwood, 1.75; sumach, 2.1; with these materials it is boiled for two hours.

**Dark drab.** The weights required to dye 100 lbs. wool, pre-

viously mordanted with 1 lb. of bichromate of potash, are as follows: camwood, 6½ lbs.; sumach, 2 lbs.; madder, 2½ lbs.; fustic, 4 lbs.; logwood, 2½ lbs.; boil for one hour and a half, and afterwards, to darken the color, pass into water containing 1 lb. of sulphate of iron.

**Black Colors.** Black, from a dyer's point of view, is compounded of the three simple colors, red, yellow, and blue, in a state of concentration; but in reality the blue predominates in all good black colors, and gives them their density and at the same time their lustre. What is called a dead black, crape black, or jet black, is the nearest approach to a neutral black, but even this would be brownish if the blue did not predominate. It is often extremely difficult to obtain a black dye to suit a particular market. Of ten pieces appearing equally black to the uninitiated, an expert would, perhaps, pronounce one to be sooty, another purple, another red, another brown, another green, and so on. We should have to go back some years in the history of *D.* to find a time when black was actually dyed with the three elementary colors. In some processes blue from indigo was first applied, and then, upon an alum mordant, red and yellow from madder and weld respectively; such a color was unexceptionable for stability, but its great cost caused it to be disused. At the present day, logwood is the chief dyestuff for blacks upon wool or cotton, and gall-nuts and other astringents for silks. Aniline black, on account of obstacles to its application, cannot be said to have yet established itself in *D.* proper, though it is much and highly valued in calico-printing.

**Black dye upon silk.** Silk easily takes a black by treatment first with decoction of gall-nuts, and subsequently with a salt of iron. For blue-blacks the silk is usually first dyed with Prussian blue, and then with gall-nut black. Extract of chestnut-wood with an iron mordant gives a good black. In modern black silk *D.*, materials are heaped upon the fibre which are not necessary to its color, but which increase its weight in an extraordinary manner, so as not only to compensate for the loss of 25 per cent of natural gum in the silk, but even, in some cases, to double or treble the original weight. The silk is, of course, much injured by the accumulation of foreign matters upon it, the fibre becoming harsh and brittle, and soon showing the effects of wear. The chief substances used for weighting are lead salts, catechu, iron, and galls, with soap or fatty matter, to soften in some degree the harshness these occasion.

Fig. 143. — DYE-VAT.

**Black upon wool.** Upon woollen cloth of fine quality, the black is dyed upon a basis of indigo blue, and, from the use of wool for this color, such blacks are in England called "wooded blacks." The first process, therefore, in producing the best black is to dye the wool in the indigo vat of a tolerably deep shade of blue, and afterwards boil it in a mixture of logwood and sumach, treating it with sulphate of iron. The latter process being two or three times repeated, a very perfect and durable black is obtained, provided the indigo basis is sufficiently deep, and only a minimum quantity of logwood has been employed, say about one fourth the weight of the sumach.

**Common black.** Common blacks upon wool have no indigo in their composition, but are dyed chiefly with logwood and iron salts; the wool and logwood are heated together for some time, and then sulphate of iron is added to the dye-bath. In other blacks of somewhat better quality, the woollen is boiled

for some time with solution of iron, copper, and aluminium salts, together with tartar, and when the mordanting oxides have been fixed, the color is dyed up in logwood. The bichromate of potash mordant can also be used for the black dye, and the cloth can be "bottomed" with camwood or barwood; it is then dyed up with logwood, to which fustic or sumach may be added.

**Black upon cotton.** Almost the only ordinary black in cotton dyeing is obtained from logwood with iron mordant: sumach is sometimes used, and very rarely the black is dyed upon an indigo blue basis by means of sumach or galls and iron. As before stated, aniline black has not yet been practically applied in dyeing cotton. A common method is to first heat the goods for some hours with decoction of sumach, wash mordant in sulphate of iron, and then dye in logwood; another method consists in fixing an iron basis upon the cotton by the method given above, and *D.* in logwood, along with a portion of sumach or fustic, according to the shade required.

**Velvet dyeing.** The most important branch of black *D.* upon cotton goods is that employed for cotton velvets and velveteens, in which it is desired to produce a rich lustrous effect; the process is long, tedious, and uncertain, consisting of successive applications of sumach, sulphate or acetate of iron, sulphate of copper, logwood, and fustic, — the end chiefly aimed at being the production of a black with blush or violet bloom.

**Dye-Kettle,** in hat-making, the vat of dyeing liquid in which the crate of hats on their blocks is repeatedly dipped and aired to confer the requisite depth and gloss of color. It contains a solution of sulphate of iron, verdigris, and logwood, and is maintained at 180° F. — *E. H. Knight.*

**Dyestuffs,** a collective trade name for the coloring materials used in dyeing. See **DYEING.**

**Dye-Vat,** a beck, or tub (Fig. 143), in which goods in piece or otherwise are saturated with a dye or a mordant in solution.

**Dye-Woods,** barwood, Brazil-wood, Campeachy-wood, camwood, fustic, and other woods used by the dyer and stainer, usually cut and ground, to extract colors from.

**Dyke.** See **COAL** (and Fig. 85).

**Dynameter,** an instrument for ascertaining by a simple process the magnifying power of telescopes.

**Dynamics,** a science which has for its object the investigation of the laws and principles which govern the action of forces.

**Dynamite,** an explosive preparation, consisting of a mixture of 75 parts of nitro-glycerine incorporated with 25 parts of a silicious infusorial earth. Ignited in the open air, *D.* burns slowly, but it is readily exploded as nitro-glycerine itself by means of a detonating fuse; and, though not equal in bursting or breaking power to uncombined nitro-glycerine, on account of the absorption by its inert constituents of part of the heat developed by the exploding shock, it is greatly superior to gunpowder, instead of which, or gun-cotton, it is employed in blasting coal and stone, removing piles, felling trees, and clearing stumps from forest land. Confinement is not requisite for the explosion of *D.*, and it can be used in damp situations without to any great extent impairing its action. It explodes if heated in a closed brass case, also on sharp percussion, when placed between two metallic surfaces; it should not, therefore, be kept in hermetically sealed receptacles of metal or other very solid material. At a low temperature *D.* loses its tendency to explode by detonation. Another defect is its liability to part with a portion of its nitro-glycerine, especially when in contact with porous substances, such as the paper of cartridges and wrappers. — Another preparation consists of 20 to 25 parts of nitro-glycerine with 75 to 80 parts of finely pulverized burnt clay from glass-works; and in some explosives sold as *D.* a mixture of sawdust and chalk is substituted for silicious substances.

**Dynamometer,** a name applied to any instru-

ment or apparatus which measures energy exerted or work performed. Fig. 149 shows a *D.* con-

Fig 149. — DYNAMOMETER.

structed for trying the tenacity of a rod. It consists of a heavy iron frame, at one end of which is

a box containing a stout steel spring. A pointer connected with this spring moves over a graduated arc on the top of the box. On the frame are two movable blocks or slides, one of which is attached to the spring, while the other may be carried backward and forward by a screw and crank. The rod whose tenacity is to be tried is stretched between the two slides, and the crank is then slowly turned so as to pull upon the rod until it breaks. The force thus brought to bear upon the rod bends the spring; and the position of the pointer when the rod breaks shows how much force it took to break it.

## E

**Eagle**, the principal gold coin of the U. States, which is a legal tender for \$10. The eagle was authorized to be coined by act of April 2, 1792; weight, 270 grains; fineness, 916 $\frac{2}{3}$ . By act of June 28, 1834, the weight was changed to 258 grains, and the fineness to 899.225; and by act of Jan. 18, 1837, the fineness was again changed to 900. The half-eagle, the most common gold coin of the States, and the quarter-eagle, were authorized and modified by the same acts, and are of proportional value. The double-eagle, legal tender for \$20, was authorized to be coined by act of March 3, 1849; weight, 270 grains; fineness, 900. The total amount coined to close of fiscal year ended June 30, 1878, was: *Double-eagles*, \$861,001,780; *eagles*, \$53,832,710; *half-eagles*, \$70,101,495; *quarter-eagles*, \$26,933,600.

**Eagle Fire Insurance Co.**, located in New York City, organized in 1806. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$300,000; net surplus, \$507,411.68; total cap. and surplus, \$807,411.68. Risks in force, \$25,420,170; premiums, \$97,293.32; premiums received since the organization of the Co., \$5,379,226.46. Losses paid, \$2,687,379.16. Cash dividends paid to stockholders, \$3,506,308.

**Eagles' Feathers** have a commercial value from being used in millinery, and the large quills for making artists' hair-pencils, etc.

**Eagle-Stone**, a description of clay iron ore.

**Eagle-Wood**. See **ALOE-WOOD**.

**Earing**, a rope attached to the cringle or ring of a ship's sail, by which the sail is bent or reefed.

**Earnest**, the sum paid by the buyer of goods in order to bind the seller to the terms of the agreement. To constitute *E.*, the thing must be given as a token of ratification of the contract, and it should be expressly stated so by the giver. After *E.* given, and what may be its amount, the vendor cannot sell the goods to another without a default in the vendee, and, therefore, if the latter does not come and pay, and take the goods, the vendor ought to go and request him, and then, if he does not come, pay for the goods, and take them away in convenient time, the agreement is dissolved, and he is at liberty to sell them to any other person.

**Earnings**, wages gained for work or labor done; profit made.

**Ear-Pick**, a small instrument for cleansing the ear of the cerumen.

**Ear-Ring**, a jewel or ornament suspended from the ear by a gold or other ring passing through the lobe. The use of this kind of ornament, which constantly was of great value, and sometimes was made of large size, dates from the remotest historical antiquity, the earliest mention of ear-rings occurring in the book of Genesis. These ornaments, which never have fallen into disuse, and enjoy at the present time a very high degree of favor, appear to have always been worn in pairs, the two ornaments in all respects resembling each other.

**Ear-Shell**, a flattened, univalve species of *Haliotis*, much prized for the enamelled iridescence of its inner nacreous coating, which renders it useful for inlaying papier-mâché work, etc.

**Earth-Board**, the mould-board of a plough; that which turns over the furrow.

**Earth-Closet**, a night-stool in which a body of earth receives the deposits, or is dropped upon them to absorb the effluvia; the resultant being to be utilized as a fertilizer.

**Earthenware**, a term generally applied to all utensils composed of earthen materials. In reference to chemical constitution there are two kinds: *Porcelain*, consisting of a fusible earthy mixture, along with an infusible, which, when combined, are susceptible of becoming semi-vitrified and translucent in the kiln; and *Pottery*, an infusible mixture of earths, which is refractory in the kiln, and continues opaque. The latter comprehends several sub-species, which graduate imperceptibly into each other, as stoneware, earthenware proper, flintware, fayence, delftware, and ironstone china. See **PORCELAIN** and **POTTERY**.

**Earth-Nut**. See **PEANUT**.

**Earths**, the name given in chemistry to a group of metallic oxides. The principal earths are baryta, strontia, lime, magnesia, alumina, berylla or glucina, yttria, zirconia, and thoria. The first four are termed *alkaline earths*; the remainder, together with the oxides of the very rare metals erbium, terbium, norium, cerium, lanthanum, and didymium, constitute the *earths proper*. The term "earth" was very loosely applied by the older chemical and pharmaceutical writers, and the practice is still common among the vulgar at the present day. Thus, *absorbent E.* (chalk), *aluminous E.*, *argillaceous E.* (alumina), *bolus E.* (bole), *bone E.* (phosphate of lime), *Fuller's E.* (an absorbent clay), *heavy E.* (baryta), *Japan E.*, or *terra Japonica* (catechu), *sealed E.* (bole), etc., are names even now frequently encountered both in trade and in books.

**Earthwork**, an engineering term applied to cuttings, embankments, etc.

**Earthworm Oil**, a green medicinal oil obtained from the common species of *Lumbricus*, and used as a remedy for ear-ache.

**Ear-Trumpet**, an instrument for the relief of defective hearing. It is made of metal, — silver or gong-metal being considered the best, — and it is curved in form, one end being small enough to enter the ear, and the other bell-shaped, and expanding outwards like the mouth of a trumpet, whence it derives its name. It is curved (Fig. 150) in order to collect the rays of sound, and oblige them to converge by reflection on the membrane of the drum of the ear, like rays of light collected in a focus by means of a lens. The collection of the rays of sound causes them to act on the drum of the ear with greater power. There are many different kinds of *E.-T.* differing from each other in construction, but being all made on the same principle, —

Fig. 150.—**EAR-TRUMPET**. to collect and concentrate the rays of sound. Some are very small, such as the auricle and ear-cornet, and can be worn in the ear, or attached to the head by elastic springs; others are made of india-rubber, in the form of long tubes, with a bell-shaped opening at one end like the metal instruments. There are also artificial *membrana tympani*, or membranes of the drum of the ear, made of vulcanized india-rubber, which are introduced into the orifice at the end of a piece of silver wire, and are found extremely

useful in cases where deafness arises from perforation of the natural membrane.

**Easel**, a painter's wooden frame, or rest, with a movable ledge, on which the canvas is supported for painting (Fig. 151). An *Easel-picture* is a picture of small dimensions, such as render it portable.

Fig. 151. — EASEL.

of the earth, or Oriental countries generally, as regards Europe, are commonly called *The East*. — *East by North*, or *by South*, that point of the compass which lies  $11\frac{1}{2}^{\circ}$  to the N. or S., respectively, of the point due E. — *East-northeast*, *East-southeast* (E. N. E., E. S. E.), that point of the compass which lies  $22\frac{1}{2}^{\circ}$  to N. or S. of east, or midway between N. E. or S. E. respectively.

**Eastern Islands.** See MALAYAN ISLANDS.

**Eastern R.R.**, of Massachusetts, runs from Boston, Mass., to State line, N. H., 41.390 m.; branches, 76.596 m.; leased lines, 163.980. This Co., whose offices are in Boston, was chartered in 1836, and was completed from Boston to the N. H. State line in 1840. Its branches are from Salem to Marblehead, 4 m.; from Beverly to Gloucester, 17.35 m.; from Salisbury to Amesbury, 3.75 m.; from Revere to Lynn, 9.52 m.; from Peabody to Wakefield, 8.12 m.; from Salem to Lawrence, 19.66 m.; from Hamilton to Asbury, 1 m.; from Wenham to Essex, 5 m.; from Swampscot to Marblehead, 3.8 m.; Charlestown br., 1.09 m. The Co. leases the following lines: The Eastern R.R. of N. H., 15.90 m.; Newburyport City R.R., 2.80 m.; Portland, Saco, & Portsmouth R.R., 51 m.; Portsmouth & Dover R.R., 10.88 m.; Portsmouth, Great Falls & Conway R.R. 71.37 m.; Wolfeboro R.R., 12.03 m. *Financial statement:* Cap. stock, \$4,997,600; funded debt, \$13,587,021.99, consisting of mortgage funding certificates, issued 1876, \$13, 165,619.46, payable 1906, interest (May and Sept.)  $3\frac{1}{4}\%$  for first 3 years,  $4\%$  for next three, and  $6\%$  for ensuing years. Various securities exchangeable for certificates, interest having stopped since 1876, \$227,002.54; Essex R.R. 1st mortgage bonds extended (issued 1856, payable 1896), \$194,400, interest (May and Sept.)  $6\%$ . Net earnings for 1878, \$841,268.25.

**East India Company (The)**, the most celebrated commercial association either of ancient or modern times, was incorporated during the reign of Queen Elizabeth, 1600, and empowered to trade to countries to the eastward of the Cape of Good Hope, exclusive of all other persons. Properly speaking, the company were only merchants, sending out bullion, lead, quicksilver, woollens, hardware, and other goods to India; and bringing home calicoes, silks, diamonds, tea, porcelain, pepper, drugs, saltpetre, etc., from thence. Not merely with India, but with China and other parts of the East, the trade was monopolized by the company; and hence arose their great trade in China tea,

porcelain, and silk. By degrees, avarice and ambition led the company, or their agents in India, to take part in the quarrels among the native princes; this course gave them power and influence at the native courts, from whence arose the acquisition of sovereign powers over vast regions. India thus became valued by the company, not only as commercially profitable, but as affording to the friends and relations of the directors opportunities of making vast fortunes by political or military enterprises. Many and severe have been the contests between the advocates of free-trade with India and the friends of the "incorporated company"; but at length the long-supported monopoly of that powerful body was abolished by the British government in 1833; and by act of 1858 the whole of the company's powers were transferred to the Crown.

**East Indies** [Fr. *Les Indes-Orientales*], a collective term vaguely applied to Hindostan, Farther India, and the Malay archipelago. See INDIA (BRITISH), and MALAYAN ISLANDS.

**Easton and Amboy R.R.** runs from Easton, Pa., to Perth Amboy, N. J., 60 m. This Co., whose offices are in Philadelphia, was chartered in 1872. The road was opened in 1875 and was constructed by the Lehigh Valley R.R. Co., to extend their main line to the seaboard. Cap. stock, \$5,000,000; funded debt, first mortgage  $6\%$  bonds, \$5,000,000.

**East Pennsylvania R.R.** runs from Reading to Allentown, Pa., 36 m. This Co., whose offices are in Philadelphia, was chartered in 1857, and the road opened in 1859. It was leased in 1869 to the Phila. and Reading R.R. Co., for a term of 999 years, at a rent consisting of interest on bonds and  $6\%$  on capital stock. *Financial statement:* Cap. stock, \$1,709,550; funded debt, 1st mortgage,  $7\%$  30-year bonds, payable 1888, \$495,900. Profit and loss, \$161,654.61. In 1878, two dividends of  $3\%$  each were paid, amt. to \$110,033.

**East River** communicates with the Hudson in the Bay of New York, and is formed by the narrowing of Long Island Sound, which opens with a broad mouth at the eastern end into and receives a strong impulse from the tides in the Atlantic. This channel is so called in contradistinction to the North River (the Hudson). As the Sound contracts to the west of the broad expanse in front of New Haven, and forms what is called *East River*, the oceanic currents act with a force that increases with the diminishing width of the stream; and this causes higher tides here than at any other place around the island, arriving at New York about three quarters of an hour earlier than those by the Narrows. This current drives upward along the east shore of the Hudson many miles in advance of the other, on the west; and thus the Hudson has two tides, which hardly unite their action till they have passed Tappan and Haverstraw bays.

**East River Bridge.** See Appendix.

**East Tennessee, Virginia, and Georgia R.R.** runs from Bristol to Chattanooga, Tenn., 242 m.; Branch, Cleveland, Tenn., to Dalton, Ga., 30 m.; total 272 m. This Co., whose offices are in Knoxville, Tenn., was organized in 1869 by the consolidation of the East Tenn. and Virginia R.R., and East Tenn. and Georgia R.R. It also owns the Cincinnati, Cumberland Gap, and Charleston R.R., is interested in the Western N. Carolina and Rogersville and Jefferson R.R. It has also leased for 20 years from 1877 the Memphis and Charleston R.R. Cap. stock, \$1,967,074; funded debt, \$4,186,100.

**Easy**, not pressed for money; the money market is said to be *easy* when the rates of interest are low and money readily borrowed on personal securities. — *T. McElraith*.

**Easy-Chair**, a luxurious padded or cushioned arm-chair, adapted for ease or rest.

**Eatable**, anything that is fit or proper for food; any edible substance; that which is used for food.

**Eau**. This French word, like *water*, its English synonyme, is applied to numerous substances, differing in their composition, sensible properties, and uses, of which the following are a few useful examples: *E. douce*, fresh or river water; *E. de mer*, sea or salt water; *E. de fontaine*, *E. de source*, spring water; *E. de puits*, well or pump water; *E. de rivière*, river water; *E. de distillée*, distilled water; *E. de rose*, rose water; *E. de vie*, brandy; *E. de Hongrie*, Hungary water; *E. bénite*, holy water; *E. forte*, aquafortis; *E. de sacon*, soap-suds; *E. de senteur*, scented water, etc.

**Eau Athénienne**, for cleaning the head and removing scurf, is an alcoholic solution of potash-soap with some solution of potash and aromatic oil.

**Eau de botot**, a mouth-wash, is a mixture of tincture of cedar-wood, 500 grammes; tincture of myrrh and tincture of rhatany, of each 125 grammes; peppermint oil, 5 drops.

**Eau de Cologne** (Cologne Water), a perfume, so named from the city of Cologne, where its manuf. was first established by an Italian, Giovanni Maria Farina, born in 1685, and by other members of his family, some of whom made it according to a method due to one Paul Feurinis. In 1879 there were in Cologne 35 establishments for the preparation of the perfume, 28 of which were in the hands of persons bearing the name of Farina. *E. de C.* consists of a solution of various essential oils in strong alcohol. The purity and thorough blending of the ingredients are of the greatest importance in the process of manufacture. It was first manufactured by making a spirituous infusion of certain flowers, pot-herbs, drugs, and spices, and adding thereto, after distillation, definite quantities of several vegetable essences. *Imp. duty*, 50 per cent.

The best receipt for *E. de C.* is as follows: Take dried rosemary, thyme, sweet marjoram, wornwood, balm, and hyssop, 1 oz. each; cloves, cinnamon, angelica root, juniper-berries, anise, cummin, fennel, and caraway-seeds, fresh orange-peel, and oil of bergamot, 1 oz. each; cardamoms, lavender-flowers, and bruised nutmegs, each 2 oz.; the whole to be digested in 10 quarts of alcohol several days, and then distilled to dryness by water-bath. Purity of the ingredients, and freedom especially of the alcohol from fusel-oil, are essential to the perfection of the perfume.

**Eau de la Florida**, a colorless fluid with a greenish-yellow deposit consisting of sugar of lead, 50 parts; flowers of sulphur, 20 parts; distilled water, 1,000 parts.

**Eaux**, in perfumery, are solutions of the fragrant essential oils in spirit, as *eau de Cologne*, etc.; or they are distilled waters, largely charged with the odoriferous principle of plants, as *eau de rose* (*rose-water*), etc. — *Eaux*, of the liqueur-manufacturer, are aromatized spirits or cordials.

**Eaux Médicinales** are either simply watery solutions (*Hydrolés*), or distilled water (*Eaux distillées*); or they are vinous or alcoholic tinctures or solutions of essential oils, aromatics, or more active drugs. See CORDIALS, HAIR-DYES, PERFUMERY, SPIRITS, TINCTURES, WATERS, etc.

**Eaves**, the lowest tiles, slates, etc., of the roof

of a house, which usually project over the side walls and throw off the water.

**Ebauche** [Fr.], a rough draught or sketch.

**Ebauchoir** [Fr.], a large chisel used by statuary to rough-hew their work.

**Ebb**, the reflux or return of the tide after it has reached its full flood; *ebb tide* being the receding tide towards low water.

**Ebéniste** [Fr.], a cabinet-maker.

**Ebonite**. See VULCANITE.

**Ebony** [Fr. *èlène*; Ger. *Ebenholz*; It. *ebano*], a hard, durable, black-colored wood, obtained from different species of *Diospyros*, a large tree, found in tropical countries, especially in India, the Malayan Islands, etc. That which is considered to be of the best quality is the *D. ebenus*, a native of the Mauritius, Ceylon, and Madagascar; being jet-black, astringent, and of an acrid, pungent taste. Ebony, besides its other qualities, is susceptible of an elegant polish or lustre, and has always been held in high estimation; it is at present chiefly used for inlaying, for making rules and scales, as not being liable to warp, and for other purposes in turnery; but it is in less request now than formerly for cabinet-making, cheaper woods, dyed black, particularly that of the pear-tree, being commonly substituted for it.

**Ebullioscope**, an instrument for determining the strength of a liquid by ascertaining its boiling-point.

**Ebullition**, the state of boiling, or the agitation of a liquid arising from its rapid conversion into vapor by heat. *E.* occurs in different liquids at very different temperatures, such temperatures being called their *boiling-points*. Under the same circumstances the boiling-points are constant, and by observing them the chemist is often able to distinguish liquids which much resemble each other. The boiling-point of the same liquid may, however, vary considerably under different circumstances. The causes which induce variation are increased or diminished atmospheric pressure, the greater or less depth of the liquid, and the character of the containing vessel. Thus boiling water is colder by some degrees when the barometer is low, in bad weather, or at the top of a hill, than when the barometer is higher, in fine weather, or at the bottom of a valley or mine. There is a very simple and beautiful experiment, illustrative of the effect of diminished pressure in lowering the boiling-point of a liquid. A little water is made to boil for a few minutes in a flask or retort placed over a lamp until the air has been expelled, and the steam issues freely from the neck. A tightly fitting cork is then inserted, and the lamp at the same moment withdrawn. When the *E.* ceases, it may be renewed at pleasure for a considerable time by the affusion of cold water, which, by condensing the vapor within, occasions a partial vacuum. Liquids in general boil from 60° to 140° lower than their ordinary boiling-points when heated *in vacuo*. The table at top of next page furnishes very exact information respecting the effect of increasing pressure upon the boiling-point of water. — Boiling water contained in a deep vessel is hotter than that in a shallow one, on account of the greater resistance in the one case than the other to the escape of the steam. It is also found that fluids boil at a lower temperature and more quietly in vessels with rough and spicular surfaces than in those with smooth or polished ones. The boiling-point of water, as marked on the scale of the thermometer, is 212° Fahr., but in glass vessels, under common circumstances, it varies from 212.254° to 215.6°; whilst in perfectly pure

and smooth glass vessels water may be heated to 221° Fahr. without boiling. That the elevation of the boiling-point in this case is due to the nature of the surface, may be at once demonstrated by throwing into water, about to boil in a glass matrass, a little iron filings or coarsely powdered glass, when ebullition will commence with almost explosive violence, at the same time that the temperature of the fluid will sink about 2° Fahr.

Boiling-points of various Liquids at the ordinary Atmospheric Pressure.

Name of Substance.	Boiling-point.
Liquid carbonic acid.....	— 10.8° Fahr.
Liquid sulphurous acid.....	+ 17.6 "
Chloric ether.....	51.9 "
Aldehyde.....	69.4 "
Ether.....	94.8 "
Bisulphide of carbon.....	113.5 "
Bromide.....	145.4 "
Wood spirit.....	149.9 "
Alcohol (sp. gr. .815).....	173.1 "
Benzole.....	176.8 "
Dutch liquid.....	184.7 "
Acetic acid.....	243.1 "
Sulphur (melted).....	602. "
Mercury.....	662. "

**Eccentric**, a mechanical contrivance for taking an alternating rectilinear motion from a revolving shaft.

Fig. 152. — ECCENTRIC.

It consists of a circular disk or pulley fixed on a shaft or axis which does not pass through the centre of the disk. The first diagram in Fig. 152 represents a side-plan of an *E.*; *a a* the disk, the centre of which is at *b*; the inner circle is the shaft with its centre at *c*; *e e* is a section along the axis of the shaft *d*, and *a' a'* an edge-view. A hoop, *g f*, embraces the groove *a' a'*, allowing the disk to turn within it. As the *E.* revolves with the axis, the hoop is alternately raised and lowered, and with it the rod *l*, which is keyed into it at *h*. The extent of the rise and fall of the rod is equal to twice *c b*, the distance be-

tween the centres. The *E.* is of great use when a reciprocating motion is required to be given to a rod.

**Echantillon** [Fr.], a sample, pattern, or specimen.

**Echéance** [Fr.], a specified day for payment; the falling due of a bill of exchange, etc.

**Echeveau**, the French name for a skein, knot, or hank of thread or silk.

**Echevette**, a small hank; the  $\frac{1}{16}$  part of a large skein of cotton thread or yarn, and the  $\frac{1}{2}$  part of an ordinary skein of wool.

**Economy**, prudence and care in the management or distribution of materials, etc.

**Ecrevisse** [Fr.], a cray-fish.

**Ecuador** (*Republica del*), an independent state of S. America, traversed by the equator, from which it takes its name. It extends from lat. 1° 35' N. to 5° 50' S., and is about 800 m. long, being bounded N. by Colombia, E. by Brazil, S. by Peru, from which it is separated by the river Amazon, and W. by the Pacific Ocean. The following table gives the estimated area and population of each of the 10 prov. into which *E.* is divided, according to official returns of the year 1875:—

PROVINCES.	Area: Eng- lish sq. m.	Population.
Chimborazo.....	5,544	110,890
Los Rios.....	11,310	61,922
Esmeraldas.....	7,439	8,000
Guayas.....	11,502	87,427

Oriente.....	168,460	73,143
Pichincha.....	9,035	102,281
Indians, unsettled.....	.....	200,000
Total.....	248,372	1,066,137

Not included in the above statement are the Galapagos, or Tortoise Islands, with an area of 2,950 sq. m., but nearly deserted, which belong to *E.* The capital of *E.*, Quito, stands on the eastern slope of the W. branch of the Andes, 9,534 feet above sea-level, in lat. 0° 13' 27" S., lon. 78° 50' W., 150 m. from Guayaquil; estimated pop. 80,000. The other important cities are Guayaquil (see below), Tacunga (pop. 20,000), Cuenca (pop. 25,000), Riobamba (pop. 16,000), Ibarra (pop. 15,000), Ambato (pop. 10,000), Otavalo (pop. 8,000), Guaranda (pop. 8,000), Cotacachi (pop. 4,000). The settled population is composed of Spanish creoles of pure descent, meztisos, mulattoes, and negroes, the greater part of them being agriculturists, graziers, and growers of cocoa. These form about a half of the population. The other half are native Indians, of whom those that live among the mountains (Fig. 153) are mostly agriculturalists, cultivating their lands with much care, and making for themselves coarse stuffs of wool and cotton. The Indians who inhabit the eastern plains are in a much lower degree of civilization. They cultivate only small patches of ground, and apply themselves chiefly to hunting and fishing. Three fourths of the population dwell in the western or mountainous part of the State. With the exception of such rude forms of belief as still linger among the semi-civilized Indians, the only religion professed by the Ecuadorian population is the Roman Catholic; and nowhere in modern times have Jesuits and priests had it more their own way. The oath of a Protestant has no value in a court of justice. The main basis of the constitution of

E. dates from 1843, but several important modifications have been introduced at various periods. The executive is vested in a president, elected for the term of 4 years, while the legislative power is given to a congress of two houses, the first consisting of 18 senators, and the second of 30 deputies, both elected by universal suffrage. The congress has to assemble on the 15th September of every year at Quito, the capital and seat of the government, without being summoned by the government. The nomination of the president takes place, in an indirect manner, by 900 electors, returned by the people for the purpose. The electors appoint, together with the head of the executive, a vice-president, who, in certain cases, may be called upon by congress to succeed him before

volcanoes occur in this republic, one of which, Cotopaxi, is 18,875 feet high, and is remarkable for its symmetrical form, resembling a truncated cone. The highest peak in E is Chimborazo, which rises 21,424 feet above the level of the sea, and belongs to the western range. The culminating points of the Eastern Cordillera are Cayambé, 19,535 feet, and Antisana, 19,137 feet high. The chief rivers are the Amazon (here called the Marañón) and its tributaries, the Napo, Tigre, Pastaza, and Putumayo or Ica. The last of these forms the N. E. boundary of the republic. They flow in a S. E. direction, except the Marañón, which flows nearly eastward. They are navigable for steamboats in the lower part of their course. The Putumayo and Napo are said to be navigable for 500 m. or more. — *Climate.* E. presents a great variety of climate in its lofty mountains, elevated valleys, and low tracts called *tierras calientes*. The snow-line varies considerably in the different seasons of the year, as well as according to the form and situation of the individual mountain. Wagner found it in May on Cotacachi, 15,788 feet high; on Guagua-Pichincha in June, 15,741; on Mozo-Pichincha in May, 15,762; on Illiniza in Dec., 15,494; on Carahuirazo in Jan., 15,858; on Tungurahua in Feb., 15,613; and on El Altar in Feb., 15,854. The greatest difference, according to his observations, existed between the south side of Cotopaxi (15,279 feet) and the north side of Chimborazo (15,914). This elevation of the snow-line — so great when compared with its European position — of course renders possible the existence of vegetable and animal life at a correspondingly great height. While St. Bernard's, the highest point of permanent human habitation in Europe, is only 8,577 feet above the sea, most of the towns and villages of the central plateaux from Ibarra to Cuenca lie between 8,500 and 9,500 feet. Many of the huts of the cottagers are at a height of from 11,500 to 12,800; and the loftiest of these, at Canayaco, on the north side of Chimborazo, in 1° 28' S. lat., stands no less than 13,395 feet above the sea. The temperature of these upland districts is of course comparatively low. "At Quito," says Professor Orton, "it is never either spring, summer, or autumn, but each day is a combination of all three." The thermometric mean is 58° 8'; the range in the 24 hours about 10°; the annual maximum 70°, and the annual minimum 45°.

Fig. 153. — CIVILIZED INDIAN OF ECUADOR.

his term of office has come to an end. The vice-president also fills the functions of minister of the interior. The president exercises his functions through a cabinet of three ministers, who, together with himself and the vice-president, are responsible, individually and collectively, to the congress. There is no power of veto with the president, nor can he dissolve, shorten, or prorogue the sittings of congress. By the terms of the constitution, no citizen can enjoy titular or other distinctions, nor are hereditary rights or privileges of rank and race allowed to exist within the territory of the republic. The president, Don José de Veintemilla, elected president Sept. 8, 1876, was appointed dictator for an unlimited period, by a convention, July 10, 1878.

The surface of E. is mostly mountainous, except the plains called *Llanos* in the eastern part. The country is traversed by two Cordilleras of the Andes, many peaks of which, called *nevados*, rise above the limit of perpetual snow. About 16 active

almost every morning the woods are watered with the gentle showers of the *torocio*. During the verano the Cordilleras and *mesas* are visited by violent hail-storms, and winds of almost incredible force sweep across the wintry scene. In its relation to human health the climate of the upland region is interesting. Goitre is common; and it is found necessary to maintain three large hospitals for lepers. Tubercular disease of the lungs, on the contrary, is said to be completely unknown 8,000 feet above the sea, while it is one of the most frequent of diseases in the coast districts of Tropical America. — *Vegetable Productions.* In the low countries that flank the base of the Andes the banana, yuca, plantain, cacao, jatropha, which produces cassava and manioc, the cotton-tree, indigo, coffee, and the sugar-cane abound; beneath the elevation of 4,000 feet, the plants chiefly cultivated for food are the sweet potato, mandioc, yam, and banana, with rice, maize, and some legumes; but above 3,100 feet most of these become rare, and thrive only in particular situations. The sugar-cane, however, has been grown as far up as 7,500 feet. In some of the valleys are extensive plantations of sugar-cane, cotton, tobacco, and cacao. The valley of Guayaquil is particularly fertile; the soil is alluvial, and there are few spots even between the tropics which can vie with it in richness and variety of vegetation. It is covered with groves of every kind of tropical fruit, either wild or cultivated, as the pineapple, pomegranate, shaddock, orange, lime,

lemon, peach, apricot, cherimoyer, pulta, grandilla, tuna, and paca. In the same region are found the olive, pepper-plant, tomatas, and sweet potatoes, gum copal, copiba balsam, carana, dragon's blood, sarsaparilla, and vanilla. To these succeed, in the humid and shaded clefts on the slopes of the mountains, tree-ferns and cinchona, or Peruvian bark, the finest kind of which is obtained about 8 to 12 miles south of Loja among the mountains of Uritusinga, Villanaco, and Rumustana, where the trees that yield it grow in a soil resting on mica-slate and gneiss, at the moderate elevation of 5,756 to 7,673 feet above the level of the sea. Between the elevations of 6,000 and 9,000 feet is the region best suited for the European cereals. Within the cereal limits are found the oak, elm, ash, and beech. Higher up, the large forest-trees, except the pine, begin to disappear; and on the mountains of Quito the ekallonia mark the highest limit of trees at an elevation of 11,600 feet. The bejarías, the highest of shrubs, terminate at 13,400 feet, above which, in rich and beautiful verdure, rises the zone of the grasses. Above these, among the trachyte rocks, only lichens, lecidia, and the brightly colored, dust-like lepraria are met with; and to these succeed the regions of perpetual snow. — **Animals.** In some parts of the low country the air swarms with mosquitoes and other flies still more tormenting, while the ground teems with snakes, centipedes, and other reptiles. The banks of the great rivers are crowded with caimans, or alligators. Bats are exceedingly numerous, and of great size; the forests of the warmer regions abound with armadillos, monkeys, and cavi; and everywhere are found the jaguar, the puma, the ounce, the ocelot, and several varieties of the wild-cat. The peccari and deer are likewise common, as well as that singular animal the ant-eater. The characteristic animals of the Andes are the llama, the guanaco, the vicuña, and the paco or alpaca, some of which are trained as beasts of burden, while others, particularly the vicuñas, run wild among the mountains, where they are hunted by the Indians. Sheep and cattle are reared in great numbers, especially the former, in the valleys of the Andes, and on the declivities of the mountains. Horses, asses, and mules are reared in sufficient numbers to be articles of export. The chief of the birds is the condor, which is found all along the Andes southward as far as the Strait of Magellan, but nowhere to the north of the equator. The turkey, vulture, and gallinazo are frequently met with, together with many kinds of smaller birds. In some districts, particularly along the coasts, considerable quantities of beeswax are collected; and higher up there are spots in which the cochineal insect is reared. Along the rivers of the great plain turtles are numerous; and their fat, called *mantería* butter, forms a considerable article of trade. Fishing is carried on to some extent along the coasts, and a good deal of salt-fish is prepared. A murex is also found, which yields a juice used in dyeing purple. — **Minerals.** *E.* is less rich in minerals, especially in the precious metals, than any other of the S. American states. There are, indeed, several mines of gold and silver, but the yearly produce is inconsiderable. In some places are found lead and quicksilver, but the latter is found, as usual, in combination with sulphur, in the form of cinnabar. Near Azogue, 15 m. N. E. by E. of Cuenca, the ore is found in an immensely thick bed of quartzose sandstone, containing fossil wood and asphalt. Sulphur is prepared in considerable quantities; gold has been washed from the sands of some of the rivers; and salt is obtained from sea-water along the coast.

**Commerce.** The foreign commerce of *E.* is chiefly carried on at the port of Guayaquil, which, with the ports of Manta and San Lorenzo, is open for general importation and the exportation of national produce. The ports open for exportation only are Santa Elena, Callao, Bahía de Caracas, Loja, and Ibarra. Guayaquil is the only port of general deposit for re-exportation to foreign ports. The principal articles of export of this republic are cocoa, hides, cattle, tobacco, wool, straw hats, coffee, orchilla bark, india-rubber, and an inferior description of cotton. Cocoa is the leading staple, the quantity annually exported reaching over 15,000,000 pounds. The total value of the foreign trade of *E.* may be stated at \$4,000,000. The countries which participate in this trade are the U. States, Mexico, Guatemala, Chili, and Peru, in America; and England, Spain, France, and Hamburg, in Europe. The foreign commerce, however, is mainly with Great Britain, the total value of exports to that country in 1877 being \$728,955, and of the imports of British produce \$1,259,375. The chief exports to Great Britain consist of cocoa, Peruvian bark, and dyestuffs; of the imports of British produce, cotton goods, to the value of \$911,575. — The commerce between the U. States and *E.* is very limited, owing mainly to the want of direct communication, and to the fact that the two great staples of the latter country, cocoa and straw hats, find but little demand in this country, the former being of limited consumption, and the latter subject to a duty of 40 per cent. — **Communication.** Artificial means of communication are still for the most part in a very primitive condition, though few countries have so little reason to be content with their natural highways by land or water. Many of the roads, even between important centres of population, are mere mule-tracks, altogether impassable in bad weather, it may be for weeks or months at a time; while the violent torrents which have so frequently to

be crossed often present nothing better than more or less elaborate bridges of rope, similar to the *jhuler* or *zampur* of the Kashmirians. The simplest of these is the *taravita*, consisting of a single tight rope, with or without a travelling rope by which the passenger or his luggage may be hauled across; the most complex is the *chimba-chaca*, a rude prototype of the regular suspension bridge, constructed of 4 or 5 ropes of agave-root fibre, supporting transverse layers of bamboos. The best are hazardous to all except a practised foot, and they go out of repair in a few years. Since the middle of the century something has been done to improve this state of affairs; and a very great deal more has always been about to be done. The first carriage was introduced into Quito in 1859, and the owner had to pay a tax for his invention.

**Finances** have long been in a rotten condition, and trustworthy information is of difficult attainment. More, perhaps, than any other country of S. America, *E.* has been slow in the development of her resources and national industry. Frequent revolutions have paralyzed its trade, and prevented the regulation of its finances. The public revenue in the year 1877 was reported to have amounted to \$1,655,000, and the expenditure to \$2,400,000. About one half of the revenue is derived from customs duties on imports at the port of Guayaquil. In 1879 the liabilities of the republic amounted to \$16,370,000, made up of a foreign debt of \$9,120,000, contracted in England in 1855, and internal liabilities amounting to \$7,250,000. — A bank of issue and deposit, called the Bank of *E.*, with a capital of a million dollars, was established in 1868.

**Money, and Weights and Measures,** same as those of COLOMBIA. See COLOMBIA.

**Guayaquil,** the principal port of *E.*, is situate in lat. 2° 11' 21" S., lon. 79° 43' W., on the river of the same name, about 10 m. from the Isla Verde, and 14 m. from the Isla Puña, on the Gulf of Guayaquil, opposite to the mouth of the river. Ships bound to Guayaquil generally call at the Isla Puña, where expert pilots may be had, who carry them up to the town by night or by day, according to the state of the tides. There is a dry dock on the S. bank of the river where several ships of a superior construction have been built. The port is one of the best on the Pacific, but the town is unhealthy. Pop. 35,000.

**Eddas,** a name given in the West Indies to a species of *Colocasia*, the tubers of which are roasted and eaten like the potato; they are also called *cocos*.

**Edge-Tool,** a general name for the heavier description of cutting-tools. In trade the following are included under this head: axes, adzes, chisels, gonges, plane-bits, hoes, trowels, hatchets, choppers, mincing and cheese knives, tanners' and curriers' knives, saddlers' knives, ship-scrapers, drawing-knives, etc. Other cutting-tools come under the heads of cutlery, agricultural implements, etc. *E.-T.*, formerly imported from Sheffield, England, are now manufactured in such perfection in the U. States as to command a ready sale in all the European markets. The value of *E.-T.* exported in 1878 was \$911,095, of which England contributed \$228,850.

**Edging,** anything used for a border to garments, etc., as narrow laces, fringe, ribbon-edging, etc. — The ornamentation of book edges by color sprinkling, marbling, gilding, and coloring.

**Edging-Iron,** a semicircular spade for cutting turf.

**Edging-Shears,** a gardener's shears for trimming the edges of sod around walks or beds.

**Edible,** anything wholesome or nutritious; esculent, or fit for eating.

**Edifice,** a large structure, or stately building.

**Edinburgh,** the capital of Scotland. See GREAT BRITAIN.

**Edition,** the impression of a work; the publication or republication, as the first, second, or third issue, etc., of any book, newspaper, etc.

**Editor,** the chief literary superintendent of a newspaper, serial, or periodical; one who revises and prepares a book for publication.

**Editorial,** appertaining to an editor; the leading article of a newspaper.

**Eduction-Pipe,** the pipe from the exhaust passage of the cylinder to the condenser.

**Edulcoration,** the affusion of water on any

substance for the purpose of removing the portion soluble in that fluid. *E.* is usually performed by agitating or triturating the article with water, and removing the latter, after subsidence, by decantation or filtration. It is the method commonly adopted to purify precipitates and other powders which are insoluble in water. The washing-bottle is a most useful instrument for the *E.* of precipitates. In its simplest form, it is a bottle fitted with two bent glass tubes, one drawn to a fine point and reaching to the bottom of the bottle, the other only entering the cork a few inches. By blowing down the latter tube, the water is forced out of the former in a fine stream.

**Eel**, a peculiar description of fish resembling the snake in its external form, but having otherwise little similarity. There are different species, but the most common is the sharp-nosed eel (*Muraena anguilla*). Eels inhabit almost all our rivers, lakes, and ponds, and are in great esteem for the table. The best kind—the silver eel—is that found in the clearest waters.

**Eel River R.R.** runs from Logansport, Ind., to Butler, Ind., 93.84 m. This Co., whose offices are in Logansport, was organized in 1877 by the purchasing bondholders of the Detroit, Eel River, & Illinois R.R. Co. on the sale under foreclosure of that road. Cap. stock, \$2,712,500; net earnings for 1878, \$67,842.

**Effect**, the amount of work performed by a steam-engine or other machine.

**Effects**, goods or movable property; available funds.

**Effervescence**, a chemical ebullition or ferment in liquids, which is common in gaseous or aerated waters and wines.

**Effervescing Draughts**, pleasant gaseous drinks or sweetened beverages.

**Effervescing Powders** are of various kinds, usually put up in two papers, one containing an alkaline bicarbonate, and the other citric or tartaric acid. After dissolving and mixing the solutions, carbonic acid escapes with effervescence. These powders are useful refrigerants, and are gently laxative. Rochelle salts are often added to increase the laxative effect, constituting what are called Seidlitz powders.

**Effigy**, a portrait or likeness; the representation of the sovereign on coins.

**Effilé** [Fr.], a kind of trimming; fringed linen.

**Efflorescence**, the spontaneous conversion of a crystalline solid into a dry pulverulent form. Crystals which in a dry atmosphere lose their water of crystallization, and become crusted over with a mealy powder, are said to be *efflorescent*.

**Egg**, the ovum of domestic poultry, which is largely used as food by all nations, and forms a considerable article of commerce in most countries. Besides our home produce, considerable quantities of eggs are annually imported from the Dominion of Canada, in barrels containing from 60 to 75 dozen, and from 2 to 2½ bushels of oats in which they are packed. For the year 1878 the imports amounted to 672,643,788 eggs, valued at \$726,037, all coming from Canada, with the exception of 1,653,000 received from China, and 20,340 from Hong-kong. *Imp. free.*

**Choice.** The larger end of a new-laid egg feels cold when placed against the tongue. New-laid eggs appear semi-transparent when placed between the eye and a strong light, and have a small and perceptible division of the skin from the shell, which is filled with air. This mode of examination among the trade is called "candling." When they shake they are stale. The eggs of turkeys

and peahens are much esteemed for some purposes; those of ducks and geese are coarse and inferior. — Sound eggs will sink if put into a solution, consisting of 1 oz. of salt in 10 oz. of water; in the same solution indifferent ones will float, whilst bad or worthless ones will swim even in pure water.

**Preservation.** Eggs may be preserved for any length of time by excluding them from the air. One of the cleanest and easiest methods of doing this is to pack them, with the small end downwards, in clean dry salt, in barrels or tubs, and to place them in a cool and dry situation. We have eaten eggs thus preserved that were more than a twelvemonth old, and that had been for some months on shipboard in a tropical climate, and which yet retained all the peculiar sweetness of new-laid eggs. With a like intention, eggs are placed in vessels containing milk of lime or strong brine, or are rubbed over with butter, lard, or gum water, all of which act by excluding the air. Eggs for keeping should never be laid on their sides, and when kept in the air should be occasionally turned to prevent the yolk attaching itself to the side instead of floating in the albumen. Some persons place the eggs in a netting or on a sieve or colander, and immerse them for an instant in a caldron of boiling water before packing them away. The practice of packing eggs in damp straw, or anything else that can convey a flavor, should be carefully avoided. The shells of eggs are porous, and readily admit the passage of gaseous substances, especially of fetid odors. It is from inattention to this point that a large number of the eggs imported from the coast of France have a less delicate flavor than those of our poultry-yards. Damp chopped straw, as well as most other organic substances exposed to warmth and moisture, readily ferment or putrefy; and during fermentation a considerable increase of temperature takes place, as any one may readily perceive by examining the common hotbeds in our gardens, which are merely masses of organic matter in a state of decomposition. Eggs, as long as they retain the embryo of the future chick in a vital state, possess in themselves a certain degree of warmth, which tends materially to promote the decomposition of the substances they are packed in, particularly in the presence of moisture.

**Packing eggs for shipboard.** In the bottom of the box may be placed bran, cut hay, and sawdust. Tear up old newspapers to about 8 or 10 inches square. The paper should be about medium, — that is, not too stiff nor too soft. Place one of these pieces of paper on the hand, and on this an egg, on one end; close the lower hand so as to bring the paper up all round the egg; with the other hand crumple the loose corners and edges of the paper down over the other end of the egg; lay another piece of paper on the hand, on which place the same egg, but the other end up; bring up the new paper and crumple down as before. This gives a good cushion to both ends, and a fair one over the centre. Repeat this till you have six thicknesses of paper, reversing the egg each time, and always keeping it on the end. This gives you a ball about 3 to 3½ in. thick by 3½ to 4 in. long. Care should be taken not to press the paper too closely to the egg while covering. Place on one end in the box or basket; place alongside, and press them together close enough to prevent their becoming loose in the box, fillings at the ends and on top with crumpled paper.

**Egg-Basket**, a kind of wire-basket for standing eggs in to boil, and also to hold them when placed on the table.

**Egg-Beater**, a whip of wires or a set of wire loops rotated by gear while plunged in the eggs contained in a bowl.

**Egg-Cup**, a small cup of earthenware, glass, metal, etc., for holding an egg.

**Egg-Glass**, a small sand-glass, running about three minutes, for boiling eggs by.

**Egg-Ladle**, a kind of spoon for taking eggs from a saucepan.

**Egg-Plant** [*Fr. aubergine*], the *Solanum melongena*, an annual herbaceous plant of the same genus as the potato and nightshade, is a native of India and N. Africa. The fruit is a globose or egg-shaped berry about four inches in diameter, but the size varies much according to the quality of the soil and climate. It is cultivated for food in the U. States and various warm climates. It flourishes in New Jersey, but not so well in the more northern States of the Union. It is mostly used fried, after being cut in slices.

**Egg-Poacher**, a metal vessel with stands, to place eggs in a boiler for cooking.

**Egret, Egrette**, a tuft of feathers; the feathers of the little egret heron (*Herodias garzetta*) are much esteemed for ornament.

**Egypt**, a country at the N. E. extremity of Africa, bounded N. by the Mediterranean Sea, S. by Nubia, E. by Palestine, Arabia, and the Red Sea, and W. by the Great Desert. The territories under the rule of the sovereign of *E.*, including those on the Upper Nile and Central Africa, conquered in 1874-75, are vaguely estimated to embrace an area of 1,406,250 sq. m., and to be inhabited by a population of 16,952,000, of whom about one third are in *E.* proper. The following tabular statement gives an area and pop. of the various divisions of the kingdom, and its recent annexations, according to government estimates of the year 1875:—

DIVISION.	Area : sq. m.	Population.
Egypt proper.....	175,130	5,252,000
Nubia.....	431,210	1,000,000
Former King dom of Ethiopia.....	588,530	5,000,000
Darfur, and other annexed territories.....	211,380	5,700,000
Total.....	1,403,250	15,952,000

*E.* proper is divided from old into three great districts, namely, *Mus-el-Bahri*, or Lower *E.*; *El-Wustani*, or Middle *E.*; and *El-Said*, or Upper *E.*,—designations drawn from the course of the Nile, on which depends the existence of the country. These 3 geographical districts, subdivided into 15 administrative provinces, had, according to an enumeration made by the government in March, 1875, a rural pop. of 4,603,660, and an urban pop. of 648,340, dispersed over the 6 following towns: Cairo (the capital), pop. 349,883; Alexandria, 212,054; Damietta, 29,383; Tanta, 28,500; Rosetta, 15,002; and Suez, 13,498. At the census of 1872 there were in *E.* proper 79,696 foreigners. The foreign pop. consisted of 31,000 Greeks, 17,000 Frenchmen, 13,906 Italians, 6,300 Austrians, 6,000 Englishmen, 1,100 Germans, and 1,390 natives of other countries. The present sovereign of *E.* is the sixth ruler of the dynasty of Mehemet Ali, appointed governor of *E.* in 1806, who made himself, in 1811, absolute master of the country by force of arms. His position was recognized by Imperial Hatti-Shériff of Feb. 13, 1841, issued under the guarantee of the five great European Powers which established the hereditary succession to the throne of *E.*, under the same rules and regulations as those of the throne of Turkey. The title given to Mehemet Ali and his immediate successors was the Turkish one of *Vali*, or Viceroy; but this was changed by an Imperial firman of May 21, 1866, into the Persian-Arabic of *Khidiv-el-Misir*, or King of *E.*, and the ruler of *E.* has since

been known as the Khidiv, or, as more commonly called, Khedive. By the same firman of May 21, 1866, obtained on the condition of the sovereign of *E.* raising his annual tribute to the Sultan's civil list from \$1,880,000 to \$3,600,000, the succession to the throne of *E.* was made direct from father to son, instead of descending, after the Turkish law, to the eldest heir. By a last firman,

Fig. 154. — THE PYRAMIDS.

issued June 8, 1873, the Sultan granted to the Khedive the hitherto withheld rights of concluding treaties with foreign powers, and of maintaining armies, since which date the khedives have held the rank of absolute sovereigns. The administration of *E.* is carried on nominally by a counsel of state of four military and four civil dignitaries, but is actually entirely in the hands of the khedive, whose power is absolute, and subject to no limitation. Ismaïl I. consented, however, under pressure of financial difficulties, to appoint in Sept., 1878, a ministry after European models, and to deprive himself of a portion of his autocratic power; but soon, impatient of the restraint imposed on him, he dismissed his foreign ministers, and was then constrained by France and England to abdicate in favor of his son, Mohamed Tewfik, June, 1879.

The political advantages of *E.*, in situation, natural strength, and resources, can hardly be overrated. It lies in the very route of the trader between Europe and Asia, and that between Africa and the other two continents. It is the gate of Africa, and the fort which commands the way from Europe to the East Indies. The natural ports on the Red Sea and the Mediterranean, selected and improved by the wisdom of Alexander and the Ptolemies, whose enterprises have been eclipsed by those of M. de Lesseps in our own days, have always been enough for its commerce, which the great inland water-way of the Nile has greatly aided. The inhabited country, guarded by deserts and intersected in Lower *E.* by branches of the Nile and canals, in Upper *E.* closely hemmed in by the mountains on either side, is difficult to reach and to traverse; at the same time its extreme fertility makes it independent of supplies from other lands, and thus easier to defend. The ancient wealth and power of *E.* should occasion us no wonder, nor even that the country still prospers in spite of centuries of Turkish misrule. The general appearance of *E.* is remarkably uniform. The Delta is a level plain richly cultivated, and varied alone by the lofty dark-brown mounds of ancient cities, and the villages in groves of palm-trees, standing in mounds often if not always ancient. We sometimes see groves of palm-trees besides those around the villages, but other trees are, except in some parts, rare. In Upper *E.* the valley is in as rich a state of cultivation, but very narrow, and bounded by mountains of no great height, which hem it in. They form the edge of the desert on either side of the valley, which has been cut through a rocky table-land by the river. They rarely take the form of peaks. Sometimes they approach the river in bold promontories, and at others are divided by valleys with the beds of torrents which flow only at very long intervals. The bright green of the fields, the reddish brown or dull green of the great river, and the tender tints of the bare yellow rocks, beneath the deep blue sky, always form a beautiful view. In form the landscape varies little and is not remarkable; in color its qualities are always splendid, and under the general uniformity show continual variety. — *Climate.* The climate of *E.*, being remarkably equable, is healthy to those who can bear great heat, and who avoid the unwholesome tracts of the country, such as the northern coast, where there are extensive salt marshes. Upper *E.* is healthier than Lower *E.* The least healthy time of the year is the latter part of autumn,

when the inundated soil is drying. In the desert, at a very short distance from the cultivable land, the climate is uniformly dry and unvaryingly healthy. E., however, is unsuitable as a permanent residence to Europeans who do not greatly modify their mode of life, and it is almost impossible to rear European children there; but if they arrive after the age of ten or a little more they do not usually feel its ill effects. As a resort for invalids E. cannot be recommended without caution. Persons suffering from asthma and bronchitis are likely to gain benefit from a Nile-voyage, unless the season is unusually cold. The climate of the desert does not in all cases suit them, the small particles of sand which are inhaled increasing the irritation. The desert air is undoubtedly good for consumption, and a wise plan is to encamp near Cairo, or still better to find some kind of house within the limits of the desert; and there are ancient sepulchral grottoes at Thebes and other sites which afford excellent quarters for any one who will take the pains to build a court and a few rooms in front of them. A Nile-voyage cannot be so safely recommended. The climate on the river itself is more changeable than elsewhere, and often in winter far colder than is good for delicacy of the lungs. No one should visit E. in the winter without heavy as well as light clothing. The atmosphere is remarkably dry and clear, except on the sea-coast; and even the humidity which is the consequence of the spreading of the inundation is scarcely felt but by its rendering the heat more oppressive. Sometimes a white fog, very dense and cold, rises from the river in the morning, but it is of rare occurrence and short duration. The heat is extreme during a great part of the year, but it is chiefly felt when accompanied by the hot winds of spring, and the sultry calm of the season of the inundation. The winter is often comparatively severe in its cold, especially as the domestic architecture is intended to protect rather from heat than cold. The general height of the thermometer in the depth of winter in Lower E., in the afternoon and in the shade, is from  $50^{\circ}$  to  $60^{\circ}$ ; in the hottest season it is from  $90^{\circ}$  to  $100^{\circ}$ , and about  $10^{\circ}$  higher in the southern parts of Upper E. On the coast of the Mediterranean rain is frequent, but in other parts of E. very unusual. At Cairo there is generally one heavy storm in the winter, and a shower or two besides, the frequency of rain having increased since the growth of Ibrahim Pasha's plantations between the city and the river. At Thebes a storm occurs but once in about four years, and light rain almost as rarely. The wind most frequently blows from the N. W., N., or N. E., but particularly from the first direction. The proportionate prevalence of these winds to those from all the other quarters, in the year, is about 8 to 3; but to those from the S., S. E., and S. W., about 6 to 1. (Clot-Bey, *Aperçu Général sur l'Égypte*, l. p. 30.) The northerly winds are the famous Etesian winds of Herodotus, which enable boats constantly to ascend the Nile against its strong and rapid current, whereas in descending the river they depend on the force of the stream, the main-yard being lowered. These winds also cool the temperature during the summer months. The southerly winds are often very violent, and in the spring and summer, especially in April and May, hot sand-winds sometimes blow from the south, greatly raising the temperature, and causing especial suffering to Europeans. The famous Simoom, properly called Samoom, is a much more violent hot sand-wind, which is more usual in the desert than in the cultivated tracts, but in either occurring only at long intervals. It is a kind of hurricane, more painful to experience, and injurious in its effects. — *The Nile*. The chief natural feature of E. is the Nile, and the great phenomenon of the country the yearly inundation. After the junction in lat.  $15^{\circ} 34' N.$  and lon.  $32^{\circ} 39' 58'' E.$  of its two great confluent, called the White River and the Blue River, the Nile takes a direction generally N., but with almost innumerable windings. It receives in lat.  $17^{\circ} 45'$  the waters of the Tacazze; and from this point to its embouchure, a distance of about 1,350 m., it receives no affluent whatever, — a solitary instance in the hydrographic history of the world. In antiquity, the N. seems to have discharged its waters into the sea by 7 mouths; but it has now only two outlets, those of Rosetta and Damietta. The former, or most W., has a width of 1,900 ft., with a depth of about 5 ft. in the dry season. The Damietta mouth is only 900 ft. wide; but its depth averages between 7 and 8 ft. when the river is lowest. The greatest breadth of the Delta is about 85 m. from E. to W., the distance of its apex from the sea being rather more than 90 m. The water of the Nile differs considerably in appearance and purity at various seasons of the year. A little after midsummer it becomes very turbid, and not long afterwards it assumes a green color for more than a fortnight, owing to the quantity of vegetable matter which it brings down from its upper course. It then resumes its turbid character for the period of the rise, and retains it, though in

a less degree, for the remaining portion of the year, until the following mid-summer. The water is extremely sweet, particularly in its turbid state. A careful filtration destroys its peculiar flavor, and the best method is to allow it to settle in the porous jars manufactured in the country. It is very wholesome, except during the short period at which it is green. The turbid appearance, greatest during the rise and inundation, is owing to the presence of large quantities of earthy matter, which are annually deposited. The Nile shows the first signs of rising in E. about the time of the summer solstice. At Khartoum, where the White Nile and the Blue Nile join, the beginning of the increase is observed early in April. The slowness of the rise in the earlier stage causes this difference. Usually the regular increase does not begin in E. until some days after the summer solstice, and the inundation begins about two months after that solstice. The river attains its greatest height at, or not long after, the autumnal equinox, and then, falling more slowly than it had risen, sinks to its lowest point at the end of nine months, when it remains stationary for a few days, until it begins again to increase. The inundation continues rather longer than it naturally would do, because the waters are retained for some time upon the lands by closing the mouths of the canals. The river's banks being a little higher than the rest of the cultivable soil, the water is conveyed by canals or cuttings, and does not pour over the banks. The inundations vary considerably, and, by either failing or rising to too great a height, cause much damage and distress. The Nile rises about 40 feet at the First Cataract, about 36 at Thebes, about 25 at Cairo, and about 4 at the Rosetta and Damietta mouths during a good inundation. If the river do

Fig. 155. — SHADOOFS.

(1. Ancient, from Thebes. 2. Modern.)

not attain a greater height than 18 or 20 feet, the rise is scanty; if only 2 or 4 feet more, insufficient; if it attain to 24 feet, or a greater height not exceeding 27 feet, the inundation is good; but a higher rise must be characterized as a destructive flood. Sometimes the inundation has failed altogether; as for seven years (A.D. 457-464) in the reign of the Fatimite caliph El-Mustansir bi-Ah, when there was a seven-years' famine; and low inundations always cause dearths. Excessive inundations, on the other hand, produce, or at least foster, the plague and murrain; so that a variation of a few feet is productive of the most serious consequences. Although the water is abundantly charged with alluvium throughout the year, and especially during the inundation, the annual deposit by the river, except under extraordinary circumstances, is very much smaller than might be supposed. Various computations have been made as to the exact deposit left in a century on the land, but they have not usually differed above an inch. If, however, we compare the quantity of deposit on certain very ancient structures, of which we know the date, we shall find that the amount has materially differed in various places. Such differences are the natural results of irregularities in the river's course, of the strength or weakness of the current at particular places, of the nature of the country, and many other disturbing causes. The mean ordinary rate of the increase of the soil of Egypt has been calculated by M. Girard, in the *Deser de l'Égypte*, as "very nearly" 125 millimètres, or 4,960 English inches in a century. — *Agriculture*. The agriculture of the modern Egyptians differs little from that of the old inhabitants. In one respect it is the converse: the ancients excelled in the management of dikes and dams, and raised water only by the simplest methods; the moderns, while they have paid less attention to the great canals and the means by which they were regulated, have employed more ingenious methods of artificial irrigation. The deficiency of population has partly caused the decay of many of the canals and dams and dikes, and has at the same time necessitated the economizing of human labor, for which that of cattle has been in a great meas-

are substituted. Of the machines the most common is the shadoof (Fig. 155) which is employed for raising water, and is still of the same form as that used by the ancient Egyptians; but there are also two kinds of water-wheels. The more usual of these is that called the *sakiyeh*, which is composed of a horizontal wheel turned by a pair of cows or bulls, or by one, and connected with a vertical wheel which is on the same axis as another around which are earthen pots in which the water is raised and poured into a trough. The *taboot* is a similar machine, which differs from the *sakiyeh* principally in having a hollow wheel instead of the wheel with pots, in the jaunts or fellics of which the water is conveyed. Sometimes a *katweh* is employed, which is a bucket like that of the shadoof, having four cords by which two men dip it into the river or canal and raise the water. Steam-pumps are now largely used. — The culture of cotton was introduced by Mehemet Ali with a view to promote his manufacturing schemes, and the Turkish grandees have found it a source of temporary profit. During the American war the profit was at its height, but subsequently it declined. The necessity of constructing dams to exclude the Nile water from the cotton-growing fields has rendered the inundations destructive, and the speculation seems on the whole to have injured the welfare of E. The agricultural implements of the modern Egyptians are rude in construction, and similar to those anciently employed in the country. One of these, however, was not known to the earlier inhabitants. This is the *nirag*, a machine "in the form of a chair, which moves upon small iron wheels or thin circular plates, generally eleven, fixed to three thick axle-trees, four to the foremost, the same number to the hindmost, and three to the intermediate axle-tree. This machine is drawn in a circle by a pair of cows or bulls over the corn." It is employed to separate the grain of wheat, barley, etc., and to cut the straw, which is used for fodder. The ancient Egyptians generally cut the wheat near the ear. An Egyptian garden is a miniature E. It is intersected by numerous small channels which are filled by one or more water-wheels. By these channels the water is spread over the garden, divided by them into many square compartments, edged with ridges of earth. This system of course makes it very difficult to keep a garden in good order, and no great variety of flowers is cultivated. — Though Mehemet Ali was very desirous to encourage manufactures, he did not endeavor enough to apply modern science to the improvement of agriculture. Ibrahim Pasha, who succeeded him, always maintained that the country should be agricultural rather than manufacturing, and introduced important improvements during his father's government. This system has been steadily pursued by Ismail I. Before the time of Mehemet Ali a kind of feudal system prevailed, and much of the land was held by small proprietors under the protection of the great emeers. By the massacre of the Memlooks, the pasha destroyed feudalism, and by arbitrarily seizing almost all the landed property rendered private tenure of land a most rare condition. He allotted to those whom he thus unjustly dispossessed annual pensions for life, as the only compensation for an act of tyranny to which even the history of E. scarcely affords a parallel. Those whose lands were not confiscated yielded them up through fear, and buried their title-deeds, which are yet so concealed. A system of government in which the supreme authority overlooks such acts, and subordinate governors perpetrate them, in defiance of the Muslim code and Arab jurisprudence, demands the most thorough and searching reform. — *Vegetable products.* E. differs from most other countries in having neither woods nor forests. Besides the palm-groves, we rarely see even a grove of trees, except in Lower E. The largest common trees are acacias, sycamore fig trees, and mulberry-trees, all of which are frequently planted on each side of the great roads near Cairo; and the most beautiful trees are the date-tree and the banana. The weeping-willow, myrtle, elm, and cypress are found in the gardens and plantations; and the tamarisk is to be seen everywhere.

The most common of the fruits are dates of various kinds, which are sold half-ripe, ripe, dried, and pressed in their fresh moist state in mats or skins. Many different sorts are enumerated as known in E. The dependencies, however, and not E., produce the finest of these dates. The hotter and drier climates of the Oases and Lower Nubia best suit the date-palm; and the pressed dates of Sewah, the ancient Oasis of Jupiter Ammon, are among the most esteemed. The grape is a common fruit, but wine is not made from it on account of the prohibition of Mohammed. The Feiyoom is celebrated for its grapes, and chiefly supplies the market of Cairo. The most common grape is white, of which there is a small kind far superior to the ordinary sort. The black grapes are large, but comparatively tasteless. The vines are trailed on trellis-work, and form agreeable avenues in the gardens of Cairo; but little attention is paid to their culture, the common fault of Egyptian agriculture and gardening, due to the generosity of nature and the indolence of the inhabitants. The best-known fruits, besides dates and grapes, are figs, sycamore-figs, and pomegranates, apricots and peaches, oranges and citrons, lemons and limes, bananas, which are believed to be of the fruits of Paradise (being always in season), different kinds of melons (including some of aromatic flavor, and the refreshing watermelon),

mulberries, Indian figs or prickly pears, the fruit of the lotus, and olives. Many of these are excellent, especially the figs and melons. The trees and plants which produce most of them are chiefly confined to the gardens. The cactus, bearing the Indian fig, is extremely common, and forms the hedges of gardens and plantations. The vegetables, etc., are very common and of various kinds, so that we cannot wonder that the children of Israel longed for them in the desert. The principal are beans, peas, vetches, lentils (of which a pottage is made, which is the common food of the Nile boatmen), lupines, chick-peas, the loobyeh (*Dolichos lubia*), fenugreek, mallows, the bamieyeh (*Hibiscus esculentus*), spinach, purslain, meloo-kheeyeh (*Corchorus olitorius*), leeks, onions, garlic, celery, parsley, chicory, cress, radishes, carrots, turnips, colocasia, lettuce, cabbage, fennel, gourds and cucumbers (both of several kinds), the tomato, the egg-fruit or badiogán (black and white), caraway, coriander, cumia, aniseed, and red pepper. — The chief field-produce is wheat (which is more grown than any other kind of corn), barley, several sorts of millet, maize, rice, oats, clover, peas, the sugar-cane, roses, two species of the tobacco-plant, and cotton, now largely cultivated. The sugar-cane is extensively cultivated, and excellent sugar is manufactured from it. There are fields of roses in the Feiyoom, which supply the market with rose-water. The tobacco produced in E. is coarse and strong compared with that which is used by the middle and upper classes and imported from Syria and Turkey. That of Syria is considered the best. Of textile plants, the principal are hemp, cotton, and flax; and of plants used for dyeing, bastard saffron, madder, woad, and the indigo plant. The intoxicating hashesh, which some smoke in a kind of water-pipe formed of a cocoa-nut, two tubes, and a bowl, seldom used for any other narcotic, is not, as has been erroneously supposed, opium, but hemp. The effect is most baneful. The leaves of the hinni plant are used to impart a bright red color to the palms of the hands, the soles of the feet, and the nails of both hands and feet, of women and children, the hair of old ladies, and the tails of horses. Indigo is very extensively employed to dye the shirts of the natives of the poorer classes, and is, when very dark, the color of mourning; therefore, women at funerals, and generally after a death, smear themselves with it. Oil is extracted from the seeds of the cotton plant, hemp, colewort, the poppy, the castor-oil plant, sesame, and flax. The high coarse grass called halfeh (*Poa cynosuroides*) grows in great quantity in waste places and among ancient ruins. — Many kinds of reeds are found in E., though, if we compare the representations in the ancient tombs with what we see in the present day, it is evident that they were formerly much more common. The famous byblus, or papyrus, from which paper was manufactured, appears to be nearly, if not quite extinct, since Sir Gardner Wilkinson had not seen it (*Modern Egypt and Thebes*, I. 441). M. Delile, in his excellent account of the Egyptian flora, merely mentions it by name in his list as the *Cyperus papyrus*, called in Arabic *berdy*, and found at Damietta, but gives no figure of it. The lotus, greatly prized for its flowers by the ancient inhabitants, is still found in E., though it is not common. — *Animals.* The zoology of E. is not of remarkable interest, although it contains some very curious points. The absence of jungle and of forest, and the little cover thus afforded to beasts of prey, as well as other wild animals, partly cause this; and we observe few birds of beautiful plumage for the same reason. The most characteristic of the beasts is the camel, which is more at home in the dry climate of E. than elsewhere out of his native deserts. It has been remarked, however, that the camel, like his master the Arab, degenerates when removed into a city or a cultivated tract, that the former commonly becomes mangy, and the latter experiences a physical and moral degradation. The Egyptian camel is of the one-humped kind, which has been erroneously called the dromedary, whereas the dromedary is merely a swift camel standing in the same relation to the ordinary camel that our saddle-horse does to our cart-horse. Camel's flesh is for the most part eaten only by the peasants and the Arabs of the desert; by the Copts it is considered unlawful food. It is very remarkable that no representation of the camel has been found in the sculptures and paintings of the Egyptian monuments among the very numerous figures of the animals of E., both tame and wild, and of those brought from foreign lands as presents. It does not appear to have been introduced into other African countries until after the Christian era; but it was known to the Egyptians, although it is by no means certain that it was one of their domestic beasts. To modern E. the camel is very valuable, since the traffic with Syria, Arabia, Western Africa, and Ethiopia is to a great extent carried on by caravans. But the ancient Egyptians appear to have derived their wealth more from tributary presents than from commerce, to have allowed their land commerce to be much in the hands of foreign merchants, like those who brought Joseph into E., and to have left even their sea commerce partly at least to foreigners. The wild animals are tigers, hyenas, camels, antelopes, apes, dromedaries, horses, large asses, crocodiles, hippopotami, the chameleon, and a kind of rat called *lehnemon*. The birds are ostriches, eagles, hawks, pelicans, water-fowls of all kinds, and the ibis, which resembles a duck, and was deified by the ancient Egyptians, on account of its de-

stroying serpents and noxious insects. Among the reptiles is a serpent called the cerastes, or horned viper, the bite of which is fatal to those who have not the secret of guarding against it.

**Public Works and Manufactures.** The public works carried out in E. during the present reign would fill a long catalogue, without reckoning the SUEZ CANAL (q. v.). Railway communication has been established between Alexandria, Cairo, Ismaïlia, Suez, Damietta, the Felyoum, and Ayyout, the various lines covering over 1,200 miles. A Soodan railway, from Wâdee Halfeh to Hannek, and from near Dunkalah to Khartoum, involving costly and difficult engineering for a length of more than 1,000 miles, has been begun with the view of shortening the passage to India, and bringing the produce of the rich southern soil into easier connection with Cairo; these works are, however, at present at a standstill. The canal system has been greatly enlarged and improved, but a still better result is anticipated from the barrage of the Nile, a plan projected by M. Mougel and now about to be carried out for the Khedive by Mr. Fowler. In 1871 the work of building a breakwater to defend the new harbor at Alexandria from the seas caused by the constant southwest winds was begun. The outer breakwater extends above two miles across the mouth of the harbor, enclosing an area of 1,400 acres of calm water. The structure rises 7 feet above the highest sea-level, and is of a uniform width of 20 feet. Harbor works have also been constructed at Suez. At a cost of over \$900,000, fourteen fine lighthouses have been erected, seven on the Mediterranean and seven on the Red Sea. Telegraph lines (begun by the enterprise of Sall) have been sent throughout E., covering nearly 6,000 miles, and putting Alexandria into direct communication with Khartoum; and this branch of the public service is managed by English officials. Submarine telegraphs also bring Egypt into communication with Candia and thence with Constantinople and Otranto, and with Malta and thence with England, France, etc. The post-office was bought by the government in 1835, and under the management of an English post official has been greatly improved. In about 70 towns and villages offices have been established, and several mails a day are despatched from the chief places. The manufactures of E. have been in a declining state for several centuries. Mehemet Ali tried to promote them by establishing large manufactories of cotton, silk, and woolen goods, tarbooshes, etc., and, especially in Upper E., sugar-refineries. Ibrahim Pasha was much opposed to his father's policy, and in pursuance of his own views he laid out extensive plantations of olive and other trees, erected powerful steam-engines for the irrigation of his lands, and on all his estates endeavored to encourage agriculture. It cannot be doubted that he had lived the correctness of his conviction that E. is an agricultural, not a manufacturing country, would under his rule have been fully verified. Mehemet Ali introduced cotton and largely cultivated it; the Turkish grandees found that from it they could extract more gain than from other field-produce, and large tracts were speedily devoted to its culture. The necessity, however, of excluding the waters of the Nile has caused several destructive inundations; and so long as the cotton growth remained a monopoly of the pasha it was no means of enrichment to the producer. Now, however, that the monopoly is abolished the trade in cotton is greatly increasing, and this produce will undoubtedly become every year a more important item in the wealth of the country. The old restrictions upon agriculturists have been more or less done away; and the government, whilst not wholly abandoning Mehemet Ali's views on manufactures, is yet alive to the paramount importance of affording every encouragement to agriculture.

**Commerce.** The commerce of E. is very large, but consists to some extent of goods carried in transit, which, however, has greatly declined in recent years, owing to the opening of the Suez Canal. In the year 1873 the total value of imports, consisting chiefly of cotton, linen, and woolen manufactures, hardware, machinery, coal, etc., amounted to \$23,050,000; and the exports, which are chiefly cotton, cotton-seed, wheat, barley, corn, beans, and gums, amounted to \$80,500,000. To the entire foreign trade Great Britain contributes about 70 per cent, and the rest is divided between France, Austria, Italy, and Russia, in descending proportions. There is almost no direct trade between E. and the U. States.

The cotton crop in 1873 extended over about 950,000 feddans (= 950,000 acres, nearly), and produced 2,877,086 quintals (of 110 lbs.) of ginned staple, 2,150,000 ardebs (of 5 bushels) of seed, and 4,124,300 loads of cotton staks, all together reaching a total value of about \$65,000,000. The export of cotton to Great Britain for the same year amounted to 181,214,116 lbs., valued at \$31,279,630.

**Finances.** The revenue of E. is variously estimated at from \$40,000,000 to \$55,000,000 per annum. Mr. Stephen Cave, sent to E. by the British government in 1875 to assist the Khedive in reforming the finances of his country, reported the income for 1875 at \$53,445,350. According to Mr. Cave, this revenue was insufficient to meet both the cost of the general administration of the country, estimated at from 25 to 30 million dollars, and the charges of a debt variously reported to amount to from 430 to 455 million dollars. In order to prevent unavoidable insolvency, Mr. Cave recommended a conversion of the debt, to be effected with the assent

of the bondholders. The same recommendation was repeated by Mr. George J. Goschen and M. Joubert, representatives of the British and French bondholders of the Egyptian debt, who went to E. in the autumn of 1876 to confer with the Khedive on the finances of E. From the information furnished to them, they arrived at the conclusion that the annual revenue for 1876 and the following years would amount to \$54,610,000, and that a balance might be established with the expenditure, if the public liabilities of E. and the private debt of the Khedive were separated, and reduced by conversion. The plans submitted by Messrs. Goschen and Joubert were adopted Nov. 18, 1876, by the Khedive, who decreed that the "Unified Debt of E." should be reduced to \$236,000,000 by conversion, and be separated entirely from the "privileged debt" and other loans. The interest on the "unified debt" was fixed at seven per cent, of which one per cent was to be retained as a sinking fund during nine years, to provide for the extinction of revenue from the Moukabala tax, ceasing at the end of this term. The control, both of the debt of E. and of the general revenue and expenditure, was placed, by the stipulations agreed to by the Khedive in Nov. 1876, under the control of a financial commission, consisting chiefly of Europeans. A controller-general of revenue and a controller-general of the public debt and audit were appointed, with the fullest powers of supervision. The first report of the actual revenue of Egypt made by the controller-general was issued in April, 1878. It stated the total receipts of the government in the year 1877 to have been \$43,751,000, and it estimated the total receipts for the year 1878—being "a year following a bad Nile"—at no more than \$36,500,000. The same report notified that the service of the public debt for the year 1878 would require \$29,500,000, leaving only \$7,000,000 available to carry on the administration of the country. By the convention with Messrs. Goschen and Joubert, ratified by the Khedive November 18, 1878, there was instituted a Commission of the Public Debt. It is made a permanent institution, and the revenues of E. are pledged to the Unified Debt, to be paid direct to the Commission. According to a report of the Public Debt Commissioners, Signor P. Baravelle and Major E. Baring, the liabilities of E., placed under European control, amounted on the 8th of Sept., 1877, to \$391,419,100. Not included in this total was the personal debt of the Khedive, called that of the Daira Sanieh, which was returned at \$44,077,150, in an official report issued in August, 1878. To provide for the interest of this debt, the Khedive made over, at the same date, his private estates, estimated to embrace 432,000 acres, of the annual value of \$2,125,000, to the Commission of the Public Debt. Not secured by any stipulation on the part of the government is the floating debt of E., the exact amount of which is not known, but which is estimated to be over \$25,000,000.

**Money.** The standard unit of currency is the *kiras*, or piastre (= about 5 cents), which is coined in gold pieces of 5, 10, 20, 25, 50, 100 piastres; silver of 1, 2½, 5, 10, 20 piastres. Copper coins of 5, 10, 20 paras (or faddah, 40 to the piastre) and 1 piastre are also coined. The *kres*, or purse, of 400 piastres, is equal to about \$5 2s. 6d. The *khazneh*, or treasury, consists of 1,000 purses. Besides the regular Egyptian currency, European coins of all kinds are commonly employed in E., especially the English sovereign, the French napoleon, the Venetian sequin, the Spanish doubloon and dollar, the 5-franc piece, and the Constantinople coins.

**Weights and Measures.** The Egyptian measures are,—the *fitr*, or space measured by the extension of the thumb and first finger; the *shibr*, or span; and the *cabut* (of three kinds, = 22½, 25, and 26½ inches). The measure of land is the *faddan*, very nearly equal to the English acre, subdivided into 24 *keerats*, and each of these into 330 (formerly 333½) *kasabehs*, or rods, the *kasabeh* being a square measure with side of 22 *kabdehs*, each equalling 6½ inches. The *ardab* is equal to about 5 bushels, and is divided into 6 *seyryehs*, and each *weybeh* into 24 *rubas*.

The weights are these:—

- 64 *kamhaks* (or grains of wheat), or 48 *habbehs* (or grains of barley) = 1 dirhem (= 48 gr. Troy).
- 12 *dirhems* = 1 wukeeyeh or ounce (= about 575 gr.).
- 12 *wukeeyehs* = 1 ratl or pound (= 15-oz. 13 dr. avoird.).
- 2½ *ratls* = 1 wukkah or oke (= 2½ lb.).
- 36 *wukkaks* = 1 kantâr or cwt. (= 99 lb.).
- 24 *keerats* = 1 mithkâl or weight of a denâr (= 72 gr.).

The French metrical system has been established by Ismaïl I., but has not yet been generally adopted.

**Alexandria**, the principal seaport of E., on the coast of the Mediterranean, about 14 m. W.S.W. of the Canopic mouth of the Nile; the lighthouse being in lat. 31° 11' 43" N., long. 29° 51' 40" E. The light, which is fixed, is visible 20 m. in clear weather. The situation of this famous city was admirably chosen by its far-seeing founder, Alexander the Great. Until the discovery of the route to India by the Cape of Good Hope, E. formed the centre of the commerce between the eastern and western worlds; and Alexandria was placed in the most favorable position in E. for an emporium, being the only port on its northern coast where there is, at once, deep water and security for shipping throughout the year. The ports of Rosetta and Damietta, the former on the west and the latter

on the eastern arm of the Nile, are both difficult of entrance, each having a bar upon which there is always a dangerous surf. Ships bound for Alexandria avoid this serious inconvenience; and by means of an artificial navigation, stretching from the city to the western branch of the Nile, it has almost the same facilities for internal navigation that are enjoyed by the cities referred to. Under the Turks the city sank into insignificance, numbering only about 6,000 inhabitants. Soon after Mehemet Ali became ruler of E he turned his attention to the restoration of Alexandria. One of the most important works that he effected with this view was the opening of the Mahmoudieh Canal in 1820. This was accomplished at a cost of about \$1,500,000, and, for want of proper management, at a melancholy loss of human life. It is about 50 m. in length, with an average width of about 100 feet, and communicates with the Rosetta branch of the Nile at the village of Atfeh. Since Alexandria became the centre of the steam communication between Europe and India, and the principal station on the Overland Route, its progress has been rapid. It has now regular communication with England, Marseilles, Brindisi, Constantinople, etc. In 1856 a railroad line between Alexandria and Cairo was opened for traffic, and was shortly afterwards extended to Suez, and several extensions have since been made to the cotton districts of the Delta. The ancient city was situated a little more inland than the modern one, opposite to the small island of Pharos, on which was erected the lighthouse, so celebrated in antiquity. This island was, partly by artificial means and partly by natural causes, gradually joined to the land by a mound, and on this the modern town is principally built. The isthmus and island have now the form of a T, its head being N. E. and S. W. A square castle or tower, built on a small islet or rock, at the extremity of a mole projecting from the N. E. angle of the city, is still called the Pharos, and may, perhaps, occupy the site of the ancient lighthouse. On each side of this islet there is a port. That on the western or African side, called the Old Port, the *Eunostos* of the ancients, is by far the larger and better. It stretches from the town westwards to Marabout about 6 m., and is about  $1\frac{1}{2}$  m. in width. It is bounded on the N. partly by the W. tongue or angle of the island on which the city is partially built, at the extremity of which is the new lighthouse, and partly by rocks and sand-banks. It has three entrances. The first, or that nearest the city, having 17 feet water, is about  $1\frac{1}{2}$  m. S. W. from the lighthouse; but it is too narrow and difficult to be attempted by any one not thoroughly acquainted with the port. The eastern side of the second or middle entrance is marked by buoys which lie about  $2\frac{1}{2}$  m. S. W. from the lighthouse; it is about a quarter of a mile wide, and has, where shallowest, 27 feet water. The third or western entrance has its western boundary within about three eighths of a mile from the east end of Marabout Island; it is about half a mile wide, and has from 25 to 27 feet water in its shallowest places. This last is the best entrance. Ships, when in, may anchor close to the town in from 22 to 40 feet water, and there is good anchorage in deep water all along the shore. Foreigners were formerly excluded from this port; but this prohibition no longer exists, and it is now principally resorted to by the shipping frequenting the port. What is called the New (though it be really the oldest) or Asiatic harbor is on the eastern side of the town. A rock called the Diamond lies a little to the east of the Pharos tower; and ships entering the port ought to have this rock about a cable's length on the right. If they get much farther to the left they will come in contact with a shoal which stretches westward from the Pharillon, or little tower, on the east side of the port. The water immediately within the port S. W. from the Pharos is from 30 to 40 feet deep; but the space for anchorage is very limited, and is exposed to the northerly gales. Ordinary tides rise 2 feet; but during the overflow of the Nile the rise is 4 feet. Variation  $13^{\circ}$  west. — The general appearance of Alexandria is by no means striking; and from its situation its environs are sandy, flat, and sterile. The Frank quarter, on the other hand, presents the appearance of a European town, having handsome streets and squares, and excellent stores. Among the principal public buildings are the palace of the pasha, the naval arsenal, the naval and military hospitals, custom-house, bourse, two theatres, several mosques, churches, convents, etc. Few of the remains of the ancient city are now visible. Most of those that were to be seen a few years ago have since disappeared, and the celebrated Cleopatra's Needle itself is now to be seen in London, on the bank of the gloomy river Thames. The most striking of still standing ancient monuments is the column styled Pompey's Pillar. It stands on a mound of earth about 40 feet high, and has a height of 93 feet 9 inches. The shaft consists of a single piece of red granite, and is 73 feet long and 29 feet 8 inches in circumference. The capital is Corinthian, 9 feet high, and the base is a square of about 15 feet on each side. From an inscription it appears to have been erected in honor of the Emperor Diocletian, and it was formerly surmounted by a statue of that monarch. The climate of Alexandria is mild and salubrious. The heats of summer are modified by the N. W. winds from the sea, which prevail during nine months of the year, the thermometer seldom rising above  $85^{\circ}$  F. In winter a good deal of rain falls, and throughout the year the atmosphere is

generally moist, being saturated with a saline vapor from the sea. Pop. 212,064.

**Suez.** See SUEZ CANAL.

**Eidam**, a kind of Dutch cheese of a globular form, and weighing about  $3\frac{1}{2}$  lbs. It is imported in cases of one dozen.

**Eider-Down.** See DOWN.

**Eidograph**, an instrument for copying drawings.

**Eighteenmo**, the size of a book formed by folding a medium-size paper,  $18 \times 24$  inches, into 18 leaves or 36 pages, or a double medium paper,  $24 \times 36$  inches, into 36 leaves or 72 pages. The term is usually written 18mo.

**Ejoo Fibre, or Indian Hemp**, a strong horse-hair looking fibre, obtained in the Malayan Islands from the sago-palm, *Arenga saccharifera*. It is very durable and tenacious, and universally employed, in the countries where the tree is indigenous, for making cordage, for nets and seines, for the rigging of vessels, and for cables.

**Elaine.** See OLEINE.

**Elastic Bands**, belts, braces, gaiters, etc., made with threads of india-rubber, either naked or covered.

**Elastic Gums**, a common name given to those vegetable extracts, such as india-rubber and gutta-percha, which may be elongated by heat, etc.

**Elaterium**, a medicinal feculence deposited from the juice of the wild cucumber, *Momordica elaterium*. It is sold in thin cakes, and when pure has a pale gray or greenish color, floats on water, is easily pulverized by pressure, and forms with rectified spirits a rich, green-colored tincture. Larger doses than  $\frac{1}{4}$  gr. of pure E. are poisonous.

**Elder**, the *Sambucus nigra*, a large shrub or small tree, common in all parts of the U. States. The wood, which is remarkable for its hardness, is often used for carpenters' rules, weavers' shuttles, meat-skewers, etc. The light pith of the branches is used for electrical purposes. The recent flowers are regarded as diaphoretic and pectoral, and a distilled water (*E.-flower water: aqua sambuci*) is made of them. The inner bark is purgative and emetic, and is used in dropsy; the leaves are purgative. The juice of the fresh berries is made into wine (*E. wine*), and is largely used to make factitious port wine, and to adulterate the real wine. E. wine is extensively manufactured at Newark, N. J.

**Elecampane**, the aromatic bitter root of *Inula Helenium*, which is much used in some quarters, made into a sirup, for colds and coughs; from its pungency it was formerly in repute as a stomachic; a sweetmeat is also made from it.

**Electrical Machine**, an instrument for the excitation and collection of electricity. Fig. 156 represents the improved Ramsden machine. Between two wooden supports a circular glass plate, P, is suspended by an axis passing through the centre, and which is turned by means of a glass handle, M. The plate revolves between two sets of cushions or rubbers, F, of leather or of silk, one set above the axis and one below, which, by means of screws, can be pressed as tightly against the glass as may be desired. The plate also passes between two brass rods shaped like a horseshoe, and provided with a series of points in the sides opposite the glass: these rods are fixed to larger metallic cylinders, C, which are called the prime conductors. The latter are insulated by being supported on glass feet, and are connected with each other by a smaller rod, r. The action of the machine is founded on the excitation of electric-

ity by friction, and on the action of induction. By friction with the rubbers, the glass becomes positively, and the rubbers negatively electrified; but the rubbers communicate with the ground by means of a chain, and, consequently, as fast as the negative electricity is generated, its tension is reduced to zero by contact with the ground. The positive electricity of the glass acts then by induction on the conductor, attracting the negative electricity. This negative electricity collects in the points opposite to the glass. Here its tension or tendency to discharge becomes so high that it passes across the intervening space of air, and neutralizes the positive electricity on the glass. The conductors thus lose their negative electricity, and remain charged with positive electricity. Before use, the rubbers are coated either with powdered *Aurum musivum* (sulphuret of tin), or

rubbers are pieces of wash-leather or woollen cloth covered with the amalgam above described. Connected with the prime conductor are metallic points, nearly in contact with the surface of the glass, which serve to collect its *E*. The lower half of the plate is covered with flaps of oiled silk which confine the *E* until it is collected by the points of the prime conductor.

**Electric, Electrical,** exhibiting the effects of electricity when "excited" by friction; pertaining to, derived from, or produced by electricity. An *Electric* is a substance which may under ordinary circumstances be readily made to evince electrical properties by friction. Electrics do not transmit or conduct electricity; whilst, on the other hand, *anelectrics* are good transmitters or conductors of electrical action. The most perfect electrics are shell-lac, sulphur, amber, jet, resinous bodies, gums, gun-cotton, glass, silk, diamond, agate, and tourmaline; dry fur, hair, wood, feathers, and paper; turpentine and various oils; dry atmospheric air and other gases, steam of high elasticity, and ice at 0° F. The most perfect anelectrics or conductors are the metals, charcoal, and saline fluids.

**Electric Clock.** Electricity began to be used as a regulator of clocks about 1840. In strictness, an *E. C.* has no maintaining power — either weight or spring — of its own; it is a mere-skeleton, receiving impulse from another clock. It has a dial-face, hour and minute hands, wheels to give motion to these hands, from the arbor of a seconds-hand, and a small electro-magnet. There may be such a clock as this in every room of a large building, and all of them will show exactly the same time as the parent clock which supplies the motive-power. Wheatstone, Kain, Appold, Shepherd, Jones, Smyth, and other inventors have contrived beautiful means for producing and communicating this motion. In the parent clock of Shepherd's *E. C.* the pendulum, the going train, and the striking train have each their own distinct system of electro-magnets; the pendulum may continue to oscillate although the clock train is at rest. In these

Fig. 159. — ELECTRICAL MACHINE.

graphite, or amalgam. If the hand be brought near the conductor when charged, a spark follows, which is renewed as the machine is turned. In this case the positive electricity decomposes the neutral fluid of the body, attracting its negative electricity, and combining with it when the two have a sufficient tension. Thus, with each spark the conductor reverts to the neutral state, but becomes again electrified as the plate is turned. The *Plate machine*, which is now much used in this country, consists of a thick plate of glass mounted on a horizontal axis and turned by a crank. At each end there is a glass standard, the one surmounted by a brass ball called the *negative* conductor, the other by a long cylinder of brass with rounded ends, called the *prime* or *positive* conductor. From the standard of the negative conductor project two brass strips in the form of a clamp, which hold the rubbers against the glass plate. These

and in all other forms of *E. C.* each impulse of the parent clock is communicated to all the secondary clocks through a long wire; and thus it is that nearly all the railroad stations in England receive Greenwich time from a parent clock at the Observatory.

**Electricity,** one of the great forces of nature; also that department of physical science which embraces all that is known respecting this particular force. Many theories respecting the nature of *E* have been advanced for the purpose of explaining electrical phenomena. The theory of Dr. Franklin supposed the existence of a single homogeneous, imponderable fluid, of extreme tenuity and elasticity, in a state of equal distribution throughout the material world. This fluid is assumed to be repulsive of its own particles, but attractive of all other matter. When distributed in bodies, in quantities proportionate to their ca-

pacities or attraction for it, such bodies are said to be in their "natural state." When we increase or diminish the natural quantity of *E.* in any substance, excitation is the result, and the substance, if "overcharged," is said to be electrified "positively"; or, if "undercharged," "negatively." These theories, and all others based upon the assumption that *E.* is a form of matter, have been found to be inadequate for the elucidation of electrical phenomena. At the present day, however, two kinds of electric forces are recognized, and distinguished as *negative* and *positive*, but they are both assumed to be analogous in principle, and very generally assumed to be simply due to different analogous motions of matter. For a full exposition, however, the reader must refer to some of the especial works on the subject.

**Electric Light.** See LIGHT (ELECTRIC).

**Electric Telegraph.** See TELEGRAPH.

**Electro-Etching.** See ETCHING.

**Electro-Gilding.** See ELECTRO-METALLURGY.

**Electrolysis,** the chemical decomposition of a substance by means of electricity.

**Electro-Magnet,** a bar of soft iron which, under the influence of a voltaic current, becomes magnet; but this magnetism is only temporary, for the coercive force of perfectly soft iron is null,

Fig. 157. — ELECTRO-MAGNET.

and the two magnetic fluids neutralize each other as soon as the current ceases to pass through the wire. An *E.-M.* has the horseshoe form (Fig. 157), and a copper wire, covered with silk or cotton, is rolled several times round them on the two branches, so as to form two bobbins, A and B. In order that the two ends of the horseshoe may be of the opposite polarity, the winding on the two limbs, A and B, must be such that if the horseshoe were straightened out, it would be in the same direction. The power of the *E.-M.* is enormously greater than that of any permanent magnet. A permanent magnet, weighing 1 pound, has been made to carry 27; but Dr. Joule was able to construct a small *E.-M.* by arranging the coils to advantage, and proportioning the wire of the

core, and the thickness and length of the wire, which would carry 3,500 times its own weight. *E.-M.*, instead of being made in one piece, are frequently constructed of two cylinders, jointly screwed to a stout piece of the same metal. Such is the *E.* in Morse's telegraph.

**Electro-Magnetism.** That part of the science of electricity and magnetism which treats of the production and properties of temporary magnetism by the passage of a current of electricity round a bar of soft iron. See MAGNETISM, and ELECTRO-MAGNET.

**Electro-Metallurgy, Electrotypy, Galvanoplasty, Electro-Gilding, Electro-Plating,** etc., a term including all processes in which electricity is applied to the working of metals. This wonderful and beautiful art may undoubtedly be traced to the early experiments of Crunkshank, Brugnatelli, and Davy; but it remained undeveloped until the late Professor Daniell devised in 1836 that particular form of battery which bears his name. A Daniell's cell consists, in its usual form, of a copper vessel containing a saturated solution of blue vitriol or sulphate of copper, in which is placed a porous cylinder containing dilute sulphuric acid; a rod of amalgamated zinc is immersed in the acid, and on the two metals being connected by means of a conductor, electrical action is immediately set up. The zinc, which forms the positive or generating element, is dissolved, with formation of sulphate of zinc; whilst the blue vitriol is reduced, and its copper deposited, in metallic form, upon the surface of the copper-containing vessel, which forms the negative or conducting element of the combination. Any one using this form of battery can hardly fail to observe that the copper which is thus deposited takes the exact shape of the surface on which it is thrown down, and indeed presents a faithful counterpart of even the slightest scratch or indentation. The first application of the art was made in France in 1839, and it became soon a fashionable amusement to copy coins, seals, and medals, by the new process. These copies in metals are termed *electrotypes*. The apparatus employed in the early days of the art, and which may still be conveniently used for small electrotypes, is

Fig. 158. — ELECTRO-METALLURGY.

a. An oval vessel of salt-glazed earthenware or wood nearly filled with a saturated solution of sulphate of copper.

b. A porous diaphragm, containing the cylinder or plate of zinc (c), and filled with dilute sulphuric acid.

d. A small bar of brass or copper fastened to the vessel by the binding screws (e, e), and supporting the plate of zinc (c), by the hook of copper wire (f), and the mould (g), by the hook (h).

i. A small shelf or partition to support crystals of sulphate of copper, to keep up the strength of the solution.

similar in principle to a single Daniell's cell. It usually consists (Fig. 158) of a glazed earthenware jar containing a solution of sulphate of copper, which is kept saturated by having crystals of the salt lodged on a perforated shelf, so that they dip just below the surface of the solution. A

smaller porous cylinder, containing very dilute sulphuric acid, in which a rod of amalgamated zinc is placed, stands in the jar, and is therefore surrounded by the solution of sulphate of copper. The object to be copied is attached by a copper wire to the zinc, and is immersed in the cupric solution. It thus forms the negative element of a galvanic couple, and a current of electricity passes from the zinc through the two liquids and the intervening porous partition to the object, and thence back to the zinc through the wire, thus completing the circuit. During this action, the zinc dissolves, and sulphate of zinc is formed; at the same time the copper solution is decomposed, and its copper deposited upon the metallic surface of the object to be coated, — the solution thus becoming weaker as it loses its copper, but having its strength renewed by consumption of fresh crystals of blue vitriol. To avoid the complete incrustation of the metal or other object, one side of it is coated with varnish or some other protective medium, so that the deposition of copper takes place only on such parts as are exposed. The deposit may be easily removed when sufficiently thick, and will be found to present an exact counterpart of the original, every raised line being represented by a corresponding depression. To obtain a fac-simile of the original it is therefore necessary to treat this matrix in the same way that the original was treated, and this second deposit will of course present the natural relief. Another method consists in taking a mould of the original coin in fusible metal, and then depositing copper upon this die, so as to obtain at once a direct copy of the original. Considerable extension was given to the process by the discov-

Fig. 159. — ELECTRO-METALLURGY.

- a. A constant battery cell.
- b. Decomposition cell: a cutical vessel made of wood or earthenware, and filled with a mixture of 1 part of dilute sulphuric acid (1 acid + 9 water), and 2 parts of saturated solution of sulphate of copper by measure.
- c, c. Moulds suspended to the brass rod (f), and connected with the zinc or positive element of the battery (a), by means of the screw (g).
- d. Pieces of sheet copper suspended on the brass rod (h), and connected with the zinc end of the battery, by means of the screw (v), employed to keep up the strength of the cupreous solution in the decomposition cell.

ery, apparently trivial, made in 1840, that an electro-deposit of metal could be formed upon almost any material if its surface was rendered a conductor of electricity by a thin coating of graphite or "black lead." Instead, therefore, of copying a coin in fusible metal, or indeed in any metallic medium, it is simply necessary to take a cast in plaster of Paris, wax, gutta-percha, or other convenient material, and then to coat the surface with finely powdered black-lead, applied with a camel-hair pencil. Medals in high relief, with much undercutting, or busts and statuettes, may be copied in electrotypes by first taking moulds in a mixture of glue and treacle, which forms an elastic composition capable of stretching sufficiently to permit of removal from the object, but afterwards regaining its original shape. — About the same time

another great step in the art was made by introducing the use of a separate battery. Daniell's cell, in consequence of its regular and constant action, is the favorite form of electric generator (Fig. 159). The copper cylinder of this arrangement is connected with a plate of copper placed in a trough containing a solution of sulphate of copper, to which a small quantity of free sulphuric acid is commonly added; whilst the zinc rod of the cell is connected with the objects on which the copper is to be deposited, and which are also suspended in the bath of cupric solution. The current enters the bath at the surface of the copper plate, which is the *anode* or positive pole of the combination, and passes through the solution to the suspended medals which constitute the *cathode* or negative pole. As fast as the copper is thrown down upon these objects, and the solution is therefore impoverished, a fresh supply is obtained by solution of the copper plate; this copper is consequently dissolved just as quickly as the electrotypes are produced, and no supply of crystals is needed, as in the case of the Daniell cell. The great advantage of using a separate battery is, that several objects may be coated at the same time, since it is only necessary to attach them to a metal rod in connection with the battery. Almost any form of galvanic arrangement may be employed by the metallurgist as a generator of electricity. But as the exciting liquid in a battery needs to be replenished from time to time, and as the zinc plates also wear out, its use is attended with more or less inconvenience in the workshop, and the electro-metallurgist has therefore turned his attention to other sources of electricity. In the machine constructed by Mr. Wilde, which has been largely employed by electro-metallurgists, a small magneto-electric apparatus, with permanent magnet, is employed to excite the electro-magnet of a much larger machine. The induced current of the second machine is stronger than that of the first in proportion as the electro-magnet is more powerful than the permanent magnet; this second current may then be used to excite another electro-magnet, and hence, by means of this principle of accumulation, currents of great energy may be obtained. The armatures in these machines are constructed on Siemens's principle, and consist of long bars of iron magnetized transversely, and having the wire wound longitudinally. During the rotation of the armature, so much heat is developed that special means are taken to prevent its accumulation. In another form of Wilde's machine, a vertical disk carrying a number of coils, each with its own core, is caused to rotate between two rings of magnets. Powerful machines, with multiple armatures of this kind, have been constructed, which are capable of depositing 4½ cwt. of copper every 24 hours. Thermo-electricity is another source of electromotive power of which the practical worker has availed himself. In 1843 a patent was taken out by Moses Poole for the use of a thermo-electric pile in place of a voltaic battery, but it is only within the last few years that such a source of electricity has been introduced into the workshop. The best-known form of thermopile is that devised by M. Clamond of Paris. One element is formed of tinned sheet-iron, and the other of an alloy composed of two parts of zinc to one of antimony. A large number of these pairs, insulated from each other, are arranged in circular piles around a central cavity, in which their junctions are heated by means of a Bunsen burner. The case with which such an apparatus can be manip-

ulated recommends this source of electricity to the electro-metallurgist.

Having procured a supply of electricity from one or other of these sources, the electro-metallurgist applies it either to the deposition of a metal upon a matrix or to the coating of one metal by another. Hence the art of *E.-M.* divides itself into two branches, one being called *electrotyping*, and the other being generally known as *electro-plating*. In the electrotype (see ELECTROTYPING) the reduced metal is separated from the mould on which it is deposited, and forms a distinct object of art; whilst in electro-plating the deposited metal forms an inseparable part of the plated object.

**Electro-plating.** The solution generally employed as electrolyte from which silver is separated is that of argento-cyanide of potassium. It should be borne in mind that the cyanide of potassium is a very dangerous poison. As in the deposition of copper, the apparatus used for plating may be the single cell, or the decomposition cell and battery. For plating small objects, a single cell of a Daniell's battery will afford ample decomposing power, but the battery arrangement is much more convenient, effective, and economical. On a large scale, electro-plating is carried out in oblong vats, occasionally holding from 200 to 250 gallons of solution. Silver plates connected with a powerful voltaic or magneto-electric battery are placed at intervals in the vats: they form the positive electrodes, and correspond in extent of surface with the articles to be coated, and face them on both sides. The articles (teapots, cruet-frames, forks, spoons, etc.) act as the negative electrodes, and are suspended by copper wires from brass rods laid lengthways over the vats, and connected with the battery. The articles plated are usually formed of nickel silver or German-silver, which is chosen on account of its silvery whiteness, a quality of great importance when portions of the coating of noble metal have been worn away by use. — To prepare the articles for plating, they are first boiled in a solution of potassa, to free them from grease; they are then quickly dipped in red nitrous acid, to remove any oxide that may have formed on the surface, and after this well washed in water, to remove every trace of acid. They are then suspended from copper wires, and dipped into a solution of mercury in cyanide of potassium, or some other mercurial solution, and afterwards washed in water, as before. The amalgamation of the surface effected by the last operation promotes the adhesion of the film of silver. The articles, having been weighed, are now immersed in the silvering solution, and left until a sufficient amount of silver has been deposited on them. Their condition at any time may be ascertained by weighing a test-object removed from the solution. In some electro-plating establishments the silvering solution is kept constantly stirred by simple mechanical arrangements; in others, continual motion is given to the suspended articles. On being removed from the vats the plated articles are well brushed with brushes of fine brass wire attached to a lathe, and cleaned with fine Calais sand; they are afterwards polished on revolving brushes with rottenstone, then by hand with soft leather and rouge, and, lastly, with the naked female hand. A lasting polish is given to some articles by burnishing with a burnisher formed of highly polished hardened steel, blood-stone, agate, or flint. The process of electro-gilding on the large scale is nearly the same as that of electro-plating or silvering, but, of course, plates of gold are suspended in the solution instead of silver plates.

**Electro-gilding** is effected in much the same way as electro-silvering. It is found, however, that magneto-electricity cannot be employed with advantage. Various gilding solutions are in use, but preference is usually given to the double cyanide of gold and potassium. The solution is generally used hot, its temperature ranging from 130° F. to the boiling-point. If the object to be gilt is not of copper, it is usual to coat it with an electro-deposit of copper before submitting it to the gilding solution. The coating of gold is generally very thin, and only a few minutes' exposure to the hot solution is necessary to effect its deposition. When the solution is fresh, a copper anode may be employed, its place being taken by a small gold electrode after the solution has been in work for some time. The presence of copper in the solution imparts a full reddish color to the electro-deposit of gold; and the tone of the metal may also be modified by the presence of salts of various other metals, such as those of silver. Sometimes only part of an object is to be gilt, such as the inside of a silver-plated cream-jug; in this case the vessel would be filled with the gilding solution, in which the anode of the battery is immersed. Gold is sometimes deposited not as a coating upon other metals, but as an electrotype in gutta-percha or in plaster moulds; small objects of elaborate workmanship being thus produced in solid gold, without the workmanship of the chaser and engraver.

Although copper, silver, and gold are the metals to which the attention of the electro-metallurgist is usually restricted,

it should be remembered that he is also able to obtain electro-deposits of a very large number of other metals. Many of these are not practically used, but one of them has of late years become of considerable importance. This is the metal *nickel*. In 1869 Dr. Isaac Adams of Boston, Mass., patented a process, now carried out on a large scale in this country, for depositing nickel from solutions of various double salts, especially from the sulphate of nickel and ammonium. The metal is deposited as a very thin but excessively hard coating, and has the advantage of not readily tarnishing or corroding even in a moist atmosphere. Hence it has become common to electro-nickel iron and steel objects for use on board ship, as well as gun-barrels, sword-scabbards, harness furniture, gas-burners, and various articles for household use.

**Iron**, like nickel, may be deposited from its double salts, and excellent results have been obtained by Klein, of St. Petersburg, with the double sulphate of iron and ammonium. Engraved copper-plates are much harder when faced with electro-deposited iron than when unprotected, and they consequently yield a much larger number of impressions before losing their sharpness. Plates for printing bank-notes have been treated in this way.

Not only can the electro-metallurgist deposit simple metals, such as those noticed above, but he is able likewise to deposit certain alloys, such as brass, bronze, and German-silver. The processes by which this can be effected are not, however, very generally used.

Among the minor applications of *E.-M.* we may mention the process of electrotyping flowers, insects, and other delicate natural objects. These are first dipped for a moment in a warm solution of nitrate of silver in alcohol, and then exposed to a reducing liquid, such as a solution of phosphorus in bisulphide of carbon; an electro-deposit may then be thrown down upon this metallized surface. Daguerreotypes are sometimes improved by coating them with a very delicate film of electro-deposited gold. Again, in some of the modern photographic processes for printing, copper electrotypes are taken directly or indirectly from the bichromatized gelatine. Of late years, too, a method of refining crude copper by means of *E.-M.* has been introduced, and is now successfully carried out on a large scale. Slabs of blister-copper are plunged into a solution of sulphate of copper, and form the anodes of a battery; the copper then dissolves, and is deposited in a condition of great purity at the opposite pole, most of the impurities sinking to the bottom of the depositing vat. The process should be restricted to copper which is free from any metals likely to be deposited along with the metal under purification.

Various solutions for plating and gilding have been recommended. We give below those generally employed.

1. Solvent solution. Cyanide of potassium, 2 oz.; distilled water or rain-water, 1 pint; dissolve. Other proportions may be employed. Used as a general solvent for salts of silver, gold, and platinum. — 2. Silver solution. Oxide of silver (not dried), 1 oz.; the solvent solution (No. 1), 1 pint. Used for the single-cell apparatus, its strength being maintained as the deposition proceeds by a fresh supply of oxide from time to time. — Cyanide of silver dissolved in solvent solution (No. 1). This is the solution generally employed for plating with a separate decomposition cell. — 3. Gold solution. Add to a pint of No. 1 oxide of gold  $\frac{1}{2}$  oz. — Cyanide of gold dissolved in solution of cyanide of potassium (No. 1).

**Electrometer, Electroscope**, an instrument for detecting the presence and quantity of electricity.

**Electrophorus**, an instrument for obtaining electricity by means of induction.

**Electro-Plating.** See ELECTRO-METALLURGY.

**Electroscope.** See ELECTROMETER.

**Electrotint**, a mode of engraving in which drawings are made with any substance insoluble in the solution of sulphate of copper. When the design is completed, the plate is immersed in the solution, and a reverse made by the electro-coppering process, and from this copies are printed. The process may be adapted to relief or to plate printing.

**Electrotyping and Stereotyping.** Electrotypes and stereotypes are metallic plates, fac-similes of the face of an engraved block or of a page or "form" of movable type, or of woodcuts and type combined; and no inventions or improvements relating to printing have proven of greater importance to printers, or have conferred greater benefits upon the public at large, than the original discovery of and the later improvements in the methods of making such plates. It has been claimed that, as early as 1690, John Muller, of

Leyden, Holland, made stereotypes. A few years later, Van der Mey, of the same city, soldered the bottoms of the type together, to prevent the pages being knocked over or "pied" previous to or while they were being printed from. Pages thus soldered could not be "distributed," — the "letter" could not be used a second time, and publishers could not afford to thus "lock up" their type. In 1725 Wm. Ged, of Edinburgh, Scotland, conceived the idea that a great saving would be effected in the cost of publishing books if, as soon as a page was set up and corrected, a fac-simile plate could be made, and the type immediately released for recomposition. Ged at once began his experiment, but two years elapsed before he succeeded in making perfect plates. Then came his greatest trials. In his process printers fancied that they saw the ruin of their craft, consequently they opposed it; publishers durst not avail themselves of the invention, and it was some years before it was put to any practical use. An edition of Sallust, published in Edinburgh, in 1736, was, we believe, the first and the only book printed from plates made by William Ged. After this the art was nearly lost sight of until 1796, when the Didots of Paris re-introduced it. They were successful, and within a few years stereotype plates were used to some extent by nearly all the leading printers of Europe. In 1813 stereotyping was introduced into the United States, and foundries were opened in New York, Boston, and Philadelphia.

Electrotyping, as applied to the production of plates for printers' use, is strictly an American art. Electro-plating was practised some years before electrotyping was accomplished, and experiments were made in England and France, with a view to the duplication of letter-press plates by a process similar to electro-plating, but they were not successful. In 1839 Mr. Joseph A. Adams, a wood-engraver, of the city of New York, began a series of experiments with the same end in view, and succeeded so well that, in 1841, an engraving printed from one of his electrotype plates was published in Mape's Magazine. It was not until five years later, however, that the art of electrotyping was reduced to a trade. In 1846 Mr. Daniel Davis, of Boston, a manufacturer of magnetic machines, undertook electrotyping as a business, and produced plates that were such perfect fac-similes of the originals that the superiority of electrotypes over stereotypes was at once acknowledged.

The process for making electrotypes and stereotypes is substantially as follows: The form to be electrotyped is laid, face uppermost, on the projection of the bed of the hydraulic press, to see that its surface is level and entirely free from all foreign matter, and that it is securely "locked up." When satisfied that it is all correct, the form is covered with graphite, well brushed in with a fine, soft brush, to prevent the wax mould from adhering to the form. The best moulding composition is simply unadulterated yellow wax, which must be boiled sufficiently long to evaporate all the water, but the utmost care must be taken not to subject it to too high a heat, as to scorch it is to render it worthless. The moulding-case is a flat-bottomed brass pan about a quarter of an inch deep; the inside is quite rough, that the wax may readily adhere to it, but the back is planed smooth and must be kept perfectly clean. Before the composition is ready to pour, the pan is placed on the bench set apart for that purpose and made perfectly level, when the wax is gently poured. If air-bubbles rise to the surface they are touched with the heated "building iron," and the pouring must be finished before the composition begins to cool. The wax when cool presents a smooth even surface. When the wax has partly cooled, but while still warm, it is carefully rubbed over with black lead, using for the purpose a soft brush. The form and the moulding-case both being ready, the operator laps the composition surface on the face of the form; the two are then placed in proper position, and the pressure gradually applied. A few seconds suffice to

form the wax mould, and the form is then drawn on the projecting table and the mould lifted from it. — In the mould, of course, we have the reverse of the face of the form, every white spot on the printed page is an elevation in the mould and every letter shown, and every black line in the cut is a hollow; when the plate is finished all this will be again reversed. Now type that is to be electrotyped should always be set up with high "spaces" and "quadrates," as they leave less waste space for the wax to fill up, and insure a sharper mould and a better plate; but where two blank lines come together, or where soft paper is to be used in printing, it is necessary that these blank spaces in the page should be deepened in the plate, else the paper will sink to the bottom of the too shallow cavity, and the printed page present an untidy appearance. This, where the white spaces do not cover more than one or two consecutive lines, is accomplished by the process of "building up." The operation requires a steady hand and a quick eye. It cannot be taught, and can be acquired only after long practice. The tool is called a *building-iron*. In shape it is not unlike a small fire-poker, except that at a point there is an arrow-shaped head. The building-iron is heated sufficiently to readily melt wax, the operator with this tool in one hand and a strip of wax in the other, holds the point of the iron close to the spot where the "building" is to be done, applies the wax, which melts, and running to the sharp point drops off on the mould, — if, perchance, it drops so as to cover the impression of a few letters, the mould is spoiled. — The mould having been properly built, it is now ready for black-leading, this being necessary to give it a conducting surface, without which it could receive no deposit of copper. In small foundries the moulds are black-leaded by hand, but in large establishments there are black-leading machines; after the moulds are well brushed, the surplus is blown out with a bellows and the mould placed in a copper solution. — These vats contain a solution composed of sulphate of copper, dilute sulphuric acid, and water. Sheets of copper half an inch thick and as long as the vats are suspended edgewise in the solution and reach to within a few inches of the bottom of the vat. Thus, the faces of the moulds are directly opposite and but a short distance from the broad surfaces of these copper plates. The broad bands running from the electro-magnetic machine battery to the vats are copper conductors, attached to the positive poles of the battery; on the top of the sides of the vats are the negative conductors; the wires running up and down just at the left of the battery, in combination with a movable break, constitute the "switch," which enables the operator to regulate the electric current. If the current is too strong the copper will be burned and the deposit will be granular; if too weak, the deposit will be but slowly made. To complete the circuit, one end of a strip of brass is attached to the negative conductor, the other end is placed against the edge of the metallized mould. The copper held in solution in the bath is attracted to the mould, and soon forms a shell, the thickness of which depends upon the strength of the current and the length of time the mould remains in the bath. — The time occupied in forming the shell with the acid battery (the old way of doing) is from twelve to fourteen hours, the electric machine battery does the work in two to three hours. <sup>1763</sup> of an inch is about the usual thickness of the shell, though they are made both heavier and lighter, — from <sup>1000</sup> to <sup>1125</sup> of an inch. The required thickness having been attained, the mould is removed and well washed in cold water; it is then placed in an inclined position in a sink and warm water poured over the face; this softens the wax, and the shell is carefully lifted from the mould and thoroughly washed in hot lye. The shell is now to be backed with metal composed of tin, antimony, and lead; but this backing metal would not adhere to the copper, they must be soldered together. The shell is laid face downwards in a backing-pan, which rests on tables whose tops are adjusted to perfect levels by thumb-screws. The interior of the shell is washed with muriate of zinc, and a sheet of rolled solder is spread over its surface. The pan and shell are then floated in the molten backing-metal to melt the solder. The pan is then placed on the level table, and the backing metal poured on to the copper shell. When the plate has cooled it is removed from the backing pan; the waste edges are sawn off. It then goes to the finishing-bench, where expert men straighten it (for in cooling it has probably warped a trifle, and the face must be made level), and look it over carefully to detect and correct any imperfections. It then goes to the planing-machine, and the back is rough planed; from there back to the finishing-bench again, where it is completely straightened; then to the smooth planers, where the plate is reduced to its proper thickness and the back made perfectly smooth, and from there to the bevelling-machine, if bevelled edges are required. Routing is cutting down the face of the plate, where any considerable white space is to show in the printed page, as beside cuts or between widely separated lines. Small movable cutters, revolving very rapidly, do the work. If the plate is to be mounted, it is taken to the proper bench, and is there fastened to mahogany blocks, thoroughly seasoned and planed by machinery to the proper height. The blocked plate is then squared at the side planer, and if to be mortised for the insertion of lines of type, that operation is performed by the aid of the drilling-machine and the gig-saw.

Finally it reaches the finishing-bench, where it receives the final touches.

**Stereotyping by the Papier-Mache** process is a quite recent invention. It is the simplest and quickest method of making ordinary plates, and the only method by which circular plates can be made. To prepare the matrix a sheet of soft, unsized paper is laid on any smooth surface and three or four sheets of tissue-paper pasted on it. To make the mould, a piece of this prepared paper, the type having been previously oiled, is spread over the form, and gently beaten with a soft brush; the paper is thus forced into every crevice. A second sheet of soft paper is then pasted on the back of the matrix and the beating continued until the mould is of sufficient depth. The form is then removed to the drying-table, which is heated by steam. The matrix is covered with four thicknesses of soft woollen blanket, and a light pressure is applied, to prevent the mould from warping. After a minute or two the press is unscrewed, the blanket removed, and the mould lifted from the form. It is then placed between heated iron plates in the casting-machine, the type metal poured in, and in a second the stereotype is ready for the finishing processes.—In casting plates for the great daily papers, special casting-boxes and other appliances are used which we have not room to describe. They have cast and finished such plates in less than 9 minutes, and within 19 minutes from the time the last lines were placed in the form of type, the mould was taken, the plate cast, finished, put on the printing-press, and the press was in motion. It was not until this process of stereotyping was perfected that the present fast presses were practicable. These moulds may be used to make several casts.

We are indebted for the foregoing sketch to Messrs. Crum & Kingler, proprietors of the New York Manhattan Electrotype Foundry, one of the finest and most complete electrotype and stereotype foundries in the country. There, and in some few other establishments of New York, Philadelphia, and Boston, are daily produced those matchless plates which have placed American art far above the standard of English and French electrotyping.

**Electuary**, a sweetened medicine, of conserves and powders in a soft mass, of the consistence of thick honey.

**Elemi**, a resinous substance obtained from incisions made during dry weather through the bark of the *Amyris elemifera*, a tree which grows in Brazil and other parts of S. America. It is brought to us in yellow, tender, transparent lumps, which readily soften by the heat of the hand, have a strong aromatic odor, a hot spicy taste, and contain about 12½ per cent of ethereous oil. *E.* is used in making lacquer, to give toughness to the varnish. It is also used in medicine.

**Elephant**, the largest of quadrupeds, which is domesticated in the East and trained to service. The wild animals are also hunted for their tusks, which furnish the ivory of commerce, and their back teeth, or grinders, are also useful. The feet, trunk, etc., are eaten by the hunters; the tail is used for a fly-flapper. See **Ivory**.

**Elephant-Paper**, a very large kind of drawing-paper, 28 inches by 23.

**Elevation**, a plane; a geometrical perspective representation of a building, measured vertically in respect of the horizon.

**Elevator**, "a machine for transferring grain by raising it from the car, a bin, or the hold of a ship, to an elevated hopper, whence it is discharged by any one of a series of spouts directed to a bin for storage, or to the hold of a boat, a car, or to a run of stones. *E.* are used in flour-mills to carry the wheat to the upper story, where it is cleaned in the smut-mill; also to raise wheat, so cleaned, to a bin, whence it proceeds to the stones; also to raise the meal to the bolt, etc., as the case may be. *E.* are also used in many other machines for raising small objects or materials.—2. A platform or cage in a warehouse, hotel, mine, or elsewhere, for raising or lowering persons, goods, or materials to or from different floors or levels.—A building specially constructed for elevating, storing, and loading grain

into cars or vessels. These structures are very capacious both as to the capacity for handling and storing, but the construction is very simple. An *E.-leg*, so called, reaches into the bin, into which the contents of the wagons or cars are discharged. A strong belt, carrying a series of buckets, travels over a drum at the lower end and also over one at the upper end, where the buckets tip over and discharge into the upper bin. This has valved spouts, which direct the contents into either one of two deep parallel bins. The floors of these bins are over the tracks, and valves in the floor allow the contents of the bins to be discharged into cars or ships, which are brought beneath." (*E. H. Knight's American Mechanical Dictionary*.)—4. An instrument with which surgeons raise any depressed portion of bone, especially of the cranial bones.

**Eliot Fire Insurance Co.**, located in Boston, Mass., was organized in 1872. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$200,000. Net surplus, \$127,051.30. Total cap. and surplus, \$327,051.30. Risks in force, \$7,923,385. Premiums, \$98,135.37. Premiums received since the organization of the Co., \$594,230.65. Losses paid, \$198,787.65. Cash dividends paid to stockholders, \$90,000.

**Elizir**, in pharmacy, a name formerly applied to various compound tinctures, and to preparations supposed to contain the quintessence of other substances; still applied to several popular remedies. In popular parlance, an invigorating cordial.

**Ell**, an English measure of length equal to 45 inches, but now superseded by the imperial yard. The term is, however, still employed in designating the width of certain goods. The ell is also an old measure which varies in length in the countries of Europe where it is still sometimes used; the Dutch or Flemish ell is 27 inches. The proportion between Dutch ells and English yards is generally taken at 3 yards to 4 ells; but the real rate is 100 yards to 129⅔ ells. In Leipsic the ell is 22¼ inches; in Prussia 26¼ nearly. In Trieste the woollen ell is 26.6 imperial inches; that for silk 25.22 inches. The German ell is 21½ inches; the Scottish ell rather more than 37 inches.

**Elm**, a graceful forest-tree, of which there are several varieties, forming the genus *Ulmus* (Fig. 160). It attains to a great size, and lives to a

Fig. 160. — ELM.

great age. Its trunk is often rugged and crooked, and it is of slow growth. The color of the heartwood of elm is generally darker than that of oak, and of a redder brown. The sapwood is of a yellowish or brownish white, with pores inclined to red. It is in general porous and cross-grained,

sometimes coarse-grained, and has no large septa. It has a peculiar odor. It twists and warps much in drying, and shrinks very much both in length and breadth. It is difficult to work, but is not liable to split, and bears the driving of bolts and nails better than any other timber. The wood of the *Ulmus Americana*, like that of the European elm, is of a dark brown color, and is liable to decay when exposed to the alternations of moisture and dryness; and when cut transversely or obliquely to the longitudinal fibres, it exhibits the same numerous and fine undulations; but it splits more easily and has less compactness, hardness, and strength, weighing, when perfectly dry, only 33 pounds to a cubic foot. The principal uses to which this timber is applied are for making naves or hubs to wheels, for piles and foundation-pieces to mills, canal-locks, and for many other purposes where strength is required, and the work is constantly buried in water or mud. In the State of Maine it is occasionally employed for the keels to vessels, for which purpose it is well adapted on account of its size. It is also employed for the swing-trees of the carriages of great-guns; and in some parts of the country, where more appropriate wood is not to be found, it is used for making ox-yokes, sleds, and other implements of husbandry. The bark, which is easily detached from the tree during 8 months of the year, is sometimes used for making bast-mats, ropes or withes, and for the bottoms of chairs. The wood, when dry, makes excellent fuel, and, when burned, yields a large proportion of ashes, which abound in alkaline salts.

**Elmira and Williamsport R.R.** runs from Williamsport, Pa., to Elmira, N. Y., 76.70 m. This Co., whose offices are in Philadelphia, was chartered in 1832 as the Williamsport & Elmira R.R., was reorganized under present name and the road leased in 1863 to the Northern Central R.R. Co., for 99 yrs., for \$165,000 per annum and interest on equipment. *Financial statement:* Cap. stock, common, \$500,000; preferred, \$500,000; funded debt, 1st mortgage 7% bonds, payable 1880, \$1,000,000; income 5% bonds, payable 1862, \$570,000; real estate (Elmira) mortgage, 7%, \$50,000.

**Elvas Plums**, a kind of dried prune, a dessert fruit sold in boxes.

**Embale**, to pack up or bind goods in a bale or package.

**Embank**, to enclose with a mound; the term is applied chiefly to banks of earth, by which water is kept out from land that has been reclaimed, or that is liable to inundation.

**Embankments**, artificial mounds of earth, raised by the sides of rivers, fens, etc., or for levelling the line of road for a railway.

**Embar**, a liquid measure of Sweden, equal to 20½ gallons.

**Embargo**, a temporary injunction by the supreme government of a country prohibiting individuals or commodities from being conveyed beyond seas, or vessels from leaving their ports. There are two kinds of *E.*, the one where the sovereign detains the vessels of an adverse nation in his harbors, the other where he suspends the sailing of those of his own subjects. The former generally takes place on a declaration of war; the latter is a matter of internal administration, involving, in this country, as in England, questions as to the power of the National Government. On the issuing of a declaration of war, it is not unusual to lay an embargo on such vessels of the country declared against as may happen to be in the ports of the government declaring, or only on vessels

laden with articles of which it is thought expedient to prevent the exportation. This step is reconciled with the old principles of the law of nations by the view that the *casus belli* and virtual declaration will have taken place before the literal proclamation. With regard to the right of placing an *E.* on American ships or subjects, it is of a wider range in time of war than in time of peace, and seems in the former case to embrace all those occasions where the prohibition can be presumed necessary or useful to the national defence. In time of peace, however, the government must exercise the right within the limits which the law allows, the extent of which is somewhat doubtful. In 1766 a proclamation was issued in England, prohibiting the exportation of corn, on account of the risk of famine; but it was thought necessary to pass an act of indemnity (7 George III. c. 7), which characterized the order as one that "could not be justified by law, but was so much for the service of the public, and so necessary for the safety and preservation of the British people, that it ought to be justified by Act of Parliament." The proprietors of the embargoed ships were indemnified, which they would not have been had the *E.* been legal. Loss by *E.* is one of those which underwriters have to make good; while a breach of *E.* is one of those breaches of warranty which release them from their obligation. An *E.* laid on by the government of the country in whose port a vessel is, being but a temporary suspension, does not dissolve a contract for the employment of the vessel. But in the case of an American citizen freighting a vessel which is subject to *E.* on account of hostility to the country to which the ship belongs, he will not be responsible for terminating the contract if the object of the voyage would be likely to be defeated by delay.

**Embark**, to ship; to proceed on board a vessel or boat; to engage or take part in any business.

**Embellishment**, the act of adorning or enriching; ornament, decoration.

**Embers**, small lighted coals or the ashes of burning wood.

**Embezzlement**, in law, a peculiar form of theft which is distinguished from the ordinary crime in two points: 1. It is committed by a person who is in the position of clerk or servant to the owner of the property stolen; 2. The property when stolen is in the possession of such clerk or servant. The definition of *E.* as a special form of theft arose out of the difficulties caused by the legal doctrine that to constitute larceny the property must be taken out of the possession of the owner. Servants and others were thus able to steal with impunity goods entrusted to them by their masters. An *E.* is in substance, and essentially, a larceny, aggravated rather than palliated by the violation of a trust or contract, instead of being, like larceny, a trespass. In England, the crime is made a felony, punishable by not more than fourteen nor less than five years of penal servitude. In this country the punishment varies in the several States, but is generally scarcely less severe.

Sec. 520 of the U. States Revised Statutes, relating to *National Banks*, is as follows: "Every president, director, cashier, teller, clerk, or agent of any association who embezzles, abstracts, or wilfully misapplies any of the moneys, funds, or credits of the association, or who, without authority from the directors issues or puts in circulation any of the notes of the association; or who, without such authority, issues or puts forth any certificate of deposit, draws any order or bill of exchange, makes any acceptance, assigns any note, bond, draft, bill of exchange, mortgage, judgment, or decree; or who makes any false entry in any book, report, or statement of the association, with intent, in either case, to injure

or defraud the association or any other company, body politic or corporate, or any individual person, or to deceive any officer of the association, or any agent appointed to examine the affairs of any such association : and every person who with like intent aids or abets any officer, clerk, or agent in any violation of this section, shall be deemed guilty of a misdemeanor, and shall be imprisoned not less than five years nor more than ten."

*E by s-amen.* "For wilfully damaging the vessel, or embezzling or wilfully damaging any of the stores or cargo, any seaman is punishable by forfeiture out of his wages, of a sum equal in amount to the loss thereby sustained, and also, at the discretion of the court, by imprisonment for not more than 12 months." (*Section 4595 of U. States Revised Statutes.*) If the individual who has committed the wrong be unknown, those of the crew upon whom the presumption of guilt rests, stand as sureties for each other, and they must contribute ratably to the loss. Some of the cases in the books have established a general contribution from all the crew for such *E.*, even when some of them were in a situation to repel every presumption of guilt; but neither public policy nor principles of justice extend the contribution or forfeiture of wages for such *E.*, beyond the parties immediately in *delicto*.

**Embossing** is the art of producing raised portions or patterns on the surface of metal, leather, textile fabrics, cardboard, paper, and similar substances. Strictly the term is applicable only to raised impressions produced by means of engraved dies or plates brought forcibly to bear on the material to be embossed, by various means, according to the nature of the substance acted on. Thus raised patterns produced by carving, chiselling, casting, and chasing or hammering are excluded from the range of embossed work. *E.* supplies a convenient and expeditious medium for producing elegant ornamental effects in many distinct industries; and especially in its relations to paper and cardboard its applications are varied and important. Crests, monograms, addresses, etc., are embossed on paper and envelopes from dies (see *DIE-SINKING*) set in small hand-screw presses, a force or counter die being prepared in leather faced with a coating of gutta-percha. The dies to be used for plain *E.* are generally cut deeper than those intended to be used with colors. Color *E.* is done in two ways,—the first and ordinary kind being that in which the ink is applied to the raised portion of the design. The color in this case is spread on the die with a brush, and the whole surface is carefully cleaned, leaving only ink in the depressed parts of the engraving. In the second variety—called *cameo E.*—the color is applied to the flat parts of the design by means of a small printing-roller, and the letters or design in relief are left uncolored. In *E.* large ornamental designs, engraved plates, or electrotypes therefrom are employed, the force or counterpart being composed of mill-board faced with gutta-percha. In working these, powerful screw-presses, in principle like coining or medal-striking presses, are employed. *E.* also is most extensively practised for ornamental purposes in the art of bookbinding. The blocked ornaments on cloth covers for books, and the blocking or imitation tooling on the cheaper kinds of leather-work, are effected by means of powerful *E.* or arming presses. (See *BOOKBINDING*.) For impressing embossed patterns on wall-papers, textiles of various kinds, and felt, cylinders of copper, engraved with the patterns to be raised, are employed, and these are mounted in calendar frames, in which they press against rollers having a yielding surface, or so constructed that depressions in the engraved cylinders fit into corresponding elevations in those against which they press. The operations of *E.* and color printing are also sometimes effected together in a modification of the ordinary cylinder printing-machine used in calico-printing, in which it is only necessary to introduce suitably engraved

cylinders. For many purposes the *E.* rollers must be maintained at a high temperature while in operation; and they are heated either by steam, by gas jets, or by the introduction of red-hot irons within them. The stamped or struck ornaments in sheet metal, used especially in connection with the brass and Britannia metal trades, are obtained by a process of *E.*—hard steel dies with forces or counterparts of soft metal being used in their production (see *BRASS*). A kind of embossed ornament is formed on the surface of soft wood by first compressing and consequently sinking the parts intended to be embossed, then planing the whole surface level, after which, when the wood is placed in water, the previously depressed portion swells up and rises to its original level. Thus an embossed pattern is produced which may be subsequently sharpened and finished by the ordinary process of carving.

**Embouchure**, the mouth of anything, as of a river or harbor; of a cannon, a bottle, a wind instrument, etc.

**Embrocation**, a pungent oil, or medicinal spirit, used as an external application to moisten or rub diseased parts of the body.

**Embroidery** is a general name for many different modes of giving pattern and ornament to textile fabrics. The most evident mode is to take a piece of woollen cloth, net, gauze, etc., and apply any decorative patterns to it by needle and thread. The ancients were very fond of this method of producing rich tissues; and in India, China, and Persia the art is extensively practised at the present day, especially with gold and silver threads, spangles, beads, bugles, feathers, almost anything, in fact, that has richness and diversity of color. The *sampler* is a well-known kind of juvenile *E.*-needlework upon an open canvas. *Berlin-wool work* is a higher kind, but similar in principle; it obtained its name from having been introduced first at Berlin, where a print-seller invented the convenient pattern papers which are used in this work. *Lace E.* and *muslin E.* describe themselves in their names. *Tapestry work* is described under *TAPESTRY*. The machinery employed in most sorts of *E.* consists simply of some kind of frame in which the material can be stretched out flat. There are, however, *embroidering-machines* which increase many fold the rapidity of working. One such machine, invented by M. Heilmann, of Mülhausen, enables a woman to embroider with 100 needles at a time. The needles have a point at each end, and an eye in the middle; and the action bears some resemblance to that of the well-known sewing-machine, except in having the web or cloth upright instead of horizontal. The needles are attached to a kind of carriage; the carriage travels to and fro towards the web and back; the needles convey their threads in and out of the web at every movement of the carriage; pincers grasp the needles at each end alternately, to pull them through, and prepare them for their return journey; and then a pattern becomes incorporated with the web by every distinct needle.

*Imp. duty*: manuf. of cotton, linen, or silk, if embroidered or tamboured, in the loom or otherwise, by machinery or with the needle, not otherwise provided for, 35 per cent. — Articles embroidered with gold and silver, or other metal, 35 per cent.

**Emerald** [*Fr. émeraude*; *Ger. Smaragd*; *It. smeraldo*; *Sp. esmeralda*], a beautiful ornamental stone of a peculiar green color, which it derives from the intermixture of a small portion of chrome. The common form of its crystal is the hexahedral

prism; transparent or translucent; lustre vitreous; sp. gr. 2.75. It scarcely differs from beryl, except in color, and ranks next to the diamond in value. The finest are brought from Peru, but fair varieties are found in Bavaria, Siberia, and India. A fine *E.* weighing 4 or 5 gr. is worth about \$5 per gr.; one of 10 gr. about \$10 per gr.; one of 15 gr. \$15 to \$20 per gr.; and so on in proportion to the increase in size. One of 24 gr., if of pure water, is worth about \$500. *Imp. duty*, same as diamond.

**Emerald Green.** See BICE.

**Emeraldine.** See ANILINE (BLUE AND GREENS).

**Emery** is an impure, amorphous, compact, and opaque variety of corundum, and consists of alumina, with a small percentage of silica and peroxide of iron. It occurs in Spain, the isles of Greece, and other localities, and derives its name from Cape Emery, in the island of Naxos. Its hardness is so great that it scratches and wears down nearly all minerals except the diamond; hence the use of its powder for cutting and polishing glass and various other hard substances.

Fig. 161. — EMERY-WHEEL.

For commercial purposes, the lumps of *E.*, as taken from the mine, are broken into pieces about the size of a hen's egg, which are then crushed under stampers, similar to those used for pounding metallic ores. The coarse powder is then sifted through sieves covered with wire-cloth of different degrees of fineness, by which it is sorted into different sizes. According to the degree of fineness, it is called *corn*, *coarse grinding*, *grinding*, *fine grinding*, *superfine grinding*, *coarse flour*, *flour*, *fine flour*, and *superfine flour E.* In many instances *E.* powder cannot be conveniently used unless it is cemented to some substance which can be held in the hand, as paper, cloth, and sticks.

*E.-cake* consists of *E.* mixed with a little beeswax, so as to constitute a solid lump, with which to dress the edges of buff and glaze wheels. The ingredients should be thoroughly incorporated by stirring the mixture while fluid, after which it is frequently poured into water, and thoroughly kneaded with the hands, and rolled into lumps before it has time to cool. The *E.-cake* is sometimes applied to the wheels while they are revolving; but the more usual course is, to stop the wheel, and rub in the *E.-cake* by the hand. It is afterward smoothed down by the thumb.

*E.-cloth* only differs from *E.-paper* in the use of thin cotton cloth instead of paper, as the material upon which the *E.* is

fixed by means of glue. The *E.-cloth*, when folded around a file, does not ply so readily to it as *E.-paper*, and is apt to unroll. Hence smiths, engineers, and others prefer *E.-paper* and *E.-sticks*; but for household and other purposes, where the hand alone is used, the greater durability of the cloth is advantageous.

*E.-paper* is prepared by brushing the paper over with thin glue, and dusting the *E.-powder* over it from a sieve. There are about six degrees of coarseness. Sieves with 30 and 50 meshes per linear inch are in general the coarsest and finest sizes employed. When used by artisans, the *E.-paper* is commonly wrapped around a file or slip of wood, and applied just like a file, with or without oil, according to circumstances. The *E.-paper* cuts more smoothly with oil, but leaves the work dull.

*E.-sticks* are rolls of board, about 8 or 12 inches long, planed up square, or with one side rounded like a half-rounded file. Nails are driven into each end of the stick as temporary handles; they are then brushed over, one at a time, with thin glue, and dabbed at all parts in a heap of *E.-powder*, and knocked at one end to shake off the excess. Two coats of glue and emery are generally used. The *E.-sticks* are much more economical than *E.-paper* wrapped on a file, which is liable to be torn.

*E.-wheels* are "solid wheels consisting of a mixture of powdered *E.* with shellac, fused and rolled upon a stick. When carefully mounted upon a mandril (Fig. 161) and run at a high speed, the abrading power of such wheels is wonderful. They will instantly take the teeth off the hardest file and reduce it to a plane, smooth surface, or will cut away parts of chilled castings that a file will not touch. The grains of *E.* are the cutting-points or teeth, and do not grow dull although brought into contact with metal hard enough to turn the teeth of a file at one stroke. The rapidity of abrasion depends not only on the velocity of movement, but upon the size of the grains of *E.* For very heavy work, such as taking the rough edges off castings, very coarse *E.* is used, while the finer sorts are made into wheels for fine grinding and surface work on brass or steel. In using *E.-wheels* care must be taken to maintain the proper speed, and not to press the work too strongly against the surface. If too much pressure is used, the wheels will not cut so fast, and are liable to wear away unequally and to get out of true. A rest should always be used to support the work and prevent it from vibrating upon the wheel. The bearings should be kept in good order and well lubricated. Good *E.-wheels* are uniform in texture. The material with which the *E.* is combined must have great cohesive strength to resist the tendency of the wheels to fly asunder when revolving at high speed, and to retain the grains of *E.* firmly, and yet wear away evenly, leaving the cutting angles exposed, and not glaze or "gum up." It must not soften or melt under the heat generated by the friction in cutting the work, and must be free from noxious qualities. As such wheels are run at high velocities, they require to be very carefully and exactly hung, and to be kept perfectly true so as to prevent vibrations. They should not "wedge" upon the mandril, or even fit it closely, for expansion by heat might burst the wheel, and the flanges at the side should not be too strongly screwed up. A wheel 36 in. in diameter may have 611 revolutions per minute, and one of 12 in. 1,800 revolutions." — *Johnson's Encyclopedia*.

*Imp. duty*: *E.* ore or rock, \$6 per ton; *E.* manufactured, ground, or pulverized, 1 ct. per lb.; *E.* grains, 2 cts. per lb.; *E.* cotton cloth, 35 per cent.

**Emetics**, a class of drugs which produce vomiting, by the influence of some peculiar and specific action on the nerves of the stomach, and independent of smell, taste, or local irritation. The principal *E.* are ipecacuanha and tartar *E.* (tartarated antimony), and their preparations; and the sulphates of zinc and copper.

**Emigration** is the act of leaving the country or place in which one has previously resided, with the view of residing in some other country or place. Persons so leaving the place of their residence are called emigrants; and the term "immigrants" is employed to designate persons arriving from a distance in some place or country with the intention of settling in it. Persons leaving a country for a while, to which they intend to return, are not reckoned emigrants. This term is

appropriated to those who leave their present habitations to establish themselves permanently elsewhere. The motives which lead to *E.* are various in the extreme; but, whatever its immediate cause may be, all emigrants expect either to avoid some considerable evil, or to improve or amend their situation. The striking modern form of *E.* is the removal of individuals and families from their native seats to distant countries in large numbers, yet without concert and without apparent distress, silently and intelligently, the emigrants knowing what they are leaving and whither they are going. *E.* of this kind, like the commerce in commodities, does not advance rapidly for a long period. The first adventurers have often a rough experience, and do not invite others, but gradually the number who succeed increases, and in their letters home encourage relatives and friends to follow their example, and not unfrequently supply the means of acting upon their advice. This, in a constant and cumulative form, comes to have in real and wholesome influence than all the *E.-aid* societies ever established, however useful these may have been in their place. The traffic of the steam navigation companies during the last thirty years would show how largely the volume of free and well-considered *E.* has thus been increased; and, indeed, it may be observed that *E.* of this kind has received much the same impetus as material commerce from the ocean steamers, railways, telegraphs, and other greatly improved means of transmission. The movement is liable to its own fluctuations; it ebbs and flows from one year to another; but of its permanence and extension there can be no reasonable doubt. The year 1847, in which the *E.* from Great Britain rose to 258,270, marks the beginning of unwonted increase, sustained over many years in succession, and, with some exceptional years, sustained, indeed, to the present time. The average annual *E.* in the five years ending 1853 was 323,002, whereas from 1815 to the same year (1853) it had only been 97,269. The Irish famine, ensuing on an almost total failure of the potato crops, was the first in the order of events to which this remarkable increase of *E.* is to be ascribed; but the Californian and Australian gold discoveries, the failure of the European revolutions of 1848, and the wonderfully growing prosperity of the U. States, prolonged the impulse which had first been given by a sharp distress affecting more parts of Europe than Ireland, and placed *E.* on the more voluntary and substantial basis which has characterized it of late years. The way was made so plain by the ocean steamers and railways, which trade and capital were bringing into rapid action, that larger numbers of people saw the advantage of passing over great distances from one hemisphere to another. It was not until 1855 that any relapse occurred in the large annual totals of *E.* from Great Britain; and so late as the ten years from 1869 to 1878 the average number per year of emigrants from British ports was 217,287. It must be said, however, that during these ten years British emigration was to a great extent balanced by immigration. During the year 1877, for instance, there were 93,557 immigrants, British and foreign, which, deducted from the total of 104,387 emigrants, left an excess of but 10,830 emigrants.

The following table exhibits the number of emigrants from Great Britain to British North America, the U. States, and Australasia, and the total number (the latter figure including the comparatively small number going to other than these three destinations) in each of the 64 years from 1815 to 1878.

Year.	British N. America.	U. States.	Australasia.	Total.
1815....	680	1,209	.....	1,889

Average annual *E.* for Great Britain from 1815 to 1878, 135,649.

The increase in *E.* was not confined to Great Britain. From the N. of Europe — from Germany and Scandinavia — there has been during the same period a largely increased *E.*, proceeding under much the same incitements and facilities as from England, Scotland, and Ireland. From France the *E.* has not been so marked as from many less populous countries. The German race have peopled the U. States so largely as to have become a prominent element in the American republic; but no one hears of the French as one of the constituents of a commonwealth which they helped materially to found. The *E.* of France follows her own colonies and traditions chiefly; it is found in Louisiana and in Canada, and almost everywhere discursively and thinly; and in much the same way the Span-

iards and Italians still lean in their *E.* to La Plata and S. America, where there is a trace of ancestry, and their language is spoken. The industrial motive and faculty, however, now draw emigrants from all the European nations into the most various parts of the New World. The Chinese themselves — the most numerous while the most isolated nationality in the world — have also become emigrants in large numbers, though it is obvious that the Chinese *E.* to our Pacific coast has not for its object a permanent change of country, and is more of the nature of a transfer of labor for a term of years than a definite *E.* of both sexes and of families. A constant coming and going is the feature of *E.* from China. The Chinese have a superstitious desire to die within the borders of their own sacred land. Nevertheless, their strong and persistent movement to the Western world is a significant phenomenon. It has broken through all restraints at home, and it has held its ground to this day, in the face of no little social hostility, from San Francisco to New York and other cities on the Atlantic seaboard (see CHINA). *E.* is now so widely practised, and has been rendered by improved means of transit so safe and expeditious, that its continued progress is not only sure, but one may foresee, from the various forces in play, that at no distant time it will have become, over the largest portion of the world, as familiar as migration from one province of the same country to another. The attitude and duties of states, and of the populations of states, towards a movement which comes into contact at many points with existing laws and interests — laws of naturalization, military conscription, and allegiance, with asserted rights of labor, and with social, religious, and international prejudices — have thus become questions of much importance. Nothing is more certain than that nearly all the old countries suffered in past times from want of *E.*, unless it be that all the new countries have been greatly benefited by it. Leaving China out of view, where foreign immigrants have only been tolerated under treaties extorted by force of arms, there has been a general approval of *E.* on the one hand, and of immigration on the other. In Great Britain the population are singularly free to choose either their own country or its colonies or other countries as the place of their abode. They are under no compulsory military service; and *E.* has been actively encouraged by societies and protected by the government for half a century. The greatest obstacle to free *E.* from the continent would appear to be the system of military conscription. Every German of 20 or 21 years is liable to personal service in the standing army for seven years — three of active service, four in the reserve — and to other five years in the landwehr, with the landsturm behind the landwehr making further demands on the time and liberty of the subject. In France a similar system is now enforced, though under more liberal exemptions. It is but fair to state that Germany, exclusive of Prussia, has up to this time been sufficiently free in its *E.* to have sent to the U. States, from 1820 to 1870, not fewer than 2,207,500 persons, which is nearly as many as those who came from Ireland to this country in the same half-century, viz., 2,700,493. But from Prussia, where the conscription has been longest in rigorous operation, the number of emigrants to the U. States, in the same period, has been only 100,983, and from France 245,812. Though the conscription may not be the sole cause of this, yet the demands made by the great military powers on the drilling and fighting services of the

whole youth and manhood of their populations are obviously obstructive to the pursuit of industry and fortune in foreign countries or in colonies. These demands may be relaxed from time to time, while the system itself is maintained; but they are relaxed with a grudge, and the governments acquire inordinate ideas of the irrevocable allegiance of their subjects. If the latter are permitted to emigrate it is under condition of being liable to recall on brief notice to the standards of their country; and an armed truce, such as has prevailed in the most civilized nations of the continent of Europe during five or six years of peace, might soon be as detrimental to free *E.* as war itself, under which it usually ceases for the time. From Russia none can emigrate without permission of the czar; and a similar despotism over the subject is the rule of the Ottoman empire. A state may be within its reasonable and proper line of duty in promoting and aiding either *E.* or immigration. But that the permission of the state should be necessary to the one process or the other is inconceivable, save in some rare and dire emergencies of war or politics. — The duty of states in regard to *E.*, viewed in what must now be the generally accepted light of a necessary and wholesome function of the general economy, thus resolves itself into a duty of regulation and guardianship under the two categories, always presented, of the countries which the emigrants leave, and the countries to which they go. The one are bound to see that emigrant ships are well found and not overcrowded, and that adequate arrangements are made for the provisioning, health, and safety of the passengers in their transit; while the other are bound to give them shelter and guidance on landing, to protect them from imposture, and to see that all pre-engagements made with them be fulfilled. Of the regulations for the reception of immigrants, the arrangements at New York afford probably the best example. No place in the world has had more to do with their reception than our great seaport; and measures have been adopted here by which the abuses once prevailing have been overcome, and at the same time all the arrangements for the comfort, security, and guidance of immigrants have been placed on a satisfactory basis. Emigrant ships are visited six miles from the port by health officers, and any who may be sick or diseased are removed to hospitals under the care of the commissioners of *E.* or the quarantine commission. The others are required to land at Castle Garden, where there is a large rotunda capable of accommodating 4,000 persons, and where every immediate want of the immigrants may be supplied without leaving the depot. Letters may be written for them, or telegrams despatched to friends, or friends may be introduced immediately on their credentials being presented. The utmost care is taken to guard the immigrants from falling into bad hands, and every information is afforded them as to how they shall best proceed in their respective objects. The supervision thus exercised in the port is extended over the railroads to the various parts of the Union to which immigrants may be bound. Besides such arrangements, no less honorable to the authorities of a country than encouraging to the emigrant, direct inducements have frequently been held out to settlers, in the form of grants of land or land at a cheap price, and in assisted or free passages. — The question whether countries receiving emigrants may not be called upon in some cases to check the flow of immigration within their borders is less free of difficulty than any similar

question as regards the countries from which emigrants proceed. An example of what may happen is now seen in Utah Territory, where the Mormons are not only at variance with the republic on so cardinal a point as the civil law of marriage, but almost at open war with the federal jurisdiction. Similar perplexities arise from the Chinese immigrants introducing customs and observances which, though called religious and claim-

ing toleration, can be regarded as contrary to civil order, morality, and decency (see CHINA). Some dilemma of the same sort may even occur in the emigrant-giving countries, as, for instance, when English trades-unionists, while deriving all the profit of a large outward flow of labor, fall upon foreign workmen who immigrate into Great Britain with a violence and disorder which the law has not yet learned or been able to prevent.

**Emissary**, a secret agent; a person sent on a private message or business.

**Emollients**, a medicinal application which softens, soothes, or allays irritation, and alleviates inflammatory soreness, swelling, and pain. *E.* of honey, gum, sugar, and eggs are among the chief internal articles; and poultices, fomentations, and hot water, the best of the external.

**Emoluments**, perquisites, fees, or salary; the profits arising from an office or employment.

**Empire City**, a fire insurance Co. of New York City, organized 1850. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$200,000; net surplus, \$102,000.07; total cap. and surplus, \$302,000.07; risks in force, \$9,445,228; premiums, \$54,343.03; premiums received since the organization of the Co., \$1,955,977.47; losses paid, \$893,990.27; cash dividends paid to stockholders, \$676,000.

**Empiric**, a quack, a pretender; an uneducated or irregular practitioner.

**Emplette** [Fr.], a bargain or purchase.

**Employé** [Fr.], a clerk; one engaged in the service of another.

**Employer**, a master; one who hires and directs the labor of others.

**Empois** [Fr.], potato or wheat starch.

**Emporium**, in a general sense, signifies a city or a place where extensive commercial transactions are carried on; but it is more particularly applied to the commercial centre of a country, or the place to which buyers and sellers from various countries resort.

**Emporium Fire Insurance Co.**, located in New York City, organized in 1873. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$200,000; net surplus, \$321.06; total cap. and surplus, \$200,321.06; risks in force, \$5,234,335; premiums, \$29,580.99; premiums received since the organization of the Co., \$292,717.72; losses paid, \$111,767.30; cash dividends paid to stockholders, \$66,000.

Fig. 162. — Emu.

**Empress-Cloth**, a light cloth for ladies' dresses, all wool, or with cotton warp and wool weft. It is usually 28 inches in width, and resembles merino, except that it is not twilled.

**Emptying**, a discharging or pouring out the contents of a package or vessel.

**Empty Packages**, returned cases from the purchaser to the sender of the goods, consisting for the most part of casks, barrels, crates, sacks, etc., which are transported free, or at a very low

charge, by the railroad companies. They are admitted free of duty when they have been exported full, and are of American manufacture.

**Emu**, the Australian ostrich, *Dromains Novæ Hollandiæ* (Fig. 162). Both the eggs and flesh are esteemed excellent for the table. The plumes are readily dyed of various colors, and appear to some extent in commerce as a substitute for ostrich feathers. The skin produces 6 or 7 quarts of oil, which is used in pharmacy.

**Emulsion**, a milky preparation formed by the mechanical admixture of oil and water, by means of some other substance that possesses the power of combining with both.

In the preparation of *E.* the oily or resinous ingredients are usually suspended by means of mucilage of gum arabic, almonds, or yolk of egg. 1 dr. of the first, made with equal parts of gum and water; 1 oz. of the second (usually 26 in number); and one in number of the last, will form 2 dr. of any oil into an *E.* with about 1 oz. of water, gradually added. In some cases, instead of the above substances, a little liquor of potassa is employed, by which a saponaceous *E.* is formed. In all cases the mucilage or other viscid substance should be put into the mortar before anything else. The oil or resinous matter may then be very gradually rubbed in, taking care not to add it more quickly than it can be subdued by the pestle, and if, during this part of the manipulation, the mixture should begin to assume a breaking or curdling appearance at the edges, a few drops of water must be immediately incorporated with it, before adding the remainder of the oil. From the want of this precaution, it is common for an *E.* suddenly to lose its tenacious consistence in the mortar, and it is then in vain to endeavor to restore it. After the oil is thoroughly incorporated some care is requisite to avoid separating it again by too hasty an effusion of the water or other fluid of the mixture. If any alcoholic or acid liquid is to be added, it must be at the very end of the process. Indeed, the addition of an acid liquid, even a slightly acrescent sirup, will often entirely destroy an emulsion. An excellent method of preparing *E.* of resins and gum-resins is to put the article into a marble or wedgewood mortar, and to pour over it about 4 times its weight of rectified spirit, which is then to be ignited, and the mixture triturated until an equal consistence is obtained. The liquid is then to be added gradually, and the whole patiently triturated or shaken until cold. Yolk of egg or mucilage may be added to the fluid resin or gum-resin, if desired, as in the common method, but an excellent *E.* may be made without them. The presence of soluble salts in an *E.* is apt to occasion the separation of the oleaginous portion. Spirit produces the same effect in those which are made with yolk or mucilage; and acids in those made with an alkali. The addition of these substances to *E.* should be therefore avoided as much as possible. *E.* of wax, spermaceti, oil of turpentine, and balsam of copaiba, are the most readily and completely formed with yolk of egg. Volatile oils are more readily made into *E.* if mixed with an equal volume of some simple fixed oil, before proceeding to operate on them. Scammony is generally formed into an *E.* with milk; and resin of jalap, with almonds and water.

**Enactment**, the passing of a bill into a law; the act of voting, decreeing, and giving validity to a law.

**Enamel** [Fr. *email*; Ger. *schmelz*; It. *smalto*], a species of vitreous varnish, colored with metallic oxides, applied in a thin stratum to brightly polished metallic surfaces (copper or gold), on which it is fused by the flame of a lamp urged by the blowpipe, or by the heat of a small furnace. The basis of all *E.* is a highly transparent and fusible glass, called *frit*, *flux*, or *paste*, which readily receives a color on the addition of metallic oxides. There is no difference between an *E.* and a glaze, save in the character of the surface to which it is applied. Both are vitrified substances, either with or without color, and exhibiting every degree of translucency,—some varieties being perfectly transparent, while others are completely opaque. Chemically they consist of easily fusible salts, such as the silicates and borates of sodium, potassium, and lead, to which various metallic oxides are added when it is desired to impart color to the *E.* These varieties of glass are pulverized, and the powder is used either in a dry or, more commonly, in a moistened state. The powder or paste, having been spread over the surface to be

incrusted, is exposed to a moderate temperature in a muffle heated in the *E*-furnace, when the vitreous substance soon becomes sufficiently fluid to spread itself over the metallic surface, to which it closely adheres. If the glass is merely cemented to the metal, without any trace of fusion, the process is not true enamelling. Popularly the term *E*. has a much wider use, being applied, in fact, to almost any brilliant surface, whether produced by varnishing, by lacquering, or by other processes not involving fusion; hence we hear of enamelled leather, enamelled paper, enamelled slate, etc. Sometimes a coating of true *E*. or of glaze is employed solely for utility, as in the case of vessels of enamelled iron or of glazed earthenware; but more commonly *E*. are applied with a view to decorative effect, the decoration thus produced being extremely permanent, since the fused material is but little affected by atmospheric influences. When enamelling is thus artistically employed, it is usual to speak of the finished works of art themselves as *enamel*s (Fr. *émaux*).

In order to prepare a plate for the artist, a thin piece of gold or of copper is carefully annealed, and then coated with a dead white *E*. The *E*. is imported in cakes from Venice, and is made from a mixture of silica, borax, and stannic oxide. After the plate has been fired, a second coating of *E*. is applied, and the plate returned to the oven. It is afterwards coated for the third time, but now with a more easily fusible glass, which is known in the workshop as "flux." This is also imported from Venice, in the form of tubes and beads, and is employed to produce a brilliant lustre on the surface. The ground having been thus prepared is carefully ground smooth, and is then ready for the artist. The colors which he employs consist of various metallic oxides mixed with the flux; but it is obvious that the enameller's palette must be limited, since he is able to employ only such substances as are permanent at the temperature to which the plate will be subjected in the muffle. Blue colors are produced by means of oxide of cobalt; violet by oxide of manganese; green by cupric oxide or by chromic oxide; reddish by cuprous oxide, which is difficult to work in the oven, or by the preparation of gold known as purple of Cassius, which also produces a fine purple; yellow by oxide of silver, oxide of lead, or an alkaline antimoniate; brown by ferric oxide; and black by ferrous oxide, or by means of cobalt and manganese, which have intense tinctorial power, and produce dense colors. Special recipes will be found in technical treatises, and need not be inserted here. The powdered colors of the enameller are mixed with oil of lavender or spike and spirit of turpentine, as a vehicle, and are applied to the *E*-ground by means of a camel's-hair pencil. After each layer has been spread over the surface the plate must be fired, and highly finished work may have to pass through the oven a score of times. Once vitrified, the colors are permanent; hence the artist has no opportunity of correcting faults, except by the tedious process of grinding away a portion of the plate. Since the tints may be greatly modified by too high a temperature, the greatest care is needed in managing the furnace. In return for the great labor and risk involved in enamelling, the artist secures permanence for his work, the painting being always as fresh as when first executed; it is indeed a painting in glass.

To whatever period the origin of enamelling may be assigned, it is certain that glazes having the composition of good *E*. were manufactured at a very early date. Excellent glazes, composed about as modern *E*., are still preserved on some of the bricks which have been found among the ruins of Babylonia and Assyria, and have been referred to the 8th or 7th century B. C. Enamelling was probably practised at a very early period in Western Europe, but it is in the Eastern empire that we find the earliest historic evidence of the art having flourished as an important industry. Byzantium was indeed for centuries the great seat of this industry, which probably dated from at least the time of Justinian. The word "smaltum" is found for the first time in a life of Leo IV. written in the 9th century. Theophilus, the artist-monk, has left a minute description of the manner in which the Byzantine enamellers of the 10th century carried on their work. Most of the Byzantine *E*. were executed on plates of gold, and

large numbers have no doubt been destroyed on account of the intrinsic value of the metal. Such specimens as are extant furnish valuable examples of what is known as the *cloisonné* process. In *cloisonné* work, the design is presented in colored *E*., which are separated one from another by means of ribs of metal bent so as to follow the outline of the subject. A plate of gold generally formed the basement of the work, and upon this plate the design was traced in slender fillets of gold. These threads were easily bent to the required form, and were fixed upright upon the plaque, so as to form a number of cells for reception of the *E*. The powdered glass, moistened into a paste, was carefully introduced into these compartments, and the prepared plate was then fired. To retain the fused *E*., the edges of the plates were slightly turned up, thus forming a rim. After careful cooling, the irregular fused surface was ground down and polished, when the design appeared in colored *E*. separated by gold partitions, or *cloisons*. In many cases the metal base forms part of the field, and the subject is then enamelled in a hollow which has been beaten out, while the gold forms a brilliant background. *Cloisonné* enamelling has been employed by the Chinese and Japanese, who, instead of restricting it to flat surfaces of the precious metals, have applied it to copper vases and other large hollow vessels. They also ingeniously attach the metal fillets to the surface of pottery, and thus produce cups, vases, and other objects in porcelain ornamented with *cloisonné* work. Many Chinese and Japanese *E*. are, however, executed by other processes, such as the *champlevé* method, to be afterwards described. — A rare variety of *cloisonné* enamelling is known to French antiquaries as *E. de pique à jour*. The peculiarity of this style consisted in setting transparent *E*. without any background, so that light could be freely transmitted through the glass, the *E*. being fixed by having their edges fused to the windows in which they were framed. Specimens of this work are extremely rare. — Very similar in effect to the *cloisonné E*., but much less rare and valuable, are those inlaid works which were executed by the *champlevé* process. Copper was usually employed in place of the precious metals; and the partitions between one color and another were formed by ridges of the base, and not by separate fillets of metal. A plate of copper, about  $\frac{1}{2}$  inch thick, and having the surface polished, formed the groundwork of the *E*. By means of a graver, the parts to be enamelled were chased out, so as to leave slender ribs standing up as boundary walls to the cavities. *E*. in the state of either powder or paste was then introduced into these casements, and the work was fired. Finally, the surface was polished, and the metallic outlines generally gilt. In some examples, the figures are represented in *E*. on a metal background; while in others the figures stand out in engraved metal upon an enamelled background; and in others again the entire field is enamelled. — Soon after the introduction of transparent enamelling in Italy, the art became popular in France, and this probably led the way to the invention of *enamel-painting*. The artists of Limoges acquired great celebrity in this work. The early painted *E*. from the Limousin workshops were executed in opaque white upon a brown ground, the white being overlaid where necessary by transparent colored enamels. The lights were picked out in gold, while the brilliant effect of gems was obtained by the use of *paillettes*, or colored foils. Nardon Penicaud is the best-

known artist in this style, and an excellent example of his work, dated 1503, is preserved in the Hôtel de Cluny in Paris. About the beginning of the 16th century a much more finished style of painting was introduced at Limoges; and under the auspices of Francis I. the art attained to a considerable development. Léonard Limousin, who is known to have painted from 1532 to 1574, became the great master of this style. While some of the works were executed in brilliant colors, most of them were in monochrome. The background was generally dark, either black or deep purple, and the design was painted *en grisaille*, relieved in the case of figure-subjects by delicate carnations. The effect was occasionally heightened by appropriate touches of gold, and in many of the colored *E.* brilliancy was obtained by the use of silver foil, or *puillon*, placed beneath a transparent *E.* Portraits were frequently painted on copper plaques; and the art was also applied to the decoration of ewers, vases, plateaux, candlesticks, salt-cellar, and a variety of elegant objects for domestic as well as ecclesiastical use. Among the artists of this school may be mentioned Pierre Raymond, Jean Pénicaut, Pierre and Jean Courtois, Martin Didier, Jean Court dit Vigier, P. Courteys, and the master known only by his initials C. N. Towards the latter end of the 16th and in the beginning of the 17th century it was the fashion for the Limoges enamellers to paint in a minute style, which is seen in the works of the brothers Laudin and of the family of Nouailhers. The art at length degenerated into a system of tawdry coloring, and in the reign of Louis XIV. it fell into a state of decay, from which an attempt to revive it was made by Louis XVI., but without success.—Probably the decline of the Limoges school was connected with the rise of a new branch of enamelling, which has been distinguished as the *miniature style*. This is the style which has continued in vogue up to the present day.—In the middle of the last century the art of enamelling was largely applied to the decoration of snuff-boxes, patch-boxes, tea-canisters, candlesticks, needle-cases, labels for wine-bottles, and a variety of other small articles. The objects were usually made of copper, and having been coated with an opaque white *E.*, were decorated with Watteau subjects and floral and other designs, painted in enamel colors. Advantage was also taken of the process of transferring engravings from copper plates to glazed surfaces,—a process which was introduced about the year 1750 by Sadler and Green of Liverpool, and was largely employed for the decoration of pottery and porcelain. Splendid snuff-boxes and other ornamental articles in enamelled work were also turned out by artists in France and Germany.

*Enamelling of cast-iron.* The art of enamelling has been of late years extensively applied to the coating of iron vessels for domestic purposes, with the view of keeping a clean surface and preventing the rusting of the metal, and within the last forty years a large number of patents have been granted for similar purposes. One of the most extensively used processes is that of Charles Henry Paris, which is now largely worked at Birmingham. The metal articles are first cleaned with dilute sulphuric acid, and powdered glaze is then sifted upon the clean surface. Adhesion of the powder is secured by applying to the iron a coating of gum-water. The object is then dried in an oven, whence it is transferred to the enamelling-furnace, where it is heated until the fused glaze flows evenly over the surface. After removal from the

oven, the objects are allowed to cool with extreme slowness. It is often found necessary to apply a second coating of *E.* Paris's composition consists of 130 parts of cullet or broken glass, 20½ parts of carbonate of sodium, and 12 parts of boracic acid. This forms the fundamental glaze, upon which variously colored *E.* may be employed. If enamelled vessels are to be used for culinary purposes, great care must be taken that the glass contains no lead, the presence of which would be highly dangerous. Acids often find their way through the pores of an *E.* to the subjacent metal, and spreading out between the iron and the glaze cause the *E.* to peel off. Exposure to sudden changes of temperature also tends to injure the *E.*—Enamelling of a similar character is now largely used for street plates, name-plates at railroad stations, advertising tablets, and other objects where permanent lettering is required. The insides of baths, cisterns, and boilers are also protected by enamelling, and it has been proposed to prevent the fouling of ships' bottoms by a coating of *E.* *Imp. duty, E.* of glass and oxide of iron, 40 per cent.

**Enamelled Cards**, pieces of pasteboard, one surface of which has been coated with white lead and size, and then glazed by passing between highly polished rollers.

**Enamelled Leather**, glazed leather for patent boots and shoes, belts, etc., by means of sumach. The gloss, or enamel, is given by successive coats of linseed oil, and finally of a varnish of copal and asphaltum. See LEATHER.

**Enamel-Painting.** See ENAMEL.

**Enamel Ware**, iron cooking utensils, the interior surfaces of which are enamelled. See EX-AMEL.

**Encaustic**, an ancient method of painting, in which the pictures were executed with wax colors, and finished by the application of a hot iron. The term is now very generally applied to all kinds of painting, where the colors are laid on or fixed by heat, so as to be rendered permanent and brilliant.

**Encaustic Tile**, a variegated paving-tile, on which patterns have been formed in colored clays on the ordinary buff-tile, and fired, which brings out the colors more vividly. This art appears to have had its origin in the latter part of the 12th century, but the culminating point of its excellence and popularity was attained during the 13th; and it was extensively used for the decoration of Gothic buildings in connection with each succeeding change in that style of architecture. The modern revival of the art dates from the year 1830, when a patent was granted to Samuel Wright, an English potter, who sold his patent-right, in 1844, in equal shares, to the celebrated china manufacturer, Herbert Minton, and Mr. Fleming St. John. *E. T.* have been since largely manufactured at Stoke-upon-Trent, and at Benthall, near Brosely, Shropshire, England. The modern application of *E. T.* is by no means confined to the ecclesiastical purposes for which they were mainly used in mediæval times, although for this purpose many of the ancient designs have been reproduced, and the rough execution of the old examples has been imitated with striking fidelity. Some of the most eminent architects of recent years have exercised their skill in the production of designs more suitable for domestic purposes; and pavements of these tiles, combined with other kindred manufactures, have become an almost universal part of the permanent decoration of the better class of public and private buildings,

for which purpose they are largely imported into this country, already partly superseding the perishable forms of flooring, and at the same time rendering unnecessary any decorative coverings. *Imp. duty, 35 per cent.* See MOSAIC and TILE.

The manuf. of *E. T.* may be described under two heads, — viz., the *plastic* and the *semi-dry or dust* processes. The former, which was the only one employed up to the year 1823, is in every essential point the same as that used in mediæval times, differing merely in the greater finish and perfection which modern appliances have effected, and probably also in the material of the moulds. It is not known of what those anciently used were made, but conjecture has suggested wood, fired clay, and stone. The great difficulty of the manuf. consists in the necessity for introducing into a single tile the variety of different colored clays or *bodies* which together compose the design, it being essential that they should not only be perfected by the same amount of heat in the process of firing, but that they should possess an equal contractile power during each stage of the manufacture. The tile is first impressed from a plaster of Paris mould, bearing the pattern in relief, and set in a brass frame, upon which fits another frame, the dimensions and depth of which correspond with the size and thickness of the tile; the pattern is thus sunk in the clay to a depth of about one sixteenth of an inch, in the following manner. The workman first introduces into the mould what may be described as a sheet of refined clay of the desired color for the ground of the pattern; upon this facing, which forms a kind of veneer, is placed a thicker mass of a coarser kind of clay, and the whole is then subjected to screw pressure, which consolidates the two kinds of clays, and at the same time perfectly impresses the pattern of the mould; the superfluous clay is then removed with a scraper, and a second veneering of fine clay, similar to that used for the face, is placed on the back; the tile being removed from the mould, the depressed parts of the design are filled with clay, of one or more colors, by pouring it in in a *slip* or semi-liquid state. The tile is then set aside for twenty-four hours to stiffen, and when the slip infill has become nearly of the same consistency as the tile itself, the face is brought roughly to an even surface, by "spreading" the soft clay with a palette-knife. The tile is then further allowed to dry till it attains the stiffness of wax, when it is "finished" by scraping the face with a steel scraper, until the insid pattern and ground are developed free from superfluous clay, and the edges are cut true in a square, when it is ready for the drying-store. When the drying, which takes from six to ten days, is completed, the tiles are placed in fire-clay boxes, known as *sizzers*, containing from eight to ten each, which are then stacked, one upon another, in the kiln or oven. The process of firing occupies four days and nights, and has to be conducted with the greatest care, as not only the exact size and hardness of the tiles are dependent upon it, but also the perfection of the colors, with which object it is necessary to raise the heat very gradually, and to secure a regular circulation of air in the oven, so as to produce the exact degree of oxidation needed to bring out the desired colors in the materials used for this purpose. The pyrometers used in this part of the process consist of long narrow tiles, and the degree of heat is judged both by their color and the gradual reduction in length which they undergo, each piece, as it is withdrawn from the oven, being measured in a gauge, with this object, — the total shrinkage of the tile, in the drying and firing, amounting to about 1½ inches in the foot. For purposes of paving, most of the modern *E. T.* are used in the *bisque* or unglazed state, the glaze in the ancient tiles having apparently been employed with the object of covering the soft material of the tile itself, and of adding richness to the color. Where glazing is found necessary in the modern tiles it is effected by dipping them in a combination of lead, alkaline salts, feldspar, and silica, finely levigated in water, which is fused by passing them through a kiln specially constructed for the purpose.

The *semi-dry or dust* process of manuf. *E. T.* is an adaptation of an invention patented in the year 1840 by Richard Prosser, by which articles of various kinds are moulded out of *pulverized clay*, in metal dies, by screw pressure. In the year 1853 Messrs Boulton and Worthington, engineers of Burslem, patented a process by which the use of powdered clay (hitherto only used for tiles of one color) was applied to the manuf. of *E. T.* The design is formed by perforated brass plates, — from one to six or seven being used according to the nature of the pattern. Where the whole design can be perforated in the plate without detaching such parts as would represent the ground, only one plate is needed, but where there are several concentric rings or similar forms, additional plates are required. Into the perforations of each plate metal rams, attached to a flat plate of iron, are accurately fitted. The metal die in which the tiles are pressed is composed of a thick block and a square frame or "box", the latter is connected with levers and a balance-weight, so that it can be raised or depressed, either forming a hollow mould, of which the face of the block above mentioned forms the bottom, or depressed in such a way as to leave the face of the block standing above it, in which latter position it is ready for the commencement of

the process. The perforated plates first mentioned are then, in succession, placed upon the face of the block, being kept in position by two pins fixed to the frame of the die, corresponding with holes made in their margin. The perforations of the brass plate being filled with powdered clay of the desired color, this is so far compressed, by means of the metal ram, as to allow both the ram and the plate to be removed together, leaving the compressed dust (representing the pattern of the tile in relief) on the block or face plate. In cases where a number of plates are necessary, the pattern is thus *built up*, each adding such a part as can be perforated in a single plate. The frame is then raised, so as to form a mould of the required depth, which being filled with powdered clay, intended to form both the ground of the pattern and the substance of the tile, the whole mould or die is slid, in a groove provided for the purpose, under the screw press, to which is attached a plate covering the mould, and resting on the top of the movable frame; this, on pressure being applied, forces down the frame until the powdered clay is thoroughly consolidated and incorporated with that part forming the design. On the pressure being relieved, the die is drawn from beneath the press, the frame is forced down by means of the levers to which it is attached, and the tile is left resting face downwards on the block, when it is ready for the drying-store, the subsequent treatment being the same as in the plastic process. This process affords the advantage of much greater rapidity in execution than can be effected by the plastic method, and as the tile undergoes little or no shrinkage in the desiccation of the small amount of moisture which is needed to make the particles of the dust combine under pressure, the risk of distortion in the process of drying is reduced to a minimum, but the heavy prime cost of the perforated brass plates necessarily confines this otherwise valuable invention to such designs as are most largely in demand.

**Enchasing.** See CHASING.

**Enchère** [Fr.], an auction; an outbidding.

**Enclosure**, land fenced in or hedged round for separation or for the protection of crops.

**Encre**, the French word for printing or writing ink.

**Encyclopædia**, a dictionary or descriptive work of reference, which treats of the various branches of the arts, sciences, and manufactures.

**Endasse, Endraze**, names for the short ell or pike in Turkey, by which cotton goods and carpets are measured; it is equal to 27.06 inches.

**Endive**, a hardy annual herbaceous plant, the *Cichorium endivia*, the blanched leaves of which are used as a salad.

**Endless Screw.** See SCREW.

Fig. 163 — ENDOSMOMETER.

**Endorsement.** See INDORSEMENT.

**Endosmometer.** When two different liquids are separated by a thin porous partition, either

inorganic or organic, a current sets in from each liquid to the other; to these currents the names *endosmose* and *exosmose* are respectively given. These terms, which signify *impulse from within*, and *impulse from without*, were first introduced by M. Dutrochet, who first drew attention to these phenomena. They may be well illustrated by means of the *endosmometer*. This consists of a long tube, at the end of which a membranous bag is firmly bound (Fig. 163). The bag is then filled with a strong sirup, or some other solution denser than water, such as milk or albumen, and is immersed in water. The liquid is found gradually to rise in the tube, to a height which may attain several inches; at the same time the level of the liquid in which the endosmometer is immersed becomes lower. It follows, therefore, that some of the external liquid has passed through the membrane and has mixed with the internal liquid. This phenomenon is due to the attraction which the two liquids have for each other and for the diaphragm separating them, and advantage is taken of it in many operations of the chemist.

**Endowment**, in life insurance, is a term applied to the assurance of a capital sum or survivorship of time.

**Enema**, a medicine, usually liquid, but sometimes gaseous, thrown into the rectum or lower bowels; a clyster.

**Enflourage**. See POMADE.

**Engagement**, an obligation, contract, or undertaking entered into.

**Engine**, the general name for any mechanical machine which produces or regulates motive-power, such as fire-*E.*, steam-*E.*, etc. An *E.* acts automatically, so differing from an ordinary *machine*, whose motor is distinct from the operator, and from a *tool*, which is propelled and operated by one person. *E.* are of three great classes, locomotive, marine, and stationary, and in their motion are either oscillating or rotary.

**Engineer**, one skilled in mechanism, or the construction or management of complicated machinery, and the uses of motive-power, repairs of mill-work, etc. See ENGINE-MAN, and ENGINEERING.

**Engineering**, the art of designing and constructing works, embraces a very wide range of subjects, and the different departments into which the profession is now divided do not admit of very strict definition; but it may be mentioned that *civil E.* includes the design and construction of canals, river navigation, harbors, docks, roads, bridges, railroads, lighthouses, water-supply, irrigation, sewerage, gas-supply, telegraphs, etc.; *mechanical E.* includes machinery, mill-work, steam-engines, iron ship-building, agricultural implements, etc.; *mining E.* includes the working and raising of coal, iron, lead, copper, and other minerals; and *military E.* includes fortifications, gunnery, artillery, telegraphy, etc., as applied to warfare.

**Engine-Man**, a machine-man; one who attends to the engine in a locomotive, steamboat, mill, etc. He is often loosely called an engineer.

**England**. See GREAT BRITAIN.

**Engrais**, the French word for manure.

**English**, in printing, a size of type between great primer and pica.

**English Channel** [Fr. *La Manche*, the sleeve], is that part of the Atlantic Ocean which lies between the N. W. coast of France and the S. coast of England. Its eastern extremity is connected with the German Ocean by the Strait of Calais, 21 m. wide, and on the west it is imperceptibly

confounded with the Atlantic Ocean. It lies between lat. 38° 48' and 51° north, and long. 1° 20' east and 5° 43' west. At its termination—on a line drawn from Land's End to the extreme easterly point of the department of Finisterre in France—it is about 100 m. wide. On the French coast it forms three considerable bays; the most easterly receives the Severne; the second receives the Seine and several smaller rivers; the third and largest lies on the S. W. of the peninsula of Cotentin. On the English coast is Mount Bay, between Lizard Point and Land's End. Between Lizard Point and Start Point is a large gulf, on which are situated Talmouth and Plymouth; the Gulf of Exeter lies to the E. of Start Point. The principal islands in the English Channel are, the Isle of Wight, on the English coast, and the Norman Islands, lying on the French coast, the principal of which are Guernsey and Jersey. The prevailing winds are from the west. The channel, being shallow and confined, is subject, from its communication with the Atlantic, to high and impetuous tides. The channel has a current that sets from the westward, and is noted for its disagreeable roughness. Portions of the channel are of dangerous navigation, but chiefly near the shores.

**Engraving** is the art of producing by incision or corrosion designs upon blocks of wood, plates of metal, or other materials, from which impressions or prints upon paper or other soft substances are obtained by pressure. There are several varieties of *E.*, the chief of which are: 1. *Line E.* on metal plates, usually of copper or steel, in which the line is always incised; 2. Etching, usually on metal, in which the lines are corroded by means of acid; 3. Mezzotint, in which there are no lines whatever, but only shades produced by roughening the surface of the metal; 4. Woodcut, in which the lines which print black have to be left in relief, while the surface round them is cut away. These primary technical conditions have an irresistible influence even upon the mental qualities exhibited in the different kinds of *E.* Each kind is favorable to certain mental states, and unfavorable to others, each being in itself an artistic as well as a technical discipline. A line *E.* will not see or think like an etcher, nor an etcher like an *E.* in mezzotint; and the consequence of this difference is that the manner in which a line has been cut has a great influence in determining the direction of artistic taste and feeling. Nor is that influence confined to the engravers themselves. The enormous multiplication of their work by printing makes engravers only second to writers in their power over public taste, which they can refine or vitiate by spreading refined or vulgar interpretations of pictures. The several varieties of *E.* are given in this work under the headings COPPER-PLATE ENGRAVING, ETCHING, LITHOGRAPHY, MEZZOTINT, NIELLO, WOOD-ENGRAVING, etc.

**Engravings**, impressions taken on paper from engraved steel or copper plates; in trade, lithographic prints are generally classed with engravings. *Imp.* duty, bound or unbound, in black or colored, 25 per cent.

**To clean E.** Place the *E.* on a smooth board, and cover it thinly with finely powdered and very clean common salt. Next squeeze lemon juice upon the salt so as to dissolve a considerable portion of it. Now elevate one end of the board so that it may form an angle of about forty-five or fifty degrees. Next pour on the *E.* boiling water from a tea-kettle until all the salt and lemon-juice are washed off. The *E.* will then be found to be perfectly clean and free from stains. Care must be taken to dry it on the board or on some smooth surface

very gradually. It will acquire a yellow tint if dried by the sun or before a fire.

To *mount E.* Strain thin calico on a frame, then carefully paste on it the *E.*, so as to be free from creases; afterwards, and when dry, give the *E.* two coats of thin size (made by putting a piece of glue the size of a small nut into a small cupful of hot water); finally, when this dries, varnish the *E.* with a varnish known as "white hard."

**Engrossing**, the art of making a fair copy of a draught in a bold plain hand.—The purchasing of large quantities of any commodity, in order to sell it again at a high price.

**Enrichment**, the builder's name for the figuring or moulding of a cornice.

**Enrolment of Vessels.** See COASTING-TRADE.

**Ensign**, a banner usually suspended over the poop or stern of a ship, to distinguish vessels of different nations.

**Enter**, to register; to set down in writing.—To lodge a manifest and make entry of goods at the custom-house.

**Enterprise**, a projected scheme; a hazardous adventure.

**Entertainment**, a public dinner; amusement of any kind, a concert, dancing-room, etc.

**Entire**, the name for a kind of beer, combining the appreciated properties of two or three esteemed qualities of malted beverage.—A stallion or ungelded horse.

**Entracte** [Fr.], the time between the acts of a play; an interlude.

**Entrée**, an admission or introduction.—The first course of dishes.

**Entrelacs** [Fr.], threads, twine, or string.

**Entremets**, side-dishes; dainties.

**Entrepoter** [Fr.], to store or warehouse goods.

**Entrepot**, a mart; a store-room for the deposit of goods; a bonded warehouse.

**Entrepreneur**, a French contractor; one who executes or undertakes constructive works.

**Entresol** [Fr.], a suite of rooms between two floors; a low apartment, usually placed above the ground-floor.

**Entry**, the record made in a merchant's books of any business transacting. See BOOK-KEEPING.—The lodgment of a ship's papers in the custom-house on arrival, when permission to land cargo is obtained. See IMPORTATION.

**Enumerator**, a calculator; one employed to count over or reckon up figures or things.

**Envelope**, the outer cover or enclosure case for a letter; the wrapper on which the address is written.

*E. machine.* It was at the London Exhibition of 1851 that the public first became generally acquainted with the beautiful machines for making *E.* Since that time such machines have been constantly in use, bringing down the price of *E.* in a wonderful degree, and yet leaving a large amount to be executed by hand-making. Nearly all the processes are automatic in their nature, and the apparatus. The paper is cut into blanks; the seal flap is stamped with some kind of device by a die; a plunger in a box makes four creases in every blank; two flaps are folded down by two levers; gum is applied to each flap edge; a lever folds down a third flap on these two edges, to which it is instantly cemented; another lever folds down the fourth flap, but without cementing it; and then a pusher drives away the finished *E.* to make room for another. All these processes succeed one another with such beautiful regularity that the *E.* are precisely alike (until a purposeful change is made in form, size, or pattern) and with such rapidity that an *E.* is completely made in less than a second, or about 4/100 per hour by one machine. The Raymond's, Robinson's and Roumestan's, and Keating's, are also well-known *E. machines.*

**Eosine**, a recently discovered aniline red color resembling cochineal in its qualities. See DYEING (*aniline reds upon wool*).

**Epaissieur** [Fr.], thickness; density.

**Epaulet**, an ornamental badge, worn on the shoulder of military men. The *E.* of commissioned officers are usually of gold, while those worn by non-commissioned officers, etc., are of brass, worsted, etc.

**Epaves** [Fr.], goods found floating at sea without owner; flotsam and jetsam.

**Epergne**, an ornamental stand for a large dish on a table.

**Epicerie** [Fr.], grocery wares, spices, etc.

**Epidemic**, common to many people. An epidemic disease (*epidemic*; *epidemy*) is one which seizes a number of people at the same time and in the same place, but which is not dependent on any local cause, but on some extraordinary condition of the air. When a disease is peculiar to a people or nation, and appears to depend on local causes, it is said to be *endemic*. Thus, Asiatic cholera may be taken as an example of the first, and the agues of low countries as examples of the other.

**Epingle** [Fr.], a pin; any small pointed instrument.

**Epitome**, an abstract, abridgment, or compendium.

**Epizootic Diseases** are diseases which attack different species of domestic animals in the same manner that epidemics do man. These maladies ravage large tracts of country, frequently causing great mortality amongst the various animals inhabiting the localities visited by them; different animals being assailed by different forms of *E. D.* For instance, there is the rinderpest, or plague peculiar to cattle; the typhoid or gastric fever of horses; the small-pox of sheep; the diphtheria, affecting oxen, sheep, goats, and pigs; the influenza of horses; and the charbon of pigs. Dogs, cats, tame and wild birds, fish, silk-worms and bees, each suffer from a special variety of *E. D.*

**Eprouvette**, a French instrument for testing the strength of gunpowder.

**Epsom-Salts**, or **Epsoms**, the sulphate of magnesia, a salt, when pure, usually found in colorless acicular crystals derived from the right rhombic prism, and containing 51.22 per cent of water of crystallization. It is somewhat efflorescent, for at 32° F. water will dissolve over one fourth its weight of the anhydrous salt, and as the temperature is raised the solubility increases. The salt was formerly manufactured from the waters of the mineral spring of Epsom, England. It also exists largely in sea-water, from which it was formerly prepared in large quantities. In Italy it is now prepared from a schistose rock; in England, from dolomite; in Pennsylvania and Maryland, from magnesite. This salt is used in medicine as a cooling and generally safe cathartic. It is nauseous to the taste, but may be easily taken in "soda-water" with lemon sirup. In the household it is an excellent addition to starch, decidedly increasing its stiffening powers. Mixed with ordinary whitewash, it gives a fine pearly whiteness to walls. It is largely used for weighting cotton cloth. As a manure it has been chiefly employed as a top-dressing for clover hay.

**Equation of Payments.** When several sums of money due at different times are owing from one person to another, it is sometimes required to find the time when they may be all discharged in one payment without injury to either party: this is called *equating the payments*; and the principle of the rule consists in finding the time when the interest of the sums which are deferred till after they are due is equal to the discount of those which are paid before they are due.

## 1. RECKONING SIMPLE INTEREST.

**Rule.** — Multiply each sum by the time when it is due, then divide the sum of these products by the total debt; the quotient is the time at which all the money ought to be paid.

**Example.** — A sum of \$300 is due on 21 March, \$350 on 18th March, and \$525 on 17th April; required an average time for the payment of them all in one sum.

The number of days from the 2d to the 18th of March is 16; and from the 2d March to the 17th April, 46; hence,

$$\begin{array}{r} 300 \times 0 = 0 \\ 350 \times 16 = 5,600 \\ 525 \times 46 = 24,150 \\ \hline 1,175 \quad . \quad 29,750 \end{array}$$

25 days from March 2d, or March 27th nearly.

The distance of time is calculated from the 2d March, because, the first sum becoming due on that day, there is no discount to calculate upon it.

## 2. RECKONING COMPOUND INTEREST.

**Rule.** — From the logarithm of the sum of all the debts subtract the logarithm of the sum of the present values of such debts, and divide the remainder by the logarithm of the amount of £1 in a year, at the given rate of interest: the quotient will be the equated time required.

**Example.** — Suppose A were indebted to B in the sum of \$750, which was to be paid in three instalments; namely, \$250 at the end of 1½ years, \$100 at the end of 2 years, and the remaining \$400 at the end of 4 years; in what time, reckoning compound interest at 6 per cent, ought the whole to be discharged in one payment?

Here we have the sum of all the debts = 750, and the sum of their present value = 634.913963 (See INTEREST and ANNUITIES.) Consequently,

$$\frac{\text{Log. } 750 - \text{Log. } 634.913963}{\text{Log. } 1.06} = \frac{.723463}{.0253959} = 285887, \text{ or } 2 \text{ years and } 513 \text{ days}$$

**Equations (Rule of).** See CHAIN-RULE.

**Equator**, a great circle of the sphere, equally distant from the two poles of the world, or having the same poles as the world. It is called *E.* because when the sun is in it the days and nights are equal; whence also it is denominated the *equinoctial*; and when drawn on maps, planispheres, or globes, it is called the *equinoctial line*, or simply the *line*. Every point in the equator is 90 degrees, or a quadrant's distance, from the poles of the world, and hence the equator divides the sphere into two equal hemispheres, in one of which is the northern, and in the other the southern pole. Terrestrial longitudes are measured on the equator or some one of its parallel circles; commencing from some arbitrary point, which different nations assume variously, most of them adopting the meridian which passes through their capital city or principal observatory. Latitudes are counted from the equator along the meridian.

**Equatorial**, an astronomical instrument with a telescope, for taking celestial observations.

**Equestrian Statue** is a statue representing a person mounted on horseback.

**Equinox** is the time at which the sun passes through the equator in one of the equinoctial points. When the sun is in the equator, the days and nights are of equal length all over the world, whence the derivation of the term. This happens twice every year, namely, about the 21st of March and the 22d of September; the former is called the *vernal*, and the latter the *autumnal* equinox. The equinoxes do not divide the year into portions of equal length; for in consequence of the sun being at his greatest distance from the earth during the summer months, and his angular motion in his orbit being consequently slower, the interval from the vernal to the autumnal equinox is greater than that from the autumnal to the vernal. In other words, the sun continues longer on the northern than on the southern side of the equator. At the beginning of the present century the difference amounted to 7 days 16 hours and 51 minutes. The summer in the northern hemisphere

is constantly longer than in the southern by this quantity; and to this circumstance some meteorologists ascribe, in part at least, the higher temperature that is found to prevail in the northern hemisphere under the same parallel of latitude.

**Equipage**, the furniture of an army or body of troops. In this sense it includes arms, artillery, utensils, provisions, etc. Camp *E.* includes tents and things necessary for accommodation in camp; while field *E.* consists of arms, artillery, wagons, tumbrils, etc. — *E.* is also often applied in Europe to a vehicle or carriage of state.

**Equipments**, the clothing, accoutrements, arms, etc., of a soldier; hence there are artillery *E.* for field and garrison, and engineer *E.*, etc.; also the fitting out of a ship for sea.

**Equitable Fire and Marine Insurance Co.**, located in Providence, R. I., organized in 1859. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$200,000; net surplus, \$67,138.61; total cap. and surplus, \$267,138.61; risks in force, \$9,025,880; premiums, \$102,693.81; premiums received since the organization of the Co., \$1,503,855.71; losses paid, \$1,145,038.85; cash dividends paid to stockholders, \$274,000.

**Equitable Life Insurance Society of the U. S.**, located in New York City, and organized in 1859. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$100,000; total net assets, \$35,015,675.93; liabilities, \$28,526,888.64; gross surplus, \$6,488,787.29; new policies issued in 1878, 5,071, amounting to \$15,570,355; old policies revived during 1878, 1,044, amounting to \$5,869,858; total policies in force at the end of the year, \$46,383, amounting to \$157,737,356; received for premiums and annuities in 1878, \$6,543,750.53; total paid policy holders for losses, matured endowments, annuities, etc., in 1878, \$4,935,171.43.

**Eraser** is a knife with a cordate blade, sharpened on each edge, and adapted for erasing marks from paper by an abrading or cutting action, according to the angle at which it is held.

**Erect**, to raise or build up, as a house, pier, etc.

**Ergot, or Spurred Rye** [Fr. *ergot*, a cock's spur; Ger. *Mutterkorn*], the diseased seeds of *Secale cereale*, or common rye, produced by the attacks

Fig. 164. — ERGOT OF RYE.

of a fungus, which, taking possession of the ovary, destroys it, producing in its room a long, black, hard, hornlike body (Fig. 164). *E.* is remarkable for its specific stimulating effects upon the uterus, and is much employed in cases of difficult parturition. It deteriorates greatly by age, being subject to the attacks of a description of acarus resembling the cheese mite, but much smaller, which destroys the whole of the internal portion of the grain, leaving nothing but the shell and a considerable quantity of excrementitious matter. To prevent this the *E.* should be well dried, and then placed in bottles or tin canisters, and closely pre-

served from the air. The addition of a few cloves, or drops of the oil of cloves, or strong acetic acid, or a little camphor, will preserve this substance for years in close vessels. *Imp. free.*

**Erie**, a city and port of entry, the capital of Erie Co., Pennsylvania, is situated on Lake Erie, opposite Presque Island, about 120 m. N. of Pittsburgh, lat.  $42^{\circ} 8' N.$ , lon.  $80^{\circ} 10' W.$  It is very nearly equidistant from Cleveland and Buffalo on the Lake Shore R.R., which gives communication E. and W., and is the northern terminus of the Philadelphia and Erie R.R., which penetrates the lumber-region of the State, and also gives connection with Harrisburg and Philadelphia and the anthracite coal-fields. Erie is also the northern terminus of the Erie and Pittsburgh R.R., which passes through the bituminous coal-regions. Its inhabitants are engaged chiefly in various kinds of iron manufacture, and it possesses large rolling-mills. It has also leather manufactories, a brass foundry, petroleum refineries, and several large breweries. For many of its manufactories a large supply of water is required, and this is supplied from Lake Erie by powerful engines which force it to the top of a tower 200 feet high, whence it is distributed through the mains. The harbor, which is formed out of the natural bay, protected by a breakwater, is  $\frac{3}{4}$  m. long, more than 1 m. wide, and from 9 to 25 feet deep. The principal shipments are coal, iron, and petroleum; and the total value of imports from Canada for the year 1878 was \$70,801, and of exports, \$55,671. The Pennsylvania R.R. Co. runs a line of first-class propellers between this port and the upper lakes, and over 50 sailing vessels are owned here. Pop. about 25,000.

**Erie and Pittsburgh R.R. Co.** runs from New-castle to Girard, Pa., a distance of 81 m., with a branch from Dock Junction to Erie Dock, 3.47 m. This Co., whose offices are in Erie, Pa., was chartered in 1858. The road was open in 1865, and in 1870 it was leased for a term of 999 years to the Pennsylvania R.R. Co., which now operates it, for a rental of 7% on stock and bonds. *Financial statement:* Cap. stock, \$1,908,400; funded debt, \$3,322,000, consisting of 1st mortgage, 7% 20 year bonds, payable in 1882, \$291,700; 2d mortgage, 7% 25 year bonds, due 1898, \$2,193,000; equipment mortgage, 7% 30 year bonds, due 1900, \$745,000.

**Erie Canal.** See CANAL.

**Erie (Lake)**, one of the five great lakes drained by the St. Lawrence, lies between lat.  $41^{\circ} 22'$  and  $42^{\circ} 52' N.$ , and lon.  $79^{\circ}$  and  $85^{\circ} W.$ , having N the fertile peninsula of Ontario, Canada, and S and E. the States of Ohio, Pennsylvania, and New York. Its shape is elliptical; length S. W. to N. E. about 265 m.; breadth varying from 10 m. to about 65 m. in the centre. It receives near its W. extremity the superabundant waters of the upper lakes by the Detroit River, its own surplus waters being conveyed to Lake Ontario by means of the Niagara. Its mean height above the level of the ocean is estimated at 565 feet, being about 52 feet below that of lakes Michigan and Huron, and 322 feet above that of Lake Ontario. Its depth, which is less than that of any of the other great lakes of the St. Lawrence basin, is nowhere more than 312 feet, and in most parts is considerably under 200 feet. Its N. shore is rocky and dangerous; the opposite one has also long lines of rock. In addition to other impediments to navigation, a current, not perceptible in the other great lakes of the St. Lawrence system, sets constantly W., and S. W. or S. W. winds continually prevail; besides which, in consequence of its shallowness, a part of the lake is frozen over every winter, and traffic on it

is obstructed by ice for some weeks in the spring after the navigation of the other lakes is open and unimpeded. Except the Detroit, Lake Erie receives few rivers of any consequence, and all, without exception, have bars at their mouths. The Onse or Welland, which unites with its E. extremity, is its principal affluent, and has been taken advantage of for the construction of the Welland Canal, of which it forms a part, connecting the lakes Erie and Ontario, and avoiding the Falls of Niagara. This lake is very important as a channel of trade and steam navigation. It is liable to violent storms, which sometimes cause disastrous shipwrecks. The chief cities on its shores are Buffalo, Cleveland, Toledo, Erie, and Sandusky, which have good harbors.

**Erie R.R.** See NEW YORK, LAKE ERIE, & WESTERN R.R.

**Eriometer**, an instrument for measuring the diameter of minute particles and fibres, as wool, by ascertaining the diameter of any one of the series of colored rings which they produce.

**Ermine** [Fr. *hermine*; Ger. *Hermin*; It. *ermellina*; Russ. *gornostai*], a species of weasel (*Mustela candida*), about the size of a squirrel, abundant in all cold countries, particularly Russia, Norway, Lapland, etc., and producing a most valuable species of fur. In summer the *E.* is of a brown color, and is called the *stoat*. It is in winter only that the fur has that beautiful snowy whiteness and consistence so much admired. The tip of the tail is always of a brilliant shining black. It is used for ladies' winter apparel, and in Europe for the robes of kings, nobles, and judges. When made up the tails are inserted one to each skin, at regular distances and in the quincunx order, or otherwise, according to the wearer's rank. The *Tutorius maculoracensis* and other N. American white weasels are properly classed as *E.*, having white winter fur and the tip of the tail black, but their fur is inferior to that of the Russian *E.* Most of the so-called *E.* fur of commerce is simply white rabbit fur, with spots of black rabbit fur inserted. *Imp. duty, see furs.*

**Errand-Boy**, a lad kept to deliver messages, or to do jobs of all kinds.

**Errata**, a published list of misprints, or typographical errors, which have escaped the eye of the author and the press reader.

**Erhines**, sternutatories; medicines which cause sneezing or mucous discharges when snuffed up the nose.

**Eruginous**, green with a blue tint, the color of verdigris.

**Esame. Esclame** [It.], a swarm of bees.

**Escapement**, in a clock or watch, is an apparatus for converting a *continuous* into an *intermittent* or *oscillatory* motion, which can more readily be made isochronous, or equal timed. A watch or clock always travels by leaps (made audible by the ticking), or alternate movements and stoppages. A small piece of metal called the *regulator* oscillates in a regular manner by a series of jerks; these jerks are manifested in the jerking movements of the seconds-hand. The *E.* is the apparatus which connects the regulator with the train of wheels. — In the common *vertical E.* for a watch or time-piece, the regulator is a horizontal wheel called the *balance*, which oscillates on a vertical axis. The axis or *vege* of the balance carries two small *pallets*, which catch into the teeth of a vertical *scape-wheel*. The *main-spring*, acting through the medium of the train of wheels, causes the teeth of the *scape-wheel*, one by one, to be caught by the *pallets*, and gives an oscillatory movement

to the balance.—The *anchor E.* (Fig. 165) is the one most commonly in use for both clocks and watches. It is so called from its resemblance to the

Fig. 165. — ANCHOR ESCAPEMENT.

flukes of an anchor, the shaft of the anchor in the clock being parallel to the pendulum and connected with it. The *E.*-wheel is a spur-wheel. The pallets projecting from the extremities of the anchor flukes alternately catch into the teeth of a wheel, producing equidistant stoppages nearly like those just mentioned. The extremity of the pallet is inclined in such a manner that, as the tooth escapes, it gives impulse to the pendulum. As, after the pallet first engages a tooth, the swing continues for some time in the same direction, anchor *E.* are of two kinds, according to the manner of their action upon the train during this swing. In Hooke's *E.* the surfaces of the pallets are so inclined that by their pressure on the tooth they turn the train slightly backward, or cause it to *recoil*, up to the end of the swing. In the *dead-beat* escapement, invented by Graham early in the last century, the surfaces of the pallets are circular arcs, having the centre of motion for their centre, so that during the swing the train simply stands still. Though the *dead-beat E.* is now generally used in clocks, there are not wanting those who prefer the recoiling *E.* Besides the anchor *dead-beat*, there are several other very ingenious forms, among which may be mentioned Lepante's *pin-wheel E.*, McDowall's *ruby-disk E.*, and Denison's *three-legged dead E.*—The *cylinder E.* (Fig. 166), which is used for watches, is so called because a hollow cylinder of steel or ruby replaces in part the verge of the balance. This cylinder is cut away on one side for about one fourth of the circumference, in order to allow the pallets, which are small triangular pieces of steel, to enter the interior. During the swing the pallet rests with little friction on the smooth exterior or interior surface. In entering and in escaping it gives an impulse to the balance. The pallet is not in the

plane of the wheel, but stands on a short stem at right angles to this plane. Hence, the cylinder must be much more extensively cut away at the point where the wheel passes; and on this account the cylinder *E.*, though performing very well, is too frail to be popular in use.—The *chronometer* or *free E.*, of Arnold (Fig. 167), is the most perfect, delicate, and satisfactory in its operations of all the *E.* It is also kept more carefully, at least in marine chronometers, as the gimbal-joint hanging enables it to maintain a constant position relatively to the horizon, and it is carefully guarded from jars. In this *E.* the train is locked by a tooth projecting from a light bar tangent to the *E.*-wheel, which yields by bending and not by turning on a pivot, the fixed extremity being a spring. The free extremity carries another delicate spring parallel to itself and extending a little beyond it. A tooth on the verge passes this slight spring in one direction without sensible resistance. On its return the bar behind the spring prevents its bending, and so is carried along with it, unlocking the train. The train being released, a tooth of the escapement-wheel strikes a pin, or enters a notch, connected with the verge, and gives an impulse to the balance.—The *Duplex E.* of Lepine has two scape-wheels and two pairs of pallets, one for the stop and the other for the impulse.—The *remontoir* gives an impulse to the pendulum by means of a small weight or spring independent of the force of the train. The clock-train winds up the maintaining force at every beat or every few beats.—The *horizontal E.* has a scape-wheel in a plane perpendicular to the axis of the balance; and the teeth are caught in a peculiar way by the edges of a half-cylinder.—The *lever E.* has a lever added to the action of the scape-wheel, to give impulse to the balance.—The *gravity E.* is one which has been made to assume many different forms; a variety devised by Mr. Denison is espe-

Fig. 166. — CYLINDER ESCAPEMENT.

cially intended for astronomical clocks. The making of these delicate pieces of mechanism is among the nicest operations of the horological art. See *CLOCK*, and *WATCH*.

**Escharotics** are substances that destroy the living organic bodies with the production of an "eschar" or "scab." *E.* have been divided into two classes, *mechanical* and *chemical*. Among the

former are actual cauteries, as a heated iron, moxas, etc.; among the latter are all those substances commonly known as caustics.

**Eschen**, a division of the gold and silver pound weight in Hamburg; 544 eschens make one troy pound.

**Escompte** [Fr.], discount; money deducted for interest.

**Escort**, a body of armed men sent for security of convoy, as with a gold freight from the mines to a seaport for shipment.

**Escritoire**, a writing-desk; a chest of drawers with a flap and convenience for writing.

**Escropulo**, the 192d part of the Portuguese and Spanish mark. The scruple is used in Brazil for weighing precious stones, consisting of 3 carats, or about 9½ English grains.

**Escudo**. See *SCRUDO*.

**Esulent**, something that is wholesome and eatable; good as food for man.

by a single laborer. They are generally obtained during the dry summer months, as at other times their adherence to the stems is so firm as often to cause the uprooting of the plants in the attempt to remove them. *E.* may be raised from seed, but cannot be harvested for 12 or 15 years after sowing. The increased demands of the paper-trade have led to forced cropping in some districts, where in consequence there has been a falling off of from 2 to 10 per cent in production. For the processes of the paper manufacturer *E.* is used in the dry state, and without cutting; roots and flowers and stray weeds are first removed, and the material is then boiled with caustic soda, washed, and bleached with chlorine solution. Similar experiments have been made to adapt *E.* for use in the coarser textile fabrics. England is the principal market for *E.*; it is worth on an average \$35 per ton. Several attempts of making paper out of *E.* having failed in the U. States, its importation is limited to a few tons used as filling by certain ships importing manganese ores from Spain. The Department of Agriculture at Washington has been advocating the introduction of *E.*-grass in the American cultivation, but the plant is of a peculiar local nature which cannot be easily transferred to foreign soils and latitudes. *Imp. free.*

**Esprit**. The French word for spirit. This term is commonly applied to alcoholic solutions of the essential oils, and to various odorous and aromatic essences sold by the perfumers and druggists as articles of the toilet. See *ESSENCE*, *SPIRIT*, etc.

**Esquif** [Fr.], a small skiff or ship's boat.

**Esquisse** [Fr.], a sketch; a rough outline drawing.

**Essence**, a volatile oil obtained from a vegetable substance by distillation, or a strong solution of them in alcohol. We confine ourselves here to some general considerations on compound *E.*, or those that undergo some preparation beyond being merely extracted from vegetables by distillation along with water; the latter being considered under the article *OIL (VOLATILE)*. — The concentrated preparations of the pharmacist and the perfumer, termed *E.*, are mostly prepared by digesting the active ingredient or ingredients in rectified spirit of wine, either with or without the addition of a certain portion of water; or they are extemporaneously formed by dissolving a portion of the essential oil of such substances in the spirit. In this way are made the essences of lavender, musk, ginger, etc. When it is desired only to obtain the aromatic and volatile portion of the ingredients, the latter are usually digested in the spirit for a few days, and then submitted to distillation, when the alcohol comes over loaded with aromatic essential oil, or other volatile matter. In this way are prepared most of the fragrant essences of the perfumer and druggist, when simple solution of the essential oils in alcohol is not resorted to. In many cases the active principles of the ingredients are partly volatile and partly fixed, or at least do not readily volatilize at the temperature at which alcohol distils over. This is the case, for instance, with the active portion of ergot and Jamaica ginger. In such cases digestion alone should be adopted. When the principles of organic substances, of which it is desired to obtain a concentrated solution, are resinous or oily, or little soluble in weak spirit (which is mostly the case), the strongest rectified spirit of wine should alone be employed. In the preparation of *E.* without distillation, the method by percolation

Fig. 167. — CHRONOMETER OR FREE ESCAPEMENT.

**Escutcheon**, a shield for a key-hole on a door, etc. — The part of a merchant-vessel's stern where her name is written.

**Espagnolette** [Fr.], a sash-window fastening.

**Espalier** [Fr.], a low lattice-work for training dwarfed fruit-trees on.

**Esparto** or **Spanish Grass**, a species of rush (*Macrorhiza tenacissima*), resembling the ornamental feather-grass of gardens. It is indigenous to the South of Spain and the North of Africa, and is especially abundant in the sterile and rugged parts of Murcia and Valencia, and in Algeria. Its commercial name in Algeria is *Alfa* or *Halfa*. It attains a height of three or four feet. The stems are cylindrical, and clothed with short hair, and grow in clusters of from two to ten feet in circumference; when young they serve as food for cattle, but after a few years' growth acquire great toughness of texture. The leaves vary from six inches to three feet in length, and are gray-green in color. On account of their tenacity of fibre and flexibility they have for centuries been employed for the making of ropes, sandals, baskets, mats, and other articles. Ships' cables of *E.*, being light, have the quality of floating on water, and have long been in use in the Spanish navy. *E.* leaves contain 56 per cent by weight of fibre, or about 10 per cent more than straw, and hence have come largely into requisition as a substitute for linen rags in the manuf. of paper. When required for paper-making the leaves should be gathered before they are quite matured; if, however, they are obtained too young, they furnish a paper having an objectionable semitransparent appearance. The leaves are gathered by hand, and from two to three hundredweight may be collected in a day

or displacement is preferable to that of simple maceration and expression, when the nature of the ingredients and other circumstances render it applicable, as it is not only more economical, but a more concentrated solution may thereby be obtained. At the same time, however, the reader should remember, that this mode of operating requires much greater experience and skill to insure success than the former method. This clumsiness of manipulation is the common cause of the failures which are so frequently met with in the preparation of these articles. The ingredients for the preparation of *E.* must undergo the same operations of bruising, powdering, or slicing, as directed under *TINCTURE*, previous to digestion in the spirit, or other menstruum; and the length of time they should be allowed to infuse, when this method alone is adopted, should not be less than ten days; but this time may be advantageously extended to a fortnight, or even longer. During the whole of this period frequent agitation should be employed, and when the ingredients are so bulky as to absorb the whole of the fluid, the vessel which contains them should be securely fastened by a bung or stopper covered with bladder, and inverted every alternate day. By this means every portion of the ingredients will be equally exposed to the action of the menstruum. In all such cases the method of displacement, or percolation, is preferable. For the *E.* used as perfumes and for flavoring, not only must the spirit be perfectly tasteless and scentless, but it must be also quite devoid of color.—An *E.* whose formula cannot be procured may be readily prepared by applying the general directions given above, or by employing the formula given for the preparation of the *E.* of some similar substance, merely varying the characteristic ingredient. Thus, were it desired to form an *E.* of ambergris or of myrrh, and no formulæ could be found for these preparations, the tyro would consider in what menstruum the active principles of these substances were most soluble. This, he would immediately see by reference to their properties, is rectified spirit of wine. He would next have to decide on the proper strength of his *E.* In this he must be guided, either by the strength of the like preparations of other makers, or by his own judgment of what would be useful, novel, or convenient. Suppose he decided that his *E.* should represent  $\frac{1}{10}$ th of its weight of the solid ingredient. He would then take 2 oz. of ambergris or myrrh, and 20 oz. of rectified spirit, which he would digest together for 10 days or a fortnight in the manner described above. Had the required preparation been an *E.* of senna (for example), he would probably recollect, or might easily ascertain by reference, that the active properties of senna are soluble in both water and weak spirit. Then, to make an *E.* 4 times as strong as the tincture of the pharmacopœia, 7 oz. of senna, and 1 pint of proof spirit, should be employed, with due digestion, as before. See *OIL (VOLATILE)*, *TINCTURE*, *SPIRIT*, etc.—*Imp. duty*, as essential oil, see *OIL (VOLATILE)*; *E.* for perfumes, see *TOILET*.

**Essence d'Orient**, a beautiful glistening matter procured from the blay or bleak, a fish of the genus *cyprinus*. This substance, which is found principally at the base of the scales, is used in the manufacture of artificial pearls. A large quantity of the scales being scraped into water in a tub, are there rubbed between the hands to separate the shining stuff which subsides on repose. The first water being decanted, more is added with agitation till the essence is thoroughly washed from

all impurities, when the whole is thrown upon a sieve; the substance passes through, but the scales are retained. The water being decanted off, the essence is procured in a viscid state, of a bluish-white color, and a pearly aspect. The intestines of the same fish are also covered with this beautiful, glistening matter. Several other fish yield it, but in smaller proportion. When well prepared, it presents exactly the appearance and reflections of the real pearls, or the finest mother-of-pearl; properties which are probably owing to the interposition of some portions of this same substance, between the laminae of these shelly concretions. Its chemical nature has not been investigated; it putrefies readily when kept moist, an accident which may, however, be counteracted by water of ammonia. See *PEARL*.

**Essential Oil.** See *OIL (VOLATILE)*.

**Estada**, the Spanish fathom of six feet.

**Estadal**, a Spanish measure of 100 varas, equal to 274.600 feet.

**Estadio**, a furlong, the eighth part of the Portuguese and Spanish mile, usually subdivided into 125 paces, each of five feet; but in Spain the estadio measures 190 $\frac{1}{2}$  yards, and in Portugal, 281 $\frac{1}{2}$  yards.

**Estado** [Sp.], a statement or account.

**Estafette**, a French courier or express.

**Estame** [Fr.], worsted; woollen yarn.

**Estaminet**, a French alehouse or coffee-house, where smoking is allowed.

**Estancia**, the Spanish name for a grazing-farm or pasture-ground.

**Estate**, the lands or tenements to which a person has a clear title and interest.

**Estimate**, to appraise or value; to judge of by inspection. An estimate is an approximate calculation made of the probable cost or charges of any undertaking, as of a contract for work and labor to be done, a building to be constructed, etc., quantity of materials required for any work, etc.

**Estimator**, an appraiser; one who computes or values.

**Estimo**, in Italian, an impost, tax, or customs duty.

**Establishment of the Port**, a term used by writers on the tides, to denote the interval between the time of high water at any given port and the time of the moon's transit immediately preceding the time of high water, when the moon is in syzygy; that is, at the new or full moon. This interval is influenced by local circumstances, and consequently different at different places. See *TIDE*.

**Estridge**, the fine soft down which lies under the feathers of the ostrich, which was formerly used as a substitute for beaver in hat-making, and of the coarser kind a stuff was fabricated.

**Étagère**, a piece of cabinet furniture; a what-not, sideboard, dumb-waiter, or set of shelves.

**Étair** [Fr.], the finest part of carded wool.

**Étain** [Fr.], tin, pewter, or an alloy of tin and lead.

**Étalon**, the French name for the standard for weights and measures; also a stallion.

**Etching**, a species of engraving, in which the design is formed on the plate by a pointed tool and the action of an acid, or some other fluid, instead of being cut out by the graver. The two countries in which *E.* has been most practised are Holland and France. It has also been successfully practised in Italy, Germany, and England, but not to so great an extent. It has resembled line-engraving in receiving a powerful impulse from celebrated painters; but whereas, with the

exception of Albert Dürer, the painters have seldom been practical line-engravers, they have advanced *E.* not only by advice given to others, but by the work of their own hands. Rembrandt and Claude were practical and very skilful workmen in *E.*, and their works had on this art an influence which still continues. Ostade, Ruysdael, Berghem, Paul Potter, Karl Dujardin, etched as they painted, and so did a greater than any of them, Vandyke. In the earlier part of the present century *E.* was almost a defunct art, except as it was employed by engravers as a help to get faster through their work, of which "engraving" got all the credit, the public being unable to distinguish between etched lines and lines cut with the graver. During the last fifteen or twenty years, however, there has been a great revival, which has extended all over Europe and the U. States, though France has had by far the largest and most important share in it. It was hoped, at the beginning of this revival, that it would lead to the production of many fine original works; but the commercial law of demand and supply has unfortunately made modern *E.* almost entirely the slave of painting. Nearly all the clever etchers are occupied in translating pictures, which many of them do with remarkable ability, even to the very touch and texture of the painter. The comparative rapidity of the process, and the ease with which it imitates the manner of painters, have caused *E.* to be now very generally preferred by publishers for the translation of all pictures except those belonging to a severe and classical style of art, for which the graver is, and will always remain, better adapted than the *E.*-needle. Yet, notwithstanding the present commercial predominance of *E.* from pictures, there are still in Europe, and we have at the present day in Boston, New York, and Philadelphia, some artists and eminent amateurs who cultivate original *E.* with success, and produce works of very various interest and power.

To prepare a plate for *E.*, it is first covered with *E.*-ground, a composition which resists acid. The qualities of a ground are to be so adhesive that it will not quit the copper when a small quantity is left isolated between lines, yet not so adhesive that the *E.* point cannot easily and entirely remove it; at the same time a good ground will be hard enough to bear the hand upon it, or a sheet of paper, yet not so hard as to be brittle. The best is that of Abraham Bosse, which is composed as follows: Melt 2 oz. of white wax; then add 1 oz. of gum-mastic in powder, a little at a time, stirring till the wax and the mastic are well mingled; then add, in the same manner, 1 oz. of bitumen in powder. There are three different ways of applying an *E.*-ground to a plate. The old-fashioned way was to wrap a ball of the ground in silk, heat the plate, and then rub the ball upon the surface, enough of the ground to cover the plate melting through the silk. To equalize the ground a dabber was used, which was made of cotton-wool under horse-hair, the whole enclosed in silk. This method is still used by many artists, from tradition and habit, but it is far inferior in perfection and convenience to that which we will now describe. When the *E.*-ground is melted, add to it half its volume of essential oil of lavender, mix well, and allow the mixture to cool. You have now a paste which can be spread upon a cold plate with a roller; these rollers are covered with leather and made (very carefully) for the purpose. You first spread a little paste on a sheet of glass (if too thick, add more oil of lavender and mix with a palette-knife), and roll it till the roller is quite equally charged all over, when the paste is easily transferred to the copper, which is afterwards gently heated to expel the oil of lavender. In both these methods of grounding a plate the work is not completed until the ground has been smoked, which is effected as follows: The plate is held by a hand-vice if a small one, or, if large, is fixed at some height, with the covered side downwards. A smoking torch, composed of many thin beeswax dips twisted together, is then lighted and passed repeatedly under the plate in every direction, till the ground has incorporated enough lamp-black to blacken it. The third way of covering a plate for *E.* is to apply the ground in solution as collodion is applied by photographers. The ground may be dissolved in chloroform or in oil of lavender. The plate being grounded, its back and edges are protected from the acid by Japan varnish, which soon dries, and then the

drawing is traced upon it. The best way of tracing a drawing is to use sheet gelatine, which is employed as follows: The gelatine is laid upon the drawing, which its transparency allows you to see perfectly, and you trace the lines by scratching the smooth surface with a sharp point. You then fill these scratches with fine black-lead in powder, rubbing it in with the finger, turn the tracing with its face to the plate, and rub the back of it with a burnisher. The black-lead from the scratches adheres to the *E.*-ground and shows upon it as pale gray, much more visible than anything else you can use for tracing. Then comes the work of the *E.*-needle, which is merely a piece of steel sharpened more or less. Turner used a prong of an old steel fork, which did as well as anything, but better *E.*-needles are sold by artists' color-makers. The needle removes the acid and lays the copper bare. Some artists sharpen their needles so as to present a cutting edge which, when used sideways, scrapes away a broad line; and many etchers use needles of various degrees of sharpness to get thicker or thinner lines. It may be well to observe, in connection with this part of the subject, that whilst thick lines agree perfectly well with the nature of woodcut, they are very apt to give an unpleasant heaviness to plate engraving of all kinds, whilst thin lines have generally a clear and agreeable appearance in plate engraving. Nevertheless, lines of moderate thickness are used effectively in *E.* when covered with finer shading, and very thick lines indeed were employed with good results by Turner when he intended to cover them with mezzotint, and to print in brown ink, because their thickness was essential to prevent them from being overwhelmed by the mezzotint, and the brown ink made them print less heavily than black. Etchers differ in opinion as to whether the needle ought to scratch the copper or simply to glide upon its surface. A gilding needle is much more free, and therefore communicates a greater appearance of freedom to the *E.*, but it has the inconvenience that the *E.*-ground may not always be entirely removed, and then the lines may be defective from insufficient biting. A scratching needle, on the other hand, is free from this serious inconvenience, but it must not scratch irregularly so as to engrave lines of various depth. The biting in former times was generally done with a mixture of nitrous acid and water, in equal proportions; but in the present day a Dutch mordant is a good deal used, which is composed as follows: Hydrochloric acid, 100 grammes; chlorate of potash, 20 grammes; water, 880 grammes. To make it, heat the water, add the chlorate of potash, wait till it is entirely dissolved, then add the acid. The nitrous mordant acts rapidly, and causes ebullition; the Dutch mordant acts slowly, and causes no ebullition. The nitrous mordant widens the lines; the Dutch mordant bites in depth, and does not widen the lines to any perceptible degree. The time required for both depends upon temperature. A mordant bites slowly when cold, and more and more rapidly when heated. To obviate irregularity caused by difference of temperature, it is a good plan to heat the Dutch mordant artificially to 95° F. by lamps under the bath (for which a photographer's porcelain tray is most convenient), and keep it steadily to that temperature; the results may then be counted upon; but whatever the temperature fixed upon, the results will be regular if it is regular. To get different degrees of biting on the same plate the lines which are to be pale are "stopped out" by being painted over with Japan varnish or with *E.*-ground dissolved in oil of lavender, the darkest lines being reserved to the last, as they have to bite longest. When the acid has done its work properly the lines are bitten in such various degrees of depth that they will print with the degree of blackness required; but if some parts of the subject require to be made paler, they can be lowered by rubbing them with charcoal and olive oil, and if they have to be made deeper they can be rebitten, or covered with added shading. Rebiting is done with the roller above mentioned, which is now charged very lightly with paste and rolled over the copper with no pressure but its own weight, so as to cover the smooth surface, but not fill up any of the lines. The oil of lavender is then expelled as before by gently heating the plate, but it is not smoked. The lines which require rebiting may now be rebitten, and the others preserved against the action of the acid by stopping out. These are a few of the most essential technical points in *E.*, but there are many matters of detail, for which the reader is referred to the special works on the subject.

***E.* on glass.** The ground is laid on, and the design "scratched in" in the usual way, when liquid hydrofluoric acid is applied, or the glass is exposed to the action of hydrofluoric acid gas. The former renders the surface of the *E.* transparent, the latter opaque. A simple modification of the process is to wet the design with sulphuric acid, and then to sprinkle on some finely pulverized fluor spar (fluoride of calcium), by which means hydrofluoric acid is set free and attacks the glass. This method may be very easily applied to the graduation of glass vessels, thermometer tubes, etc.

***Electro E.*** This mode of *E.* is based upon the destructive action of certain "anions" during "electrolysis." If two plates of copper be connected with the opposite ends of a voltaic battery, and placed in a vessel containing very dilute sulphuric acid, the plate connected with the copper of the battery will be attacked by the anion oxygen which is released

during the decomposition of the acid. This destructive action can be localized at pleasure by covering certain parts of the plate with a protecting stratum of varnish, ordinary *E.*-ground, for instance. In the practice of electro-*E.*, the drawing is "scratched in" in the usual way through an ordinary ground; a stout wire is then soldered to the plate, and this, as well as the back of the plate, is coated with sealing-wax varnish. Thus prepared, the plate is placed in a suitable "decomposition cell" opposite a plate of somewhat similar size, and the two are connected respectively with the copper and zinc of a Daniell's cell, or the silver and zinc of a Snec's cell. After about ten minutes the plate is removed, washed, and dried; and when the "fine work" has been stopped out with Brunswick black, it is returned for another space of ten minutes. By alternately exposing the plate to the action of the decomposing fluid, and "stopping out" parts of the work, the required gradation in tints is obtained. The exact duration of the various exposures, as well as their number, must of course be regulated by circumstances.

**Ether**, a name given to numerous chemical compounds, generally derived from alcohols by the action of acids. The most important body of this series is the common *E.* or *ethyl E.*, commonly called *sulphuric E.*, a colorless, transparent, highly volatile, fragrant, inflammable liquid, obtained by distilling a mixture of sulphuric acid and alcohol. It has a penetrating and agreeable smell, and a burning, sweetish taste; its evaporation produces the sensation of extreme cold; when prevented, a sensation of heat is experienced. Its sp. gr. varies between .712 and .724. If it contains water it begins to crystallize in brilliant white plates when cooled to  $-24^{\circ}$  F., and become a white crystalline mass at  $-46^{\circ}$  or  $-47^{\circ}$  F.; but if absolutely pure, *E.* cannot be solidified by any degree of cold that can be produced, it remaining fluid when placed in contact with solid carbonic acid, at a temperature of about  $-148^{\circ}$  F. Boils at  $96^{\circ}$  or  $97^{\circ}$  F.; is very combustible; is soluble in about 10 parts of distilled water, and mixes with alcohol in all proportions. It abstracts corrosive sublimate, tetrachloride of gold, sesquichloride of iron, and many of the alkaloids, from their watery solutions, and is hence invaluable in analysis and pharmacy. It readily dissolves the volatile and fixed oils, and most fatty matters, as well as sulphur and phosphorus in small quantities. By exposure to light and air it absorbs oxygen, and water and acetic acid are gradually formed. It is decomposed by exposure to a high temperature. The greatest degree of cold yet produced ( $-166^{\circ}$  F.) has resulted from the admixture of *E.* with solid carbonic acid. *E.* is powerfully stimulant, narcotic, and antispasmodic, and externally refrigerant, if allowed to evaporate, or stimulant and counter-irritant if its evaporation is prevented, and is used in various diseases. Applied to the forehead by means of the fingers or a strip of linen, it generally relieves simple cases of nervous headache. In *pharmacy* it is largely employed in the preparations of tinctures, alkaloids, spirits, etc.; and in *chemistry* it is invaluable in organic analyses. Its principal commercial application is as a solvent for pyroxyline, in the manufacture of collodion. It is also employed as a solvent of resins, india-rubber, etc., in the preparation of varnishes, and for several other useful purposes. Shortly before the discovery of chloroform, it was found that when the vapor of *E.* was inhaled it gradually produced insensibility to pain. It was therefore employed as an anæsthetic in surgical operations. Having been found less efficient than chloroform, and more troublesome to administer, its use for this purpose has been abandoned.

*E.* may be recognized by its volatility, odor, taste, sparing solubility in water, admixture with alcohol in all proportions, great inflammability (burning with a yellowish-white flame), and its power of dissolving fats and resins. Its further identi-

fication can only be effected by ultimate analysis. The *E.* of commerce generally contains alcohol, water, or acetic acid, and sometimes all of them. Its usual sp. gr. fluctuates between .733 and .755. Exposed to the air, it volatilizes entirely. It turns litmus paper red; sometimes very slightly, and occasionally even not at all.  $\frac{1}{2}$  fluid ounce mixes completely with  $\frac{1}{2}$  pint of water. Pure *E.* should, however, be neutral to test-paper, although seldom so. When shaken in a minim measure with half its volume of concentrated solution of chloride of calcium, its volume should not lessen. 10 fluid ounces of water should only dissolve 1 fluid ounce of *E.*, and remain transparent. — *E.* rapidly evaporates at common temperatures when kept in corked bottles, and even in bottles secured with ground-glass stoppers and tightly tied over with bladder and leather; it also becomes sour by age. To prevent this waste, the stoppers should fit accurately, and the bottles should be placed in as cool a situation as possible. Bottles furnished with ground-glass caps, as well as stoppers, are frequently employed. — The vapor of *E.* is very inflammable, and when mixed with atmospheric air it forms a violently explosive mixture. The density of this vapor is 2.586, that of air being 1; hence it rapidly sinks and frequently accumulates in the lower parts of buildings, especially cellars which are badly ventilated, in the same way as water does. The only remedy is thorough ventilation. Many serious accidents have arisen from this cause, for no sooner is a light carried into an apartment where such vapor is present than an explosion takes place. — *Imp. duty*, \$1 per lb.

**Etiquette**, ceremony. — In France, a label or ticket affixed to a package.

**Etna**, a table cooking-utensil, heated by a spirit-lamp.

**Etoupe** [Fr.], tow; lint; the coarsest part of flax or hemp; oakum.

**Etui**, a case for holding small articles, as a lady's work-box and case for articles of needle-work.

**Eudiometer**, an instrument for ascertaining the purity or salubrity of air, or rather for determining the quantity of oxygen in any given bulk of elastic fluid.

**Euphorbia**, a concrete gum-resin obtained from several East Indian species of *Euphorbia*. It is inodorous, and, when first chewed, has little taste; but it soon gives a very acrid, burning impression to the tongue, palate, and throat, which is very permanent, and almost insupportable. At one time it was used in medicine, both externally and internally; but in consequence of its violent action its use is now discontinued. Its chief employment is for veterinary purposes. It is imported in serons, containing from 100 to 150 lbs. It is in small, hollow, forked pieces, often mixed with seeds and other impurities.

**Eureka and Palisade R.R. Co.** runs from Palisade, Nev., to Eureka, Nev., 90 m., with a branch line from the latter place to Ruby Hill, a distance of 7 m. The Co., whose offices are in Eureka, was chartered in 1874, and the road opened in 1876. The financial standing of this Co. is unknown.

**Evansville and Terre Haute R.R.** runs from Evansville to Terre Haute, Ind., 109 m., with an extension from Terre Haute to Rockville, 21.88 m. This Co., whose offices are in Evansville, was formed by the consolidation of the Crawfordsville and Illinois R.R., and the Terre Haute and Vincennes, and took its present title in 1877. *Financial Statement*: Cap. stock, common, \$1,020,416.27; preferred 7%, \$100,000; funded debt, \$1,017,000, as follows, — 1st mortgage (Evansville and Illinois R.R., 51 m.), issued 1852, payable 1887, \$281,000, interest 7% (Jan. and July); 1st mortgage sinking fund (Evansville and Crawfordsville R.R., 109 m.), issued 1854, payable 1887, \$611,000, interest 7% (May and Nov.); 1st mortgage (Rockville Extension), issued 1860, \$125,000, interest 7% (Feb. and Aug.).

**Evansville, Terre Haute, and Chicago R.R.** runs from Terre Haute, Ind., to Danville, Ill., a distance of 55.28 m. This Co., whose offices are

in Terre Haute, was chartered in 1869, and the road opened in 1871. It uses the Rockville Extension of the Evansville and Crawfordsville R.R. from the Junction to Terre Haute, a distance of 6 m., for which it pays a rent of \$5,000 per annum. The Co. also rents on lease the Indiana Black Coal R.R. *Financial statement, 1879*: Cap. stock, \$458,661; funded debt, \$1,100,000, as follows:—1st mortgage on road in Ind., issued 1870, payable 1900, \$775,000, interest 7% (May and Nov.); 1st mortgage on road in Ill., and 2d mortgage on road in Ind., issued in 1873, payable 1903, \$325,000, interest 7% (Jan. and July).

**Evaporameter**, a hygroscope or atmometer, an instrument for ascertaining the evaporation of fluids.

**Evaporation**, the conversion of a fluid into vapor by means of heat, diminished atmospheric pressure, or exposure to a dry atmosphere.

*E* is had recourse to: 1. For the vapor as a source of heat or power, as in the case of steam-boilers, etc.; 2. To separate volatile fluids from impurities or other bodies, which are either fixed or less volatile; 3. To recover solid bodies from their solutions, as in the preparation of extracts, chemical salts, etc.; 4. To concentrate or strengthen a solution by the expulsion of some of the fluid matter that forms the menstruum; 5. To purify liquids by the dissipation of the volatile matters which may contaminate them. It is found that, under ordinary circumstances, *E*, is confined to the surface of the heated liquid, and is therefore slower or quicker, in proportion to the extension of that surface. Hence has arisen the adoption of wide, shallow vessels for containing fluids during their exposure to heat for this purpose. *E* proceeds most rapidly when a current of air (especially hot and dry air) is made to pass over the surface of the fluid; as in this case the vapor is prevented resting upon the surface, and impelling the process by its pressure. For a similar reason, liquids evaporate more rapidly in vessels partially covered than in open ones. In the former case the cool incumbent air condenses and throws back a portion of the vapor, which thereupon, besides its cooling action, offers mechanical resistance to the diffusion of the vaporous particles as they arrive at the surface of the liquid. In the latter case these obstacles are avoided, and the impetus of the vapor pouring forth from a contracted orifice, or pipe, not only readily overcomes the pressure of the atmosphere, but offers less surface for its cooling action, until it has passed much beyond the points at which it can exert any influence on the fluid from which it has escaped. In this way the chemical action of the atmosphere on the liquid operated on is also considerably lessened. On the small scale, shallow capsules of glass, wood, ware, porcelain, or metal, are commonly employed as evaporating vessels, and these are exposed to heat by placing them over a lamp, or naked fire, or in a water bath, or sand-bath, according to the temperature at which it is proper to conduct the process. On the large scale, high-pressure steam is usually employed as the source of heat. The term "spontaneous *E*," is applied to the dissipation of a fluid by mere exposure in open vessels, at the common temperature of the atmosphere, and without the application of artificial heat. The celerity of this species of *E* wholly depends on the degree of humidity of the surrounding air, and differs from the former, in which the rate of *E* is proportionate to the degree of heat at which the process is conducted, and the amount of pressure upon the surface of the liquid. *E* *in vacuo* (as it is called) is conducted under the receiver of an air-pump, or in an attenuated atmosphere, produced by filling a vessel with steam, by which means the air is expelled, when all communication with the external atmosphere is cut off, and the vapor condensed by the application of cold. Fluids are also evaporated in air-tight receivers over sulphuric acid, by which they are continually exposed to the action of a very dry atmosphere. When such a receiver is connected with an air-pump in action, *E* proceeds with increased rapidity, and intense cold is produced. If the bottom of a pan, and the portion of the sides immersed in a hot fluid medium (solution of chloride of calcium, for example), be corrugated, so as to contain a double expanse of metallic surface, that pan will evaporate exactly double the quantity of water, in a given time, which a like pan, with smooth bottom and sides, will do, immersed equally deep in the same bath. If the corrugation contain three times the quantity of metallic surface, the *E* will be threefold in the above circumstances. But if the pan, with the same corrugated bottom and sides, be set over a fire, or in an oblique flue, so that the current of flame may sweep along the corrugations, it will evaporate no more water from its interior than a smooth pan of like shape and dimensions placed alongside it in the same flue, or over the same fire. In the laboratory, steam heat is now almost exclusively employed. Copper or tinned, glazed, or silvered pans, boilers and stills are surrounded by a "jacket" of cast iron, and high-pressure

steam admitted between the two. By due management of the supply-cock, a range of temperature may be thus obtained extending from about 90° to 325° F. It is found that, under ordinary circumstances, 10 sq. feet of heated surface will evaporate fully 1 lb. of water per minute, and that a thin copper tube exposing 10 feet surface will condense about 3 lbs. of steam per minute, with a difference of temperature of about 90° F. This is equal to 30° F. per lb.; and, consequently, the heat of the steam employed to produce the *E*, should be 212° + 30° = 242° F.

**Evaporator**, an apparatus for condensing vegetable juices, of which there are many varieties, generally consisting of a furnace and pan.

**Even Keel**, a vessel which is loaded so as to draw the same water abaft as forward.

**Eventail**, the French word for a fan.

**Evergreens**, plants which retain their verdure throughout the year, such as pines, laurels, hollies, etc.

**Ever-pointed Pencil**, a sliding screw pencil-case, by which the lead is brought forward as fast as wear renders it necessary.

**Evidence**, oral or written testimony given by a witness.

**Evolutions**, the movements of a vessel or fleet.

**Ewe-Cheese**, cheese made from the milk of sheep.

**Ewer**, a water-pitcher with a wide spout.

**Ex**, a Latin preposition, which denotes out of, or from.

**Examination**, a careful search or inspection; a judicial trial, inquiry, or proceeding.

**Examiner**, an inspector or investigator; one appointed to test or scrutinize accounts, or to assay by experiments.

**Excavation**, a digging or hollowing out.

**Excavator**, a machine for excavating; also, one who cuts or digs out earth.

**Exchange**, a term that is used in reference to those transactions by which the debts of persons residing at a distance from their creditors are liquidated without the transmission of money; being employed by merchants both to designate the bills or negotiable instruments by which transactions of this kind are conducted, and the varying price or course of such instruments in the market. The nature, constitution, and negotiation of **BILLS OF EXCHANGE** having been already explained under that head, the present article will be devoted to an explanation of the principles by which *E*. transactions are regulated.—Among cities or countries having any considerable intercourse together, the debts mutually due by each other approach, for the most part, near to an equality. There are at all times, for example, a considerable number of persons in New York indebted to London; but, speaking generally, there are about an equal number of persons in New York to whom London is indebted. And hence, when A of New York has a payment to make to B of London, he does not remit an equivalent sum of money to the latter, but he goes into the market and buys a *bill* upon London; that is, he buys an order from C of New York addressed to his debtor D of London, requesting him to pay the amount to A or his order. A, having indorsed this bill or order, sends it to B, who receives payment from his neighbor D. The convenience of all parties is consulted by a transaction of this sort. The debts due by A to B, and by D to C, are extinguished without the intervention of any money. A of New York pays C of ditto, and D of London pays B of ditto. The debtor in one place is substituted for the debtor in another; and one or two postages form the whole expense. All risk of loss is obviated—A bill of *E*., therefore, may be defined to be an order

addressed to a person residing abroad, directing him to pay a determinate sum of foreign money to the person in whose favor it is drawn, or to his order. The amount of foreign money, therefore, to be paid is fixed by the bill; but the amount of American money (or money of the country in which the drawer resides), to be given for the purchase of the bill, is by no means fixed, but is continually varying. The various elements entering into the valuation of foreign bills, or, in other words, the rate of foreign *E.*, may be conveniently embraced under the following heads: (1) par of *E.*; (2) supply and demand of bills; (3) rate of interest; (4) cost of specie remittance, to which may be added, what is always implied, (5) correct judgment of the force and duration of the cause or causes affecting the rate of *E.*, or its opposite, panic. — 1. *Par of E.* Without some common medium of value in commercial countries bills of *E.* could not be drawn between one and another. The "cash" of China has played no more part in the foreign *E.* than the cowries of Africa; but since a mint has been established in Japan, from which gold pieces are issued under public regulation as to weight and fineness, there may be no difficulty in ascertaining the monetary equivalency at Yokohama of any debt due by Japan to the U. States, or *vice versa*. The nations have thus found a medium of *E.* in bullion, in gold or silver, or in both. In countries of the double standard, it has been usual to modify the law by liberty of contract for payment in one of the metals, without which liberty, indeed, it would be as well to have only one standard, since it is certain that the debtor will always choose to pay in the metal that has become relatively cheaper. In countries where silver is the sole standard, the par of silver to gold may be 15 to 1, or 16 to 1, as law or custom may have established; but in foreign *E.* the par of silver to gold cannot be fixed at any absolute point by the law of any one country, and in the case of a depreciation, say of silver, even though temporary, by which the market price of silver to gold became 17 to 1, a proportionate addition would be made to the figures of the mint or former customary par, and this new sum become practically the par of *E.* between the gold currency of the U. States and the silver dollars of Mexico or rupees of India. Thus, having gold and silver to deal with, it is always possible, whatever may be the variety and names of the coins of different countries, to estimate the equivalents of the one to the other. This is a matter simply of weight and assay; and the ratio thus found is the par of *E.* between one country and another. — Mr. McCulloch seems to have thought that the par of *E.* should properly include, not only equivalent weight and purity of the precious metals, but their relative cheapness or dearness in given places. "Thus," he says, "if, because of the expense of carriage, the value of bullion in Great Britain be 5 per cent greater than in San Francisco, 100 ounces of pure gold in the latter would not be worth 100 ounces of pure gold in London, but 5 per cent less; and the *E.* would be at true par when bills for 105 ounces standard bullion, payable in San Francisco, sold in London for 100 ounces." Since this has not been the practice in determining the par of exchange, — the 25.30 of Paris, and the old 109 of New York, etc., with London having been based more or less exactly on equal weights of pure gold for pure gold, — a question is suggested which the following considerations may help to resolve. The 5 per cent claimed from San Francisco is for a relative

dearness of gold in London, which can only be overcome by carrying the gold from the one place to the other; but it would be illogical to charge in a bill of *E.* for a transport of specie which it is the express object and effect of the bill to supersede. The merchant in London would be entitled to sell a bill on San Francisco for a sum equal to 100 ounces of gold, and to include the cost of *E.*, if any; or his debtor in San Francisco might buy a bill on London for a sum sterling equal to 100 ounces of gold; and if the course of *E.* were such that this bill cost him only 99 ounces, the merchant in London would yet have no reason to complain. If neither of these modes of settlement were available, the debtor in San Francisco would have to send 100 ounces of gold to London, in which case there would be no rate of exchange in question.

But, apart from the less value of bullion in some countries than in others, owing to nearness to the mines or other causes, there is a cheapness of the metallic money, as well as the general currency of a country, which operates directly on the rate of *E.*, and requires in one form or other the recognition of a different par from that established under other conditions. The standard may be tampered with; the alloy may be increased; the weight of the coins may be diminished and diminished till, like the Turkish piastre, they become scarce a shadow of themselves. It is obvious that innovations of this kind compel a rectification of the estimated par of *E.* In other cases coins are legitimately changed; and these variations, in so far as they supersede or modify coins which entered into the par estimate, are bound to have a new rating. A country which allows its coinage to be much worn, defaced, and generally light in weight is in the same position as one which has deliberately lowered its standard of value; for though its light coins, when sent abroad, which they are not apt to be, count for no more than they weigh, there is the other and more serious effect that they may have been already well weighed at home, and have so raised the prices of the goods of the country as to place all dealings in them under a delusion as to their real value. One may well believe, however, that this is a form of monetary evil which has now passed away. There will always be some more or less worn and light coins in a metallic circulation, and as long as these are limited in number, and circulate in the country of their coinage at the mint price, they do little or no harm. There is a much more convenient process by which to cheapen the money of a country than any form of debasing the coinage, namely, to dispense wholly or almost wholly with metallic money in favor of an inconvertible paper currency. — When a country is impelled to issue paper money not payable on demand in gold or silver, its monetary value slips away from all fixed reckoning. The first effects are so agreeable as naturally to lead to a larger and a still larger issue, and the agreeable effects are prolonged until the real situation begins to be disclosed, and, finally, derangement has spread so widely on all sides that extrication becomes a task of the gravest difficulty. The effects even on the foreign *E.* are for a time somewhat illusive. There being no more need for gold and silver, nearly the whole stock of bullion passes out, and like a new-found capital gives ample power of purchase abroad. The importer, finding that there are increasing prices for every commodity in the paper money, goes into his business with new heart and will. The premium, which has

early begun to be established on foreign bills, soon becomes so large that the exporter imagines that he can make a fair profit out of the premium on his foreign bill alone, though there may not be a margin of a fraction of one per cent of profit in the actual trade. Supposing such a result possible to the exporter, it is clear that he makes his profit entirely out of his neighbor the importer, who has to buy his bill, and consequently to pay the premium. Both cannot be right in their views, and in point of fact both are wrong until they begin to realize that the inconvertible paper dollar, rouble, or florin is not so valuable and has not the same purchasing power as the metallic money, or as the paper notes maintained in a constant practical convertibility. This fact is demonstrated within the country itself by the more or less gradual and uniform, but inevitable, rise of prices of all commodities, and of bullion among others, in this new currency. It is discovered very early in the foreign *E.*, not only since there is likely to be an excess of imports over exports when a country is in the act of denuding itself of specie, but because the foreigner has to be careful to get the value of his goods or produce as it is known to him in his own money; and any important change in the money of a country, therefore, obtains a sharp valuation abroad. Both at home and abroad it is soon discovered that the par of *E.*, as formerly established, has passed away, and that a new par has come into operation under the pure force of the natural relations of the case. The importer finds no advantage from the advancing prices of what he imports in the domestic markets, since he has to pay more of the domestic money for the foreign bill of exchange by which he discharges the debt for his imports; and the exporter finds no advantage in the premium on his foreign bill which he sells to the importer, since it only replaces what he has already paid in the increased cost of his commodities and other outlays. This action of *E.* is now so familiar as to require no illustration. — As long as a change in the par of the money of two countries is not recognized or clearly understood, there may be much miscalculation and irregular profit and loss among the merchants on both sides. On the other hand, as soon as noted and brought under generally acknowledged estimate, it does not interfere, *per se*, with the movement of produce or the fair profits of those engaged in foreign trade. But how is the depreciation of an inconvertible paper currency to be measured? As a convertible paper currency only maintains its par with gold by being always payable on demand in the gold it promises to pay, so an inconvertible paper currency falls just so much below the par of gold as the difference between the amount of gold it professes to be and the amount of gold it exchanges for in its own market. The price of bullion in an inconvertible paper currency rises like that of other commodities, — not, indeed, in its general market value, but in its market price within the sphere of the currency, and the amount of this rise marks what may be called either a discount on the paper money, or a premium on the gold, and this discount or premium becomes a measure of the depreciation of the currency. It is by no means a satisfactory standard, for it may vary from day to day, and in this respect be as unlike as possible to a par of *E.* between the gold and silver moneys alike of small and great states, which may hold good without variation for any number of years. There may also be restrictions on the sale of bullion, prohibition of the sale of bullion, and speculative combi-

nations of paper-holders and gold-holders to "corner" each other, and the fluctuations may be not only constant but sometimes extreme. But, with all its disadvantages, the relation of gold to the paper money, as it happens to be revealed in the markets, is the only measure of the depreciation to be had, and the premium on gold has consequently to be reckoned as a necessary component part of the rate of *E.* with other countries. — The effect of issues of inconvertible paper money, or the suspension of cash payment of paper currency already in circulation on the par of *E.*, is the same as that of a change of the standard of value, a debasement of the coinage, or, where in one of the two countries the money is gold, and in the other silver, a depreciation of one metal as compared with the other. When two countries par their gold coins, the object is to arrive at a common term by which value for value will be paid, in equivalent weight and purity of metal, out of the money of each other. When one of them displaces its gold coins by inconvertible paper money, the same object has to be attained, and this is reached, though not so fixedly as in the par of metallic coins, by the premium which gold commands over the paper money in the sphere of its currency. The former par, in such cases, may be adhered to as a landmark, and this gold premium may be treated as nominal premium on one side and nominal discount on the other; but it is substantially of the nature of par of *E.*, and becomes a necessary integer of the rate of *E.* In the case of countries of one of which gold, and of the other silver, is the standard money, the nominal par is subject to variation from changes in the relative market value of the two metals. If, for example, the relation on which the par proceeded was 15 ounces of silver equal to 1 ounce of gold, and the depreciation of silver becomes such that 17 ounces will buy only 1 ounce of gold, the par of *E.* between the two countries will follow the course of that depreciation. — The course of the *E.* of India has been much affected of late years by the depreciation of silver, and so, also, those of all silver-paying countries. The drawer of a bill sterling on London in Calcutta or Bombay is literally selling gold for silver, and, whatever the more ordinary par may have been, is bound to take into account the market value of silver. In 1876, owing to the large quantity of demonetized German silver thrown upon the market, less directly to a pre-existing cause, namely, the large extent to which silver had been cast out even of the fractional currency of countries largely committed to inconvertible paper, and also to exaggerated reports of abundant increase of production in the American mines, silver fell to 47*d.* an ounce, about the lowest point reached in its relation to gold, and a great reduction from what had long been its par value of 5*s.* 2*d.* an ounce. The consequence was that the Indian rate of *E.* declined to 1*s.* 6½*d.* per rupee in six months' sight bills on London, or, in other words, that the rupee, having an accustomed par value of near 2*s.*, was worth only 1*s.* 6½*d.* sterling, *minus* say seven months' interest accruing between the date and the maturity of the bill. It is difficult, or rather impossible, as foreign bills are negotiated, to distinguish the respective force of the various causes operating on the rate of *E.* In the case of India, nearly all the constituents of *E.* are adverse to the value of the rupee, save that of rate of interest, which is higher in Calcutta or Bombay than in London. The Indian drawer of a six months' bill on London would lose more by holding the bill till its matu-

city than the buyer of the bill who remits it to London for acceptance and discount; and some middle term must be struck between them, according as the rates of interest in India and England vary. But, on the other hand, India is a country where the imports always exceed the exports, where foreign capital in many forms has been largely invested and has to render its annual tribute, and where the financial relations of the government of India and the government of England are such that the latter has to draw periodically a considerable amount of bills on the Indian treasuries; so that, whatever the par of gold and silver might be, the supply of bills on London would always be less than the demand, or, in other words, the Indian creditors have some advantage over the Indian debtors of London in the rate of *E*. Were gold the money of India, the range of the premium thus established on the bill on London would be limited by the cost of remitting gold; but silver being the money of India, the action of the premium itself, or rather of the relative indebtedness of which it is the result, is to extend the range of the specie limit by lessening the demand for silver abroad. The rupee being less valuable than it formerly was does less work in the Indian circulation, and is all the more needed at home; to export it in payment of the adverse balance of trade, would be to send it where it is less valuable still. It may thus be concluded that the depreciation of silver has been much the most potent and constant element in the adverse current of Indian *E*. The price of silver having since 1876 risen to 53½*d.*, the rate of six months' bills in London has risen to 1*s.* 8¾*d.* The rate of Indian *E*. rises in the export seasons, when the supply of foreign bills is increased; and it rises with the price of silver at all seasons. — In the silver *E*. between Hamburg and London the same rule prevailed. In Hamburg silver was money, but in England and other countries, which have a gold standard, it is only merchandise; and a rise or fall in the price of silver affected the value of a bill on Hamburg, or a bill drawn on Hamburg in English sovereigns. Where a double standard exists, as in the U. States and France, bills between one of these countries and another are drawn in the standard which is common to both. Thus, in the direct *E*. between New York and London, the bills are usually or almost wholly gold bills. — 2. *Supply and Demand of Bills.* Were there a common international money, the supply and demand of bills would be the chief determining cause of a rise or fall in the rate of *E*. Hence, in distinction from the nominal par, the relation of supply and demand of bills has been called "real *E*." Mr. Goschen speaks of it as "the primary element in the value of bills," which, from so practical an authority, may be regarded as indicating that, notwithstanding all the varieties of money, this continues to hold the chief place in the negotiation of bills of *E*., or that, the nominal par being once determined, or a common principle formed for its rectification when the money of a country has depreciated, it ceases to require the calculation which must always be given to the supply and demand of bills in the market. As the sum of the bills offered, and the sum ready to be bought, never express the whole of the claims upon, or the whole of the debts due to a country, but only such claims as have been drawn for, and debts the time of payment of which has come, or is nearly approaching, there is always more or less change of the relation of supply and demand, as well as opportunity of judgment as to the probable course of the market,

and means of applying correctives if the balance be swaying too much on the one side or the other. If the price of foreign bills be depressed for want of buyers, drawers may hold back a little; on the other hand, if the demand has raised the price of bills, all who have sums to draw for will be induced to take advantage of the market, and so increase the supply. The buyers are moved in the same way, quickening or delaying their purchase within the limits of their period of remittance, according to their judgment of the probable course of the *E*. But the buyer cannot delay beyond the day when his remittance is due in the foreign country, nor the drawer beyond the ultimate date of drawing, or his own need of realizing the value of his bill; so that, amidst this oscillation, it is always the peremptory business to be done that determines the effect of supply and demand on the rate of *E*. The debtors of a foreign country, finding the supply of bills on that country less than the demand, will be ready to give an addition of price for them, in proportion to the scarcity, within the cost or up to the cost of remitting specie; and the creditors or drawers on a foreign country will submit in the other extremity to discount on their bills within the cost of sending them to their correspondent or banker's correspondent abroad, with orders to take payment and remit the proceeds in specie. When the course of *E*., as thus pursued from week to week, reveals that the claims immediate and maturing upon any country are greater than the debts due to it, and cannot be discharged through the mechanism of direct and indirect bills of *E*., its balance of debt can only be paid by remittances of bullion, or an increased export of goods and produce, or other exportable value. It is unnecessary to dwell further on the law of supply and demand of bills, which differs little from that of other commodities, beyond remarking that an inadequate idea would be formed of the efficacy of bills of *E*. in liquidating international debts without taking into account an immense banking organization, aided by bill-brokers and dealers in foreign *E*., who have all the main currents of indebtedness under their eyes, and know with the precision of practice how the debts of one centre can be met by its claims upon others, and a stupendous mass of conflicting operations, ordinary and extraordinary, be most economically effected. Fifty or a hundred millions sterling, as in the case of the French indemnity to Germany, can be transferred from Paris to Berlin at a time without material disturbance of the more ordinary business of *E*. When England is lending ten millions to India, fifteen millions to the Australian colonies, or so many millions to Russia, Turkey, or the River Plate republics, — or making several of such loans at nearly about the same time, as has sometimes happened, — the effect on the foreign exchanges, though considerable, is seldom thought of. A foreign loan is usually taken out, — a large part in goods, another part in bills, and the balance most probably in specie. But the effect of a foreign loan on the *E*. is exactly the same as if the borrowing country had exported produce to the lending country equivalent to the amount of the loan, placing it in debt to that amount. The lender has become bound by contract to pay so much to the borrower. The whole weight of a foreign loan, therefore, falls at once to what may be called the adverse *E*. of the lending country or the favorable or less unfavorable *E*. of the borrowing country. The reverse action comes in half-yearly or yearly rills, when the interest and redemptions of

the loan, spread over a series of years, are payable. A foreign loan, if prudently and honorably conceived, may thus, as regards even the rate of *E.*, be advantageous on both sides. The lending country gives a great advantage at once to the borrowing country in its *E.*, which may be no evil in itself, and which the borrowing country, if the terms of the loan be fulfilled, repays in a period of years, during which its exporting and paying power may be reasonably expected to increase, which may be a common good. It may be added that foreign loans and investments of capital in foreign countries, badly as many may have been conducted, yet in their product of sound and marketable stocks and shares come to play a generally useful part in the rates of *E.* The value of commercial bills might not be so equable between such centres as New York and London, or New York and Paris, without the intervention of stock-*E.* securities. — 3. *Rate of Interest.* It is obvious that the number of days or months a bill has to run before payable imports the question of interest as an element of valuation in the rate of *E.* The usance of foreign bills is extremely various, from short to long, from payable at sight to payable at six months after sight; and days of grace are allowed by the law or custom of some few countries considerable enough to be taken into count. Where a bill is payable so many days or months after sight, the time that must elapse, in the ordinary course of communication, before it can be presented for acceptance, is a further prolongation of the currency of the bill. The buyer takes it with this weight of time upon it, and, whatever the period may be, is entitled to a concession equivalent to the interest of the money which he pays, the converse happening in the case of stocks and shares on which dividend or interest has accrued at the period of sale, and must be accounted for to the seller in the price. But the important question in foreign bills of *E.* is what rate of interest is to rule in the transaction. Is it that of the country where the bill is drawn, or the country where it is payable, or a compromise between the two? The drawer, in offering to transfer his bill to a buyer, is wholly in the domain of the rate of interest in his own market. If he sells, he gets the value of the bill in money worth so much interest; and if he holds the bill till its maturity, or to some period nearer its maturity, he deprives himself of money for that period worth the same interest. The buyer who in the event of an *E.* pays down the value of the bill in money would seem to be under the same condition; but in reality, when closely examined, the relations of the buyer and the seller of a bill of *E.* to the rate of interest are different. The buyer has a debt to pay in the country on which the bill is drawn, which debt he is bound to pay now; and for his purpose the bill is all the more valuable the less weight of interest it bears, or, in other words, the less discount it is subject to. Supposing, therefore, the bill is drawn in a country where the rate of interest is 7 per cent on a country where the rate of interest is 3½ per cent, possession of the bill will be more profitable, as regards rate of interest, to the buyer than to the seller. If the seller holds the bill, it bears 100 per cent more weight of interest than it would bear in the hands of the buyer. If the rates of interest in the two countries be exactly reversed, the bill bears 100 per cent more of this weight in the hands of the buyer than of the seller. Thus, after the par of the currencies has been established, which, as we have seen, is always practically established, even in the

case of an inconvertible paper currency, by the bullion test, and must be regarded as the first condition of all foreign *E.*, this question of interest is sufficiently important to modify the action of supply and demand, and of other circumstances operating either to raise the rate of *E.* above or depress it below the par of the currencies. It is one of those innumerable commercial relations in which there is an advantage to buyer or seller, but which cannot be realized without mutuality, and which consequently helps them to a transaction. If the advantage of rate of interest be in favor of the buyer of a bill of *E.*, he will be inclined, other elements of valuation considered, to give a somewhat larger price for it than if this were not in the account; and if the advantage be in favor of the seller he will be less exacting. The whole advantage on either side may not be realized in the actual terms in either case; but it will have had some effect towards a mediation of prices. — The price of a bill, apart from other elements, is the sum of the bill *minus* the interest it bears at the rate of discount in the country where it is payable. Yet in the practical negotiation this does not hold exact, because the value of the bill to the seller or the buyer is always modified by the relation of the rate of interest where it is payable to the rate of interest where it is drawn. — Rate of interest, though in the aspect it presents to the seller and buyer of a bill thus plain enough, yet comes to play so great a part in the general course of *E.* that it is worth while to pursue the subject a little further. Rate of interest regulates the supply and demand of bills, and affects the rate of *E.* through that element; where the balance of indebtedness is against a country and advance of the rate of interest tends to restrain imports and to stimulate exports, by which effects the balance of debt is reduced; and where the action of trade is not sufficient to overcome the evil, further rises of the rate of interest may be employed to attract imports of foreign capital and specie. In the case we have supposed of two countries, where the rate of interest is 100 per cent more in the one than the other, this relation of their rates of interest may be normal relation from the greater abundance or the greater profits of capital in the one than the other, and their *E.* may be supposed to be in equilibrium, so that this normal relation is not disturbed by any changes of rate of interest to correct the supply and demand of bills, or the balance of trade. The effect, as we have seen, of difference of interest was in favor of the price of the bill drawn by the country of high interest on the country of low interest, from the fact that the buyer was moving the bill out of a market where it bore a weight of 7 per cent to one where it bore a weight of only 3½ per cent interest. But suppose that the balance of indebtedness has become so adverse to the country of low interest that the rate has been increased to 7 per cent in order to improve the course of *E.*, and that the effect has been to render the foreign drawer less eager to sell his bill, and the foreign remitter more eager to buy it. The remitter or buyer will find the new influence thus introduced operating in the same direction, — viz. in favor of the price of the bill; but, on the other hand, the difference of interest has disappeared. Two effects have thus proceeded from the same cause, which neutralize each other so far as they go; and the remitter, instead of buying a bill, may as well, as regards the rate of interest in the two countries, be drawn upon by his foreign creditor. If the rate of interest be further increased to 10 per cent,

the drawer may be induced to hold the bill in order to save the 3 per cent of discount above the rate of interest in his own market; or an investing buyer may intervene, and give such a price for the bill as will allow the seller  $1\frac{1}{2}$  or 1 per cent of the profit, and leave  $1\frac{1}{2}$  or 2 per cent to himself. In either case the bill would be held till it matured, and relief to that extent be afforded to the *E.* of the country raising its rate of interest. But it is clear that not until the rate were raised 3, 4, or 5 per cent above the rates of the countries drawing upon it could any effect of this kind be produced. It thus appears that the function of rate of interest in controlling the supply and demand of bills is a strictly limited function; and this limitation will probably be found in all the effects expected from it on the state of *E.* It may hasten the course of payments due to a country, but it does not lessen the adverse balance of indebtedness, nor can it much retard the pressure of the foreign claims. It may restrain importation of foreign goods, but it may not at the same time increase exportation of domestic goods; or, if increasing export, it may not diminish import. These are results which will depend on many other causes. It may tend to lower prices, and thus seem to check import to the cost of production and exchange; it may render much outward as well as inward trade less possible. If the rate of interest be carried high enough; it may attract much capital from neighboring countries. Foreign bankers and lenders will buy up bills on the country as the best mode of importing their capital, or may import specie; and admirable as this service may often be, yet it does not lessen the foreign indebtedness of the country. It only transmutes one form of the adverse balance into another more convenient for the time being, and in the mean while, if the high rate of interest has crippled the productive and exporting resources of the country, little good or a reverse balance of evil may have been done. Hence, bullion reserves are either inadequate in the plan of their formation, or they miss their use and efficacy if, when a heavy balance of indebtedness appears in the *E.*, they cannot be treasured upon without large and excited advances of the rate of interest. — 4. *Cost of Specie Remittance.* Nothing is more definite in the system of *E.* than what has been more than once stated in the course of these remarks, namely, that the cost of remitting specie forms the limit of variation in the rates of bills. That the buyer of a foreign bill will not give more for it than the cost of remitting specie equal in amount to his foreign debt, is an axiom which holds good under all the ordinary conditions. But there are exceptions to the rule where the conditions vary from the ordinary. From the countries of productive gold and silver mines bullion flows abroad as naturally as the corn, cotton, wine, or oil, which forms the special merchandise of a country, and it will so flow irrespective of supply and demand of bills, rate of interest, and other causes which have so much sway in rates of *E.* San Francisco will export gold and silver to London in all states of supply and demand of bills, and when its rate of interest may be double that of the Bank of England, and in the common parlance money is there dearer than in London, though it may be only that the average profits of capital are larger in the one place than in the other. If bullion is needed at New York, and commanding a higher premium on the national currency, it will be matter of calculation to the bullion exporter at San Francisco whether to send a consignment to New

York or to London. If, since the discovery of the California mines, a metallic currency had been established throughout the United States, they would no doubt have absorbed a proportion of the gold and silver shipped to Europe; but, this object accomplished, the export to Europe would have proceeded much as it has been proceeding. In short, from gold and silver producing countries the export of bullion is not a remittance of money, but a transmission of the exportable produce of labor, which but for export would not have been produced. Then, there is the case of *E.* between countries of silver standard and countries of gold standard, from either of which remittances of specie cannot be made without exact reference to the market value of the two metals. This will have been already marked in the par of *E.* between the gold and silver country, but it will have introduced a new element into the cost of remittance, since the specie remitted will have to be sold into the specie standard of the country to which it is remitted. — In exchange between a gold-paying and a silver-paying country, one of which, say the silver country, has gone largely into an inconvertible paper currency, the case becomes more complicated, and the specie limit to adverse rate on bills recedes, till, if the inconvertibility be so great as to be incapable of valuation, or the government in its ignorance or alarm has prohibited the export of specie, the limit is wholly lost. A Russian merchant, who has ample silver and paper roubles at command for his purposes, but has a debt to discharge in the U. States, or needs to lift a cargo of cotton at Liverpool or of sugar at Glasgow, and finds that the remittance even of such specie as he may be able to produce is illegal, must buy a foreign bill or a banker's draft on London at any price. At this stage the rate of *E.* passes out of the domain of principle, or natural action of principle, into that of purely arbitrary considerations. When, from much less sufficient causes, general discredit passes upon a country, the rate at which its bills or acceptances may be valued is scarcely more reducible to rule. It might even be difficult to define why, in the same general circumstances, there should be collaterally a higher and lower course of *E.*, and the bills drawn or payable by one firm should differ in their rate from those drawn or payable by another firm. It is only by removing abnormal conditions that one arrives at the underlying principle which governs *E.* and determines the success with which it is conducted. — Accordingly it is in countries where bullion, separated from its necessary export from the mines, has become money, and forms the common standard of value in their international trade, that the limitation of the rate of *E.* by the cost of specie remittance is most clearly visible. Between all nations trading on a gold basis there is a well-known and definite point above and below the par of *E.* where it becomes profitable to move gold from one to the other, and which marks the extreme range of variation in the price of bills. Thus in the exchange of London with Paris, New York, and Berlin, respectively, 25.10, 4.81, and 20.30 mark a point in the price of bills below par when it pays to send gold from London to these centres; and, on the other hand, 25.30, 4.87, and 20.50, a point above par when it becomes profitable to move gold from Paris, New York, or Berlin to London. — When the rate of *E.*, touching, under the supply and demand of bills and other elements of valuation, these extreme points on one side or the other, and tending to exceed them, is the result of an actual over-indebtedness, a transmission of bullion

is the best and most satisfactory mode of settlement. It directly reduces the balance of debt, and renders the price of bills again more equitable to traders. All other modes of fencing it off, save an increased export of goods and produce, are more or less illusory. If, in such a juncture, an amount of foreign capital has been invested in bills on the country with the view of holding them to maturity for sake of profit in rate of interest, and now, with the view of realizing the value of the bills in gold, they should be pressed on the market before maturity for discount, an advance of one per cent in the rate of discount may be sufficient to induce the foreign capitalists to hold the bills till they mature. And another advance of one per cent in the rate of discount may induce them to reinvest in other bills on the country. But the root of the adverse *E.* will not have been removed. It will always appear when the foreign capital thus invested in bills on the country is from any cause withdrawn, and until the over-indebtedness is liquidated by remittances of specie, increased export of produce, or transfers of salable shares and securities. If, on the other hand, the rate of *E.* has been brought to the specie limit by bills representing no actual debt, but drawn and accepted solely for the purpose of moving bullion, as may probably happen, there is no remedy for what may prove an inordinate demand for specie by irregular means but the detection of the bills, and either refusing them discount, or discounting them under exceptionally high rates of interest. — 5. *Correct Judgment, or its Opposite, Panic.* An exposition, however brief, of the causes operating on the rate of *E.* would scarce be complete without including the effect of opinion or estimate, correct or erroneous, of the probable course of the market; and therefore it may be observed that a judgment has to be formed in every new phase of the numerous fluctuations. The seller of bills finds that within a few days the market has taken an unfavorable turn. If he judges that this has arisen from merely accidental or temporary causes, he will be inclined to hold his bills for what he deems their true value; or if, on the contrary, he judges that the causes operating are more deeply seated, and likely to become stronger for a time, he will sell with the least possible delay. Should his judgment be justified by the event he will have done what is right for him, if otherwise he will have done what is wrong; but in either case his abstention or action will have affected the supply and demand of bills in the mean while. In all the great marts of *E.* there are frequent wave-currents, so to speak, which cannot be rightly interpreted either as the sign of a protracted state of *E.* between the points of the compass in which they flow, or of the general foreign indebtedness of the centre upon which they are directed. When New York balances its debts to China and India by bills on London, the bills affect the course of eastern *E.*; but they lose much of the significance they might otherwise bear when it is considered that New York is in course of compensating London in other directions. These operations come to be understood and systematized by dealers and agents in bills with much accuracy; but in addition to the judgment that may be formed by a thorough analysis of the substance of the various currents of *E.* there is the effect of opinion on external events, which, though of almost daily occurrence in one quarter or another, are wholly of future account, and which impress not only the connoisseurs of *E.* but the whole body of drawers and remitters, from whom the

original impulse on the action of *E.* in all cases comes. The examples that might be adduced of the great effect of passing events on *E.* are innumerable. In the beginning of 1861, when the rupture between North and South had occurred, and war was imminent, the U. States had a most favorable balance of trade with England and Europe. Their exports of wheat and flour and cotton in the previous year had at once reached a maximum in quantity and a rise in value. The drawer of a bill on London was in so good a position that he had only to wait for the buyer to get the value of his bill up to the specie point. But so eager were the drawers, in view of the pending outbreak of civil war, to realize what was owing to them abroad, that they threw their bills on the market in an abundance which reduced their price to the other end of the scale. This, of course, had its converse effect at London, and bills on New York were there selling at such a premium that it seemed as if the U. States would have to remit bullion to Europe. The volume of bills, however, told its own tale after a while. England had to remit bullion in large quantity to the U. States, and then people began to awake to the perception that, in the *E.* transactions, the one element most important of all had been left out, — namely, the relative indebtedness. It must have been a time of much profit to those on both sides of the Atlantic who knew the actual state of affairs, and of much loss to those who did not know, of whom there can be little doubt that the latter were much the greater number; but the balance of value between the two countries, as expressed on the face of the bills, had to be rendered all the same. To take a more recent case. The *E.* value of the Russian rouble during the last twelve months of war between Russia and Turkey will amply illustrate what is meant by the prevailing judgment on events in their future aspect, which, while proceeding on a certain amount of reason, yet borders on panic, and may be of the nature of panic. The issue of paper roubles had gone the length of 750 millions before the war, and there was a constantly increased remission during the year, counteracted in some measure by conversions into loans bearing interest. On the mobilization of the troops the value of the rouble was 58 cts. to 60 cts.; on war being declared it fell to 54 cts.; when it seemed as if Plevna could not be taken it sank to 45 cts.; when Plevna fell it rose to 53½ cts.; and when it followed that the conquest of Turkey and an armistice did not end the difficulties, it fell to the lowest point it had touched, 44½ cts. — *Favorable and Unfavorable E.* The term, "favorable *E.*," as commonly used, not only means a state of the *E.* when the debts due to a country abroad are so much greater than what it owes abroad as to affect potentially the demand and supply of bills, and when the money of the country so situated, as expressed in the price of bills, is equal to more of the money of a foreign country than the nominal par, — when its bills on abroad, in short, are dull of sale, while the foreign bills on itself are in much demand; it is also applied to all stages, moderate or extreme, of this relation of the foreign *E.* And so the term "unfavorable," of course, applies to the opposite conditions. If these phrases had ever any reference to the prosperity of the foreign trade of a country, they must have arisen under the sway of "the mercantile system" of the last century, the principle of which was that a balance payable in specie is the cardinal condition of prosperous trade with any foreign country; or, if introduced under that erroneous theory, they have

been prolonged by the usage of bankers and other dealers in foreign *E.*, who, having large liabilities entailing bullion payment, naturally consider a state of *E.* which is on the eve of bringing specie more favorable than one on the eve of taking it away. This is quite true in the monetary view of the question, and it is true also as to the relative indebtedness for the time being. But it is not true to extremes, even in a monetary sense. The condition of a country to which specie was always flowing in and never going out would be a realization of the fate of Midas. The most favorable *E.*, therefore, is that where there are only moderate oscillations up or down from the par of *E.* While the terms "favorable" and "unfavorable" are thus somewhat misleading as regards substantial interests, they are involved in a minor technical complexity, which, though well understood by those in the business, may here be stated. The terms would be strictly applicable in the sense they are used, were the rate of *E.* always quoted in the home money. The *certain* properly in *E.* transactions is the number of pounds, dollars, francs, or florins a remitter has to pay abroad; the *uncertain* is what amount of his own money is equal to this amount of the foreign money. Were the quotation on both sides respectively always made in the home money, the fall or rise of the quotation would always be identifiable with such terms as "favorable" or "unfavorable." Both drawers and remitters would be so familiar with their significance as to know what they meant. But this is not the practice, and, with so much variety of currency, could hardly have been the developed practice, of *E.* The pound sterling of England is the largest monetary unit, and there is always facility of expressing minute shades of difference in the smaller units, more especially when, as in the case of Paris or New York, they have a decimal character. In London, consequently, the public only hear quotations of rate of *E.* with such countries as France and the U. States in the foreign money, — London thus giving what is called the *certain*, and the smaller moneys the *variable*. On the other hand, not only in the Australian and other British colonies, where the standard of value is the same as in the parent country, but in such large commercial regions as China and India, the quotation of rate of *E.* on both sides is always expressed in sterling. The Chinese tael of silver is worth so many English pence sterling at Canton; and the rupee is worth so many English pence at Bombay or Calcutta; and in the same terms run the quotations in London. The practice may not alter in any iota the true rate of *E.*, but it has the result that when the rate is quoted in sterling money, as in the Indian, Chinese, and Australian *E.*, every drop in the quotation is "more favorable" to England, every rise "less favorable," and this will hold good whether the quotations are made in England or in India, China, or Australia; whereas, on the other hand, when *E.* are quoted in other money — American, French, or German, etc. — every drop in the rate by the same rule is "less favorable," every rise in the rate "more favorable," to England, whether the quotation be made in England or in the foreign countries. The states of *E.* to which the terms "favorable" and "unfavorable" are thus applied refer wholly to the effect of the demand and supply of bills; so that, since the fluctuations of *E.* are due to various causes, it would be an improvement were the quotations always to include the par of *E.*, whether between the gold money of one country and the silver money of another, or

between either and inconvertible paper, the depreciation of which has to be determined by the gold or silver premium in the country of its currency. The actual rate above or below par would show the effect due to the supply and demand of bills. When a sudden alteration takes place in foreign *E.* nothing is more difficult than to discover the relative force of the cause or causes to which it is to be ascribed, and yet nothing is more necessary to know than this, whether in the correctives that may be applied or in the lessons to be conveyed to importers and exporters.

*Negotiation of Bills of E.* Rates of *E.* have undergone much variation of late years from changes of standard, — in some cases from gold to silver, and in others from silver to gold, — and from the circulation of forced paper currency. The tendency, however, is to greater uniformity. The gold standard of value adopted at Berlin extends to the whole German Empire, and the rates of *E.* are now calculated in imperial marks and pfennig at Hamburg, Frankfurt-on-the-Main, Altona, and other German places, where different moneys formerly were used. The money under the new system is 100 pfennig = 1 mark, 20 marks = 1 twenty-mark gold-piece (imperial mark) = 19s. 6.954 sterling mint par. The mark, which is the unit or integer of the system, is a silver coin based on the ratio of 1 to 15½ as the relative value of silver and gold. In like manner the kingdom of Italy has extended a uniform *E.*; and the rates at Naples, Palermo, Messina, Milan, Turin, Florence, Leghorn, and other Italian towns are similar to the rates at Genoa. — Bills of *E.* on New York and in other large cities of the U. States are bought and sold through brokers, who go round the mercantile and banking houses, and discover whether they are buyers or sellers of bills. In New York, as in other great commercial cities, bankers deal largely on the rise and fall of *E.*, — buying bills when they expect a rise, and selling bills when they expect a fall. — *E.*, as regards the abundant arithmetic to which it gives rise in its negotiation, may be divided into (1.) Direct, or *E.* between two countries wholly based on their rates of *E.*, which is so simple as to need no remark; (2.) Cross, or *E.* between two countries in which a third country has an interest, as when London, say, has 10,000 francs in Paris which he wishes to move to Hamburg, and has to take account of his own course of *E.* to Hamburg, as well as the direct between Paris and Hamburg, which is only less simple than direct exchange, inasmuch as it requires two formulae instead of one; and (3.) Indirect or arbitrated, where *E.* between two countries is conducted through the medium of a third, or more than one other country, and thus becomes more compound as the sphere of the operation is extended. It is an arbitrated rate because it has no actual form, and is found only in figures out of the current rates of *E.* between more than two countries. The object being to discover how a debt in one place may be most economically paid from another, the question carries along with it not only the difference between remitting and drawing which exists in the simplest direct *E.*, — the debtor in the one country and the creditor in the other having always the option of the one remitting or the other drawing, — but such *minutiae* as whether the rate of *E.* given be in the foreign money or in sterling, till it results in the following rules: —

"For Remittances: —  
"With a foreign rate, any arbitrated rate is better than the direct rate if it is *greater* than the latter.

"With a sterling rate, arbitrated is better than the direct rate if it is *less* than the latter.

"Because, in either case, a given sum in sterling will produce a greater sum in foreign money, or a given sum in foreign money will cost a less sum in sterling.

"For Drafts or Returns: —

"With a foreign rate, any arbitrated rate is better which is *less* than the direct rate.

"With a sterling rate, any arbitrated rate is better which is *greater* than the direct rate.

"Because, in either case, a greater sum in sterling will be obtained from a given sum drawn for in foreign money."

Nor is this all. Arbitrated rates are calculated for present money: the actual rates of *E.* on which they are calculated have been affected by time and rate of interest. In the rate of direct *E.* particularly, with which the arbitrated rate has to be compared, this effect has to be estimated, long bills reduced to short, and the difference of interest on them discounted from the basis of calculation *prima facie*. This, in a superficial view, may be counterpoised by drawing speculative bills of long date on a foreign centre; but there are limits to drawing on a place for purposes external to its ordinary course of *E.*, and a large amount of bills thus directed without corresponding remittances might produce an effect on the *E.* which would go far to upset the calculation. — It is obvious that arbitration of *E.*, thus burdened at every additional length of the chain by difficulties of estimate, cannot be much extended, or become too artificial, without the risk of miscarriage. But the mediation of direct *E.* through a third place is of such com-

mon and useful practice that it may be desirable to give an example broad enough to illustrate the general method of equation.

Take London on Paris at 3 months, quoted f. 25.55: Paris on London at 3 months, quoted f. 25.10.

The discount for 3 months, in the example to be given, is taken at 1 per cent, or 25 cen., which is deducted from the London rate, and added to the Paris rate, to make the two short or cash rates; thus reducing the former to f. 25.30, and raising the latter to f. 25.35.

#### EXAMPLE.

From the following rates of bills in London and Paris, it is required to find, —

1st. Whether, having money to transmit from London to Paris, it will be better for me to remit direct bills on Paris, or to order bills in Paris to be drawn upon me in London, at the rate of 4 per cent per annum.

2d. Whether, having money to draw from Paris, it will be better for my correspondents there to make me remittances, or for me to draw upon them.

3d. If I have to make remittances to Paris, whether any indirect rate will answer better than the rates of direct bills.

4th. If I have to obtain returns from Paris, whether any indirect rate will answer better than either of the direct rates.

#### RATES OF EXCHANGE.

London, June 17.	Paris, June 14.
25.55 ..... Paris at 3 months.	
12 <sup>11</sup> / <sub>16</sub> ..... Amsterdam ..... 209}	
13 <sup>10</sup> / <sub>16</sub> ..... Hamburg ..... 184	
121 ..... Frankfurt ..... 210}	
29.47 ..... Leghorn ..... 15 loss = 100 lire for 85 francs.	

#### METHODS OF WORKING THE EQUATIONS.

##### Amsterdam.

£1?  
100 = \* 12<sup>11</sup>/<sub>16</sub> Florins and Stivers.  
Francs 2.09  $\times$  12.06  $\frac{1}{2}$  = 25.24 Francs.

##### Hamburg.

£1?  
Sc. 100 = Mk. 100 = \* 184 Francs.  
Francs 184  $\times$  218  $\frac{1}{2}$   $\div$  1000 = 25.10 Francs.

##### Frankfort.

£1?  
100 = \* 121 Florins.  
100 = \* 210  $\frac{1}{2}$  Francs.  
Francs 210  $\frac{1}{2}$   $\times$  1.1  $\div$  1000 = 25.42 Francs.

##### Leghorn.

£1?  
1 = \* 29 47  $\frac{1}{2}$  Lire Italiane.  
100 = \* 85 Francs.  
Francs 85  $\times$  29 47  $\frac{1}{2}$   $\div$  100 = 25.06 Francs.

#### COMPARISON OF THE ARBITRATED RATES.

	Prices.		Paris.
	London.	Paris.	
London, 3 months.....	25.55		25.30 short.
Amsterdam.....	12 <sup>11</sup> / <sub>16</sub>	209	25.24
Hamburg.....	13 <sup>10</sup> / <sub>16</sub>	184	25.10
Frankfort.....	121	210 $\frac{1}{2}$	25.42
Leghorn.....	29 47 $\frac{1}{2}$	85	25.06
Paris, 3 months.....		25.10	25.35 short.

#### FOR DIRECT PAPER.

It appears from the direct rates between London and Paris at 25.30 and 25.35 that, —

1st. To remit or transfer money from London to Paris, it is better for Paris to draw upon London at 25.35 short, than for London to remit to Paris at 25.30 short, because by the former operation there will be made 5 cents per pound, or about one fifth per cent, more than by the latter.

2d. To have returns from Paris, it is better, by the same 5 cents, for London to draw upon Paris than for Paris to remit to London, because the bills will cost so much less French money, or produce so much more in sterling.

#### FOR INDIRECT PAPER.

1st. For remittances to Paris, it appears from the arbitrated results that bills on Frankfort, bought in London at 121 florins per £10 sterling, and sold in Paris at 212 francs per 100 florins, will produce 12 cents more than direct remittances from London to Paris, or 7 cents more than is yielded by direct drafts of Paris upon London.

(Continued at beginning of next page.)

#### PARS OF EXCHANGE IN THE U. STATES.

(Since Jan. 1, 1879, the following rates are taken by the U. States Custom-House in estimating the value of all imported merchandise.)

COUNTRY.	Monetary Unit.	Standard.	Value in U. S. money.	Standard Coin.
Austria.....	Florin.....			8 Gulden, or 20 Francs, gold, =
Belgium.....	Franc.....	Gold and Silver.....	0.193	5, 10, and 20 Francs. (83 8689
Bolivia.....	Dollar.....	" ".....	0.965	Escudo, $\frac{1}{2}$ Bolivar, and Bolivar.
Brazil.....	Milreis of 1000 Reis.....	Gold.....	0.545	None
British Poss. in N. A.....	Dollar.....	" ".....	1.	
Bogota.....	Peso.....	" ".....	0.965	
Central America.....	Dollar.....	Silver.....	0.935	Dollar.
Chili.....	Peso.....	Gold.....	0.912	Condor, Doubloon, and Escudo.
Denmark.....	Crown.....	" ".....	0.268	10 and 20 Crowns.
Ecuador.....	Dollar.....	Silver.....	0.935	Dollar.
Egypt.....	Pound, 100 Piastres.....	Gold.....	4.974	5, 10, 25, and 50 Piastres.
France.....	Franc.....	Gold and Silver.....	0.193	5, 10, and 20 Francs.
Great Britain.....	Pound Sterling.....	Gold.....	4.894	4 Sovereign and Sovereign.
Greece.....	Drachma.....	Gold.....	0.193	5, 10, 20, 50, and 100 Drachmas.
German Empire.....	Mrk.....	Gold.....	0.238	5, 10, and 20 Marks.
Japan.....	Yen.....	" ".....	0.997	1, 2, 5, 10, and 20 Yen.
India.....	Rupree of 10 Annas.....	Silver.....	0.444	
Italy.....	Lira.....	Gold and Silver.....	0.193	5, 10, 20, 50, and 100 Lire.
Liberia.....	Dollar.....	Gold.....	1.00	
Mexico.....	Dollar.....	Silver.....	1.015	[taro.
Netherlands.....	Florin.....	Gold and Silver.....	0.385	Peso, or Dollar, 5, 10, 25, and 50 Cen.
Norway.....	Crown.....	Gold.....	0.268	Florin, 10 Gulden, gold, = 84.0100
Peru.....	Dollar.....	Silver.....	0.935	10 and 20 Crowns.
Portugal.....	Milreis of 1000 Reis.....	Gold.....	1.08	2, 5, and 10 Milreis.
Russia.....	Rouble of 100 Kopecks.....	Silver.....	0.748	1, $\frac{1}{2}$ , and 1 Rouble.
San Iwich Islands.....	Dollar.....	Gold.....	1.00	
Spain.....	Peseta of 100 Centesimos.....	Gold and Silver.....	0.166	5, 10, 20, 50, and 100 Pesetas.
Sweden.....	Crown.....	Gold.....	0.268	10 and 20 Crowns.
Switzerland.....	Franc.....	Gold and Silver.....	0.193	5, 10, and 20 Francs.
Tripoli.....	Mahbub of 20 Piastres.....	Silver.....	0.844	
Turkey.....	Piastre.....	Gold.....	0.043	25, 50, 100, 250, and 500 Piastres.
U. S. of Colombia.....	Peso.....	Silver.....	0.335	

21. For returns from Paris, it appears from the arbitrated results that bills on Leghorn, bought in Paris at 85 centimes per paper lira Italiana, and sold in London at paper lira Italiana 29.47½ per pound sterling, will cost 29 cents. less than direct bills from Paris, and will give 24 cents. more than drafts from London on Paris.

Such is the manner in which the various *E.* are calculated in order to ascertain which will answer best for a speculation in bills through intermediate places. The contingency of a change of rates has to be considered, and the charges of brokerage and commission on the operation have to be deducted from the result, or may be reduced when the operation is done by branches of the same house, or on joint account. The elasticity of arbitrated rates of *E.* is put to the severest strain when a large subsidy, or monster indemnity, like that of France to Germany, has to be paid by one country to another. In these cases it is necessary to employ extensive banking co-operation, and at centres on which the drafts are heavy to arrange means for the support of the *E.* — *R. Somers.*

**Exchange**, a place of public resort, in commercial cities, where merchants meet to transact business. In New York and other cities of the U. States there are also Corn *E.*, Cotton *E.*, etc. — The bartering of one commodity for another.

**Exchange Broker**, a person whose business is to propose and conclude bargains between merchants and others in matter of bills of exchange. They make it their business to know the state of the exchange, and the circumstances likely to elevate and depress it. They sell bills for those *drawing* on foreign countries, and buy bills for those *remitting* on them; and from their knowledge of the mutual wants of the one class compared with those of the other, a few of the principal brokers are able to fix the rate of exchange at a fair average, which it would not be possible to do if the merchants directly transacted with each other. They receive a small commission.

**Exchange Dealer**, a person, more usually a banker, who buys and sells foreign bills of exchange.

**Exchange Fire Insurance Co.**, located in New York City, organized in 1853. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$200,010; net surplus, \$119,693.49; total cap. and surplus, \$319,703.49; risks in force, \$18,903,772; premiums, \$91,139.06; premiums received since the organization of the Co., \$2,440,245.98; losses paid, \$1,433,239.98; cash dividends paid to stockholders, \$242,617.50.

**Exchequer Bills** are promissory notes issued by the English Treasury under the authority of Parliament; and are the form in which the floating or unfunded part of the English national debt chiefly exists. The issue of these bills greatly facilitates the current financial business of the government. They are circulated at present for sums varying from £100 to £1,000, which are printed with ink of different colors; namely, £100 bills with red; £200, yellow; £500, blue; and £1,000 bills with black ink. They bear interest from their date until the day fixed for their payment, which is announced by advertisement, and is generally about a year after being issued, when they are either discharged or renewed for other bills, at the option of the holders. Parties neglecting to present their bills on the day appointed are deprived of interest till the next opportunity of obtaining new bills, or else must submit to the loss of whatever premium they may chance to bear at the time. During the currency of these bills they may, after a limited time, be paid to the government at par in discharge of duties and taxes; they are thus nearly exempt from the risk of depreciation, and, as they are transferable without the necessity of a formal assignment, they form an eligible investment for capital that may require to be suddenly made available. They are so much in

demand by capitalists in the metropolis, that government is enabled to keep a considerable amount of them, generally about £28,000,000, in circulation at a low rate of interest. The rate is fixed at so much per cent per diem, and is commonly adjusted so that the bills shall bear a premium in the market, in order that government may not be exposed to the inconvenience of having them returned in payment of taxes. Of late years the rate has fluctuated from 2½*d.* to 1*d.* per cent per diem; that is, from £3 16*s.* 0½*d.* to £1 10*s.* 5*d.* per cent per annum.

**Excise**, in England, an inland tax or impost on certain articles of home manufacture and consumption, as on beer, British spirits, malt, etc. The excise also grant licenses for certain trades and occupations which bring in a duty to government. See INTERNAL REVENUE.

**Exorcitation**, the stripping off the bark of a tree.

**Execution**, a judicial writ issuing from some court of law against the body, lands, or goods and chattels of a person.

**Executor**, a person appointed by the testator to administer to his estate, to carry into force the appropriations of his will and testament after his decease.

**Exemplaire** [Fr.], a copy of a book or engraving.

**Exempt**, privileged; free from charge or duty.

**Exequatur**, an official recognition of a consul or consular agent, authorizing him to act in a country.

**Exhibit**, any voucher or document produced in a court of law, or before arbitrators, etc. — The written statement of the affairs of a merchant in failing circumstances, or of one who has suspended payment.

**Exhibition**, a public display of works of art, industry, manufactures, etc. See NATIONAL AND INTERNATIONAL EXHIBITIONS.

**Ex-Officio** [Lat.], by virtue of the office.

**Exotic**, a plant or product of a foreign country.

**Expansion**, all substances, solid, liquid, and gaseous, when chemical change does not take place, expand by heat and contract by cold. In some of them this property occurs in a greater degree than in others, but is constant for the same substance under the same circumstances. The chemist avails himself of this property in the construction of his thermometer; the wheelwright, in fixing on the tire of his wheels; the engineer, in restoring to the perpendicular the leaning walls of buildings, etc. This *E.* by heat is of great importance in the manufactures, as allowance has to be made of it in every purpose where metals are employed. The following is a list of the *E.* of the chief metals, etc., when heated from 32° to 212° F., or from 0° to 100° Cent.: —

Substance.	Expansion.	
	In bulk.	In length.
Glass.....	1 in 384	.....1 in 1150
Platinum.....	1 " 377	.....1 " 1311
Steel.....	1 " 309	.....1 " 926
Iron.....	1 " 282	.....1 " 846
Gold.....	1 " 227	.....1 " 682
Copper.....	1 " 194	.....1 " 582
Brass.....	1 " 179	.....1 " 536
Silver.....	1 " 175	.....1 " 524
Tin.....	1 " 172	.....1 " 516
Lead.....	1 " 117	.....1 " 351
Zinc.....	1 " 113	.....1 " 340

Of the liquids, they expand as follows, when heated from 32° to 212° F., or from 0° to 100° Cent.: —

Mercury.....	1 in 55 in bulk
Water.....	1 " 21 "

Gases practically all expand alike; that is to say, for every degree F. a gas expands  $\frac{1}{481}$  of its bulk at  $32^{\circ}$ , and for every degree Cent.  $\frac{1}{273}$  of

Fig 168.—COMPENSATION PENDULUM.

Compensation Pendulum (Fig. 168) consists of several rods of steel and brass, so arranged that their unequal capacity of *E.* produces a compensating result.

**Expansion-Joint**, the stuffing-box joint connecting the steam-pipes, so as to allow one of them to slide within the enlarged end of the other when the length increases by expansion.

**Expansion-Valve**, an auxiliary valve placed between the slide valve and the steam cylinder. It is worked by a cam or other contrivance, so as to cut off the steam at a given period, and cause the remainder of the stroke to be performed by expansion.

**Ex-Parte**, a partial or one-sided statement.

**Expectation of Life**, a phrase improperly applied by writers on Life Insurance to the average of forthcoming years in the life of an individual. As explained in the article INTEREST AND ANNUITIES, it is different from the term of probable life.

**Expedient**, a contrivance.

**Expenditure**, a charge or disbursement; outlay; that which is consumed or used on board ship is said to be expended.

**Experiment**, a trial or effort; an attempt to analyze or determine by a chemist.

**Expert**, a person skilled in handwritings; a facsimilist.—A person selected by a court, or by parties in a cause, on account of his knowledge or skill, to examine, estimate, and ascertain things, and make a report of his opinion.

**Exploitation** [Fr.], the improving of lands, the felling of woods, the working of mines, or other undertakings.

**Exportation**, the art of sending or carrying in traffic goods or productions from one country to another. See IMPORTATION AND EXPORTATION.

**Exporter**, a shipper of wares, commodities, or merchandise of any kind to a foreign country.

**Exports**, goods, wares, or manufactures transmitted abroad. See IMPORTATION AND EXPORTATION.

**Express**, a system organized in the U. States for the transportation of merchandise or parcels of any kind. This system was originated in 1839, when Mr. William F. Harnden, of Boston, proceeded to New York in charge of a few parcels, bank-notes, etc., for delivery in the latter city, and for which service he received an adequate remuneration. The success of this experiment led him to form a contract with the railroad and steamboat companies connecting the two cities, by which increased facilities were afforded him for the development of his scheme. In the next year a rival *E.* started under the auspices of Messrs. P. B. Burke and Alvan Adams, which eventually extended its ramifications throughout the U. States, and led the way for the formation of numerous other companies, specified at the foot of this article. The Burke and Adams *E.* became consolidated, in 1854, with other companies, and form the now celebrated Adams' Express Company. The general system upon which these companies conduct their extensive operations is sufficiently well known in this country to dispense with exposition here, even did the limits of our space admit of such. The following are the principal *E.* companies now in successful running, and their field of operations: *Adams' Express Co.* (E., W., and S. States); chief offices, New York, Philadelphia, and Boston. *American Express Co.* (N. and W. States and Territories). *American-European Express Co.* (Great Britain, France, and other parts of Europe, Asia, and Africa); principal offices, New York, Philadelphia, London, Liverpool, Paris, etc. *Central Express Co.*, an important concern, connecting with all others; chief office, Philadelphia. *Hocoma and West Indies Express Co.*, W. Indies, Brazil, and Eastern S. America. *Harnden Express Co.* (N. and E. States); chief office, New York. *Merchants' Union Express Co.* (N., E., and W. States); chief office, New York. *Pacific Mail Steamship Co.*, California, S. and Central America, China, Japan, and islands of the Pacific; Pier 42, foot of Canal street, New York. *Southern Express Co.* (S. States,—all S. of "Mason and Dixon's line"). *U. S. Express Co.*, N. and E. States, and the Canadas. *Wells, Fargo, and Co.*, California (overland), and W. Territories and the Pacific islands, etc.—*Zell's Encyclopedia*.

**Extension**, an agreement by which a creditor allows to his debtor further time for payment.

**Extra**, additional; superior; a term for the flour made of the best quality of red winter or low white wheat, with the fine flour and middlings bolted out. Double extra, or, as usually written, XX, is the choicest flour that is made from the best white wheat.

**Extract**, among chemists this term is understood to apply to the residuum of the evaporation of aqueous decoctions or infusions of vegetable matter. In *medicine* and *pharmacy*, it has a less definite signification, being applied to various preparations obtained by evaporating the expressed juices, or the decoctions, infusions, or tinctures of vegetable substances, until a mass of a solid or semi-solid consistence is formed. *E.* vary in their nature and composition with the sub-

stances from which they are prepared and the fluids employed as solvents. When water is employed as the menstruum, the products (*aqueous E.*) usually consist of gum, starch, sugar, albumen, extractive and saline and other matter, along with the peculiar principles on which the medicinal virtue of the vegetable depends. When spirit is employed as the solvent, the products (*alcoholic E.*) contain most of the substances above enumerated, except the gum and starch, together with several other substances which are soluble in spirit, but which are either wholly or nearly insoluble in water; as resins, essential oils, and the proximate principles of vegetables. These preparations, with scarcely an exception, are considerably more powerful than the aqueous *E.* of the same vegetables. In some cases proof spirit or under-proof spirit is employed, when the extracts (*spirituous E.*) generally possess properties between those of the above. In other cases, dilute acetic acid or acidulated water is employed as the menstruum, when the products (*acetic E.*) possess much greater activity than when prepared with water; and would in many cases prove fatal, if exhibited in doses as large as those of the aqueous *E.* Still more active *E.* are obtained by a combination of the two last menstrua. Either is sometimes used as the menstruum for the active principles of certain substances, as cantharides, cubebs, worm-seed, etc. (*etheral E.*). The term *simple E.* is applied to an *E.* prepared from a single plant or vegetable substance, and the term *compound E.* to one prepared from two or more of such substances. The *fluid E.* of modern pharmacy are those which are only evaporated to the consistence of a thin sirup, and then mixed with  $\frac{1}{10}$  to  $\frac{1}{2}$  of their volume of rectified spirit.

**Preparation.** The preliminary operations in the manufacture of extracts are similar to those employed in the preparation of *decoctions*, *infusions*, and *tinctures*. The proper quantity of the ingredients being taken, the whole is well bruised or reduced to coarse powder, or otherwise divided by slicing with a knife, that every portion may be fully exposed to the solvent action of the fluid. In some few cases (as with gentian, etc.) the "slicing," or reduction to fragments, is often conveniently deferred until the action of the menstruum shall have so far softened the ingredients as to render them of easy division by the knife. Those substances (as sarsaparilla, chamomiles, etc.) whose medicinal principles reside in the cortical portion, of which are of easy solubility, are commonly subjected to the action of the menstruum without being subjected to any particular preparation. — In the preparation of *aqueous E.* the ingredients are treated with water until all the soluble matter that it is desirable to obtain is dissolved out. There are several methods of effecting this object, depending upon the nature of the substances acted on. In some cases maceration in cold water is resorted to; in others, percolation with that fluid in a "displacement apparatus." More generally, however, boiling water is poured on the substance, and is digested on it for some time, as in the preparation of infusions; or the substance is exhausted by boiling in water, as in the preparation of decoctions. After the ebullition or infusion has continued a sufficient time, the heat is removed, and the liquid portion drawn off. The ingredients are then pressed to extract the remaining liquid; or they are washed or "sparged" with hot water, which expels it by displacement. According to the usual practice in the majority of cases, a second quantity of water is poured on after the first has been thoroughly drained off, and the effusion or decoction is repeated a second and even a third time, or until the ingredients are perfectly exhausted of their soluble portion. The liquor or liquors thus obtained being allowed to repose for 15 or 20 minutes, for the purpose of depositing the sand or other gritty and heavy matter that is mechanically mixed with them, are carefully decanted from the sediment, and, after being run through a fine hair sieve, or flannel bag, are ready for concentration. In some instances, however, this method proves insufficient to render the liquid clear. In such cases the solution may generally be rendered transparent by clarification with a little white of egg, removing the scum as it rises, straining the liquid through flannel, as before; or the liquid may be filtered through a bag made of fine "Welsh flannel," or of "twilled cotton cloth" (Canton flannel), both of which should be soaked in clean water for at least an hour

before use. In the small way, filters of linen or paper are sometimes employed; but as all media sufficiently fine to render vegetable solutions transparent soon choke up, this filtration is objectionable, from the length of time it occupies. In some houses the aqueous infusion or decoction is allowed to repose for 24 hours, and then is decanted and evaporated; but such plan is objectionable, as, however smooth and glossy *E.* so prepared may appear, their medicinal virtues are lessened by the lengthened exposure to the atmosphere. When about one half of an aqueous solution has evaporated, it is often advantageous to pass it through a flannel or horsehair strainer, to remove the flocculi that generally form by the action of the heat and air. This is especially necessary with vegetable solutions prepared without boiling, and should be adopted whenever a smooth and clear *E.* is desired. On the large scale, the evaporation of infusions or decoctions for *E.* is usually conducted in very wide, shallow, copper or tinned-copper pans, having steam-tight jackets of cast-iron, and heated by steam "playing" between the two. The rapid deterioration which vegetable juices and solutions undergo by exposure to the air, especially at high temperatures, has led to the introduction of apparatus by which they may be concentrated without contact with the atmosphere, and at a less degree of heat than is required for that purpose in open vessels. Such is the method, commonly called "Barry's process," in which the air is removed from certain air-tight refrigerators by the introduction of steam, which is then condensed by the application of cold, by which means a partial vacuum is obtained. Another process for attenuating the atmosphere over the surface of fluids during evaporation is by the action of an air-pump. This plan was introduced by Howard, and is commonly applied to the concentration of sirups in the sugar refineries. *E.* obtained by either of these methods are said to be prepared "in vacuo," and are found in practice to be immensely superior to the common *E.* of commerce. — *Alcoholic and spirituous E.* are prepared by evaporating a filtered concentrated tincture of the ingredients in any suitable vessel, by which the volatilized spirit may be saved. In general, rectified spirit is used as the menstruum; but in some cases proof spirit is employed; and in others, the substances are first digested in proof spirit, and afterwards in water, and the mixed tincture and infusion evaporated in the usual manner. — *Etheral E.* are obtained in a similar manner to alcoholic ones; but being merely prepared in small quantities at a time, the process may be conveniently performed in glass vessels. When it is required to boil either of the above fluids (alcoholic or etheral), or any other volatile liquid on the ingredients, a vessel fitted with a long tube, or a Liebig's condenser reversed, may be used to prevent any loss of the menstruum.

The quality of an extract cannot be ascertained by mere inspection, nor is it readily discovered by chemical tests. A knowledge of these facts has induced the mercenary and fraudulent manufacturer to employ damaged and inferior drugs in their preparation, alike regardless of the welfare of the patient and the credit of the practitioner. A common practice with some manufacturers is not only to pick out the least expensive variety of every drug for the preparation of their extracts, but the most inferior and often damaged and worthless portion of this already inferior article. The production of a smooth, bright, and glossy extract is all that is usually attempted by these individuals, and all that is sought after by the mass of purchasers, who mistake the simulation of the mere external signs of good quality for its actual existence. It is a fact, which we can verify from extensive experience in the laboratory, and from years of practical observation on this point, that extracts faithfully prepared from good materials do not possess the slightly and pleasing appearance of those commonly vended by the wholesale druggists. On comparing the extracts prepared by different metropolitan houses, we have found that those which have exhibited a remarkably bright and glossy appearance have been uniformly inferior, and sometimes nearly inert; whilst others, with a less prepossessing appearance, have been generally of good quality. These facts are well established by reference to the extracts of those houses and institutions that are remarkable for the superior quality of their preparations, and by comparing them with the common extracts of the shops supplied by the wholesale trade. — A good extract should be: 1. Free from grit, and wholly soluble in 20 parts of the menstruum employed in its preparation, forming a nearly clear solution. — 2. It should have a uniform texture and color, and be of a proper consistence. — 3. If a narcotic or active extract, it may be exhibited in proper doses, and its effects watched. Its activity may also be tested on any small animal. — 4. An assay for the proximate vegetable principle (alkaloid, etc.) contained in the plant from which it has been prepared may be made. The extracts prepared from the expressed juices of plants, without straining off the coagulated albumen, are, of course, exceptions to the first test. Unfortunately, these tests are not always easily performed, and the last two are inapplicable to those extracts that exercise no very marked physiological action, unless when taken in repeated doses, long continued. This want of a ready means of accurately testing the qualities of extracts has enabled the fraudulent manufacturer to sell inferior articles with impunity, and often without the least fear or danger of detection.

**Extrait** [Fr.], literally, an extract. Among perfumers, extraits are mostly spirituous solutions of the essential oils or odorous principles of plants and other fragrant substance. The French commonly apply the term to any concentrated spirit, either simple or compound. In French perfumery upwards of 60 preparations of the kind are distinguished by this name. The extracts of *jasmine*, *jouquil*, *May-lily*, *orange-blossoms*, *violets*, and other like flowers of delicate perfume are obtained by agitating and digesting the "huiles" and "pomades" of the flowers with the purest rectified spirit in the manner described under SCENTED SPIRITS ("esprits"). This process is repeated with fresh oil or pomade until the spirit is rendered sufficiently fragrant. The other extracts (both simple and compound) are made by the common methods of infusion and distillation. See ESSENCE, EXTRACT, SPIRIT, etc.

**Extra State**, a grade of flour made of spring wheat bolted clear.

**Extravagance**, recklessness and improvidence; a waste of materials.

**Eye (Artificial)**, a shell or segment of a

hollow sphere, usually made of enamel, and so inserted as to present the appearance of the natural eye.

**Eye-Blinds**, bandages for a horse's eyes when being singed, bled, etc.

**Eye-Bolt**, a small ring-bolt used on shipboard, to which ropes are fastened.

**Eyebright**, a meadow plant, the *Euphrasia officinalis*, used medicinally.

**Eye-Flap**, a blinder on a horse's headstall.

**Eye-Glass**, a single spectacle-glass worn by near-sighted persons; the outer glass of a telescope, which is placed against the eye.

**Eyelet**, a short metallic tube whose ends are flanged over against the surfaces of the object in which the said tube is inserted. It is used as a bushing or reinforce for holes, to prevent the tearing of the perforated edge of the fabric or material by the lacing. Eyelets are made from strips of metal by a cutting and punching operation, or punching and shaping. — *E. H. Knight*.

**Eye-Piece**, the lens or combination of lenses used in microscopes or telescopes to examine the aerial image formed at the focus of the object-glass.

## F

**Fabric**, the texture or structure of a manufactured article. — Cloth of any description or of any material made by weaving or felting. — The frame or structure of anything.

**Fabricant** [Fr.], a manufacturer.

**Face**, the edge, surface, or front of anything. — The dial of a watch.

**Face-Guard**, a wire-gauze mask, with windows for the eyes, used by workmen, as in stone-breaking, in chemical or manufacturing purposes, etc.

**Facets**, the various sides into which a precious stone, etc., is cut, and which contribute much to its reflective brilliancy.

**Face-Wheel**, **Crown-Wheel**, **Contrate-Wheel**, is a wheel in which the cogs are perpendicular to the plane of motion.

**Fac-simile**, a true likeness or representation of anything; an exact copy of a handwriting.

**Factitious**, made by art, in distinction from what is produced by nature; artificial.

**Factor**, a commercial agent residing at a distance from his principal, and having the superintendence of some branch of his employer's trade in the place where he acts. A factor differs from an ordinary agent in this, that he does not represent his principal, but acts as a principal himself in his transactions with third parties. He is distinguished from a broker, in as far as he has the personal possession and management of the goods over which his superintendence extends. The factor carries on his commercial operations on commission. He receives consignments from his principal, and makes sales and remittances in return, balancing accounts from time to time. He may act without disclosing the name of his principal. He frequently holds a *del credere* commission (see *DEL CREDERE*). Like other mandatories, the factor is personally responsible for whatever he may do exceeding the powers delegated to him, and, where they are not expressed in the terms of his commission, his powers will be limited by the custom of the trade. He is not responsible "at all events" (as it is termed) for the safety of goods within his charge, that is to say, he is not liable for them as if he had insured them against all risks; but he ought to bestow on them the same care as on his own property, and it would appear that he will be amenable to his employer if he do not. He is not in the general case responsible for the consequences of fire, robbery, or other accident; but there are precautions which, in certain circumstances, he must adopt. One of the most important is that of protecting his principal's interest by insurance, and, if he have effects in hand, he is in all cases bound to comply with directions to insure, being, on failure, himself considered responsible. Where goods are consigned to a factor, his title to them, and right to dispose of them, is generally conveyed in an indorsed bill of lading; but in questions with parties privy to the transaction, it is held that a letter of advice is sufficient. Where the factor has absolute power to sell, indorsement of a bill of lading while the goods are at sea will pass them absolutely, and bar the principal's right to stop *in transitu*; and in the absence of fraud it seems that the assignee's knowledge of the factor's character would not affect his title; for, in order to make notice material, it must be notice of something inconsistent with the right of the assigner to do the act under which the assignee claims, or of such circum-

stances as render the bill of lading not fairly and honestly assignable. But, inasmuch as the character of a factor is consistent with the power to sell, the knowledge of this circumstance would not probably be considered as any impeachment of the transaction if it would be otherwise valid. A factor has a lien on the goods consigned to him, not only for charges affecting those goods, but for his general balance. The lien extends to every portion of the goods, and, when they are disposed of, to the proceeds. On parting with possession, the factor abandons the lien; and goods transmitted to him with a specific appropriation are excepted from it.

**Factorage**, the commission paid to a factor by his employer for business done.

**Factory**, a word more commonly used in England than in this country as an abbreviation for manufactory, etc.; usually applied to buildings of an extensive scale, where complicated machinery, worked by motive-power, is used. In the U. States, any building in which textile products are manufactured by machinery worked by steam, water, or some other power, is called a mill.

**Factory-Maund**, a commercial weight of India, of 74 lbs. 10 oz. 10½ drachms, avoirdupois, and less ponderous than the ordinary bazaar maund.

**Factotum**, a useful person; one who can turn his hand readily to anything.

**Facture** [Fr.], **Fattura** [It.], **Factura** [Port. and Sp.], an invoice or bill of parcels; a written account of the particulars of merchandise shipped or sent to a purchaser.

**Faculty**, a privilege or dispensation. — A body of masters or professors of law, medicine, sciences, etc.

**Fade**, to wear away; to wither or lose color or distinctness, as in silks, colored stuffs, etc.

**Fadge**, a name amongst leather-sellers for a covering of undressed leather.

**Fading**, loss of strength or color; decay.

**Fag**, one who works hard. — A knot in cloth.

**Fag-End**, the refuse part or worst end of a web of cloth or any fabric. — The untwisted end of a rope.

**Fagot**, a quantity of steel in bars, equal to 120 lbs.; a bundle of sticks of wood about 3 feet long and 2 feet round.

**Fagotto**, a brass wind-instrument resembling a bassoon.

**Faham-Tea**, a name given in the Mauritius to the dried leaves of the *Epimedium macranthum* (Fig. 169), a fragrant herbaceous plant, which owes its odor to the presence of coumarin. The infusion is drunk to promote digestion, and is useful for certain diseases of the lungs.

**Fahrenheit**, a thermometer scale in which the freezing-point of water is fixed at 32 degrees, and the boiling-point at 212. See *THERMOMETER*.

**Faience**, or **Fayence**. See *POTTERY*.

**Fail**, to suspend payment; to become insolvent or bankrupt.

**Failure**. See *INSOLVENCY*.

**Faints**, or **Feints**, the inipure spirit in the process of distillation passing over at first and at last from the still; the former being called strong and the latter weak faints.

**Fair**. A *F.* is defined as a "greater species of market recurring at more distant intervals"; both have been distinguished by Lord Coke from

"mart," which he considers as a greater species of *F.*; all three may comprehensively be described as customary or legalized public places for the sale of commodities (including labor). Thus, in England, no *F.* can be held without a grant from the sovereign, or prescription which presupposes such grant. In France the establishment and abolition of *F.* — with the exception of the cattle-markets and the markets of the metropolis — are generally left to the discretion of the departmental prefects. The most commonly accepted derivation of the word *F.* is from *feriae*, a name which the church borrowed from Roman custom and applied to her own festivals. A *F.* was generally held during the period of a saint's feast, and in the precincts of his church or abbey, — the time and the place of the chief popular assemblage. Most of the famous *F.* of mediæval

FIG. 129. — FAHAM-TEA PLANT.

Europe, with their tolls or other revenues, and, within certain limits of time and place, their monopoly of trade, were grants from the sovereign to abbots, bishops, and other ecclesiastical dignitaries. Their "holy day" associations are preserved in the German word for *F.*, *Messen*. There are grounds, however, for the supposition that *F.* were already existing national institutions long before the church turned, or was privileged to turn, them to her own profit. The Romans appear to have elaborated a market-law similar to that in force throughout mediæval Europe. It has also been supposed that the ancient *F.* of Lyons were a special privilege granted by the Roman conquerors; and Sidonius Apollinaris, A. D. 427, alludes to the *F.* of the district afterwards known as the county of Champagne, as if they were then familiarly known institutions. *F.*, in a word, would not only have arisen naturally, wherever the means of communication between individual cen-

tres of production and consumption were felt to be inadequate to the demand for an interchange of commodities; but, from their very nature, they might be expected to show some essential resemblances, even in points of legislation, and where no international transmission of custom could have been possible. Thus, the *F.* courts of pre-Spanish Mexico corresponded very closely to those under whose supervision the *Beaucaire F.* is conducted in the present day, and the Spaniards, when first they saw the Mexican *F.*, were reminded of the like institutions in Salamanca and Granada. But, notwithstanding the great antiquity of *F.*, their charters are comparatively modern, — the oldest known being that of St. Denys, Paris, which Dagobert, king of the Franks, granted (642 A. D.) to the monks of the place "for the glory of God, and the honor of St. Denys at his festival." The first recorded grant in England appears to be that of William the Conqueror to the Bishop of Winchester, for leave to hold an annual "free *F.*" at St. Giles's Hill. The monk, who had been the king's jester, received his charter of Bartholomew *F.*, Smithfield, in the year 1133. And in 1248 Henry III. granted a like privilege to the Abbot of Westminster, in honor of the "translation" of Edward the Confessor. Sometimes *F.* were granted to towns as a means for enabling them to recover from the effects of war and other disasters. Thus, Edward III. granted a "free *F.*" to the town of Burnley in Rutland, just as, in subsequent times, Charles VII. favored Bordeaux, after the English wars, and Louis XIV. gave *F.* charters to the towns of Dieppe and Toulon. The importance attached to these old *F.* may be understood from the inducements which, in the 14th century, Charles IV. held out to traders visiting the great *F.* of Frankfort-on-the-Main. The charter declared that both during the continuance of the *F.* and for eighteen days before and after it, merchants would be exempt from imperial taxation, from arrest for debt or civil process of any sort, except such as might arise from the transactions of the market itself and within its precincts. Philip of Valois's regulations for the *F.* of Troyes in Champagne might not only be accepted as a fair type of all subsequent *F.* legislation of the kingdom, but even of the English and German laws on the subject. The *F.* had its staff of notaries for the attestation of bargains, its court of justice, its police officers, its sergeants for the execution of the market judges' decrees, and its visitors, — of whom we may mention the *prud' hommes*, — whose duty it was to examine the quality of goods exposed for sale, and to confiscate those found unfit for consumption. The confiscation required the consent of five or six representatives of the merchant community at the *F.* The effect of these great "free *F.*" of Europe on the development of society was indeed great. They helped to familiarize the western and northern countries with the banking and financial systems of the Lombards and Florentines, who resorted to them under the protection of the sovereign's "firm peace" and the ghostly terrors of the Pope. They usually became the seat of foreign agencies. Like the church on the religious side, the free *F.* on the commercial side evoked and cherished the international spirit. And during long ages, when commercial "protection" was regarded as indispensable to a nation's wealth, and the merchant was compelled to "fight his way through a wilderness of taxes," they were the sole and, so far as they went, the complete substitute for our modern free trade. Their privi-

leges however, were, from their very nature, destined to grow more oppressive and intolerable the more the towns were multiplied and the means of communication increased. The people of London were compelled to close their shops during the days when the Abbot of Westminster's *F.* was open. But a more curious and complete instance of such an ecclesiastical monopoly was that of the St. Giles's *F.*, at first granted for the customary three days, which were increased by Henry III. to sixteen. The Bishop of Winchester was, as we have seen, the lord of this *F.* On the eve of St. Giles's feast the magistrates of Winchester surrendered the keys of the city-gates to the bishop, who then appointed his own mayor, bailiff, and coroner, to hold office until the close of the *F.* During the same period Winchester and Southampton also—though it was then a thriving trading town—were forbidden to transact their ordinary commercial business, except within the bishop's *F.*, or with his special permission. The bishop's officers were posted along the highways, with power to forfeit to his lordship all goods bought and sold within seven miles of the *F.*,—in whose centre stood "the pavilion," or bishop's court. It is clear, from the curious record of the "Establishment and Expenses of the Household of Percy," fifth earl of Northumberland, that *F.* were the chief centres of country traffic even as late as the 16th century. They began to decline rapidly after 1759, when good roads had been constructed and canal communication established between Liverpool and the towns of Yorkshire, Cheshire, and Lancashire. In the great towns their extinction was hastened in consequence of their evil effects on public morals. All the London *F.* were abolished as public nuisances before 1855,—the last year of the ever-famous *F.* of St. Bartholomew; and the *F.* of Paris were swept away in the storm of the Revolution.

*English Fairs and Markets.*—For the general reasons apparent from the preceding sketch, *F.* in England, as in France and Germany, have very largely given way to markets for specialties. Even the live-stock market of the metropolis is being superseded by the dead-meat market, a change which has been encouraged by recent legislation on cattle disease, the movements of home stock, and the importation of foreign animals. Agricultural markets are also disappearing before the "agencies" and the corn exchanges in the principal towns. Still there are some considerable *F.* yet remaining. Of the English *F.* for live-stock, those of Weyhill in Hampshire (Oct. 10), St. Faith's, near Norwich (Oct. 17), as also several held at Devizes, Wiltshire, are among the largest in the kingdom. The first named stands next to none for its display of sheep; while the second is the principal resort of the Scotch drovers and cattle-dealers, and supplies a large proportion of the fat stock required for the London market. Horncastle, Lincolnshire, is the largest horse *F.* in the kingdom, and is regularly visited by American and Continental dealers. The other leading horse *F.* in England are Howden in Yorkshire (well known for its hunters) and Woolbridge (on Lady Day) for Suffolk horses. Exeter December *F.* has a large display of cattle, horses, and most kinds of commodities. Large numbers of Scotch cattle are also brought to the *F.* of Market Harborough, Carlisle, and Ormskirk. Ipswich has a *F.* for lambs on the 1st of August, and for butter and cheese on the 1st of September. Gloucester *F.* is also famous for the last-named commodity. The guild or jubilee held at Preston,

Lancashire, every twentieth year, occurred last in 1862. Falkirk *F.*, or tryst, for cattle and sheep, is one of the largest in Scotland; and Ballinasloe, Galway, holds a like position among Irish *F.* The Ballinasloe cattle are usually fed for a year in Leinster before they are considered fit for the Dublin or Liverpool markets. In 1790 there were 61,931 sheep and 8,632 horned cattle exhibited at the *F.*, and for 1867 the returns, in the foregoing order, were 73,364 and 23,734.

*French Fairs.*—The most important is that of Beaucaire, once among the first in Europe. Its position on the Rhone (14 miles east of Nismes), and its connection with the canals, still enable it to maintain a high rank among the Continental markets. It lasts from the 22d to the 28th July, and is visited by about 60,000 persons, from all parts of the Continent between Spain and the Levant; articles of all descriptions are sold at it. It is a rule that all bills due at this *F.* must be presented on the 27th and protested, if necessary, on the 28th.

*German Fairs.*—First, though no longer of world-wide importance, are those of Frankfort-on-the-Main, Frankfort-on-the-Oder, and Leipsic. Those of Frankfort-on-the-Main begin on Easter Tuesday and on the nearest Monday to Sept. 8, respectively, and their legal duration is three weeks, though the limit is regularly extended. The *F.* of the second-named city are *Reminiscere*, February or March; *St. Margaret*, July; *St. Martin*, November. Ordinarily they last fifteen days, which is double the legal term. The greatest of the German *F.* are those of Leipsic, whose display of books is famous all over the world. Its three *F.* are dated Jan. 1, Easter, Michaelmas. The Easter one is the book *F.* which is attended by all the principal booksellers of Germany, and by many more from the adjoining countries. Most German publishers have agents at Leipsic. As many as 5,000 new publications have been entered in a single Leipsic catalogue. As in the other instances given, the Leipsic *F.* last for three weeks, or nearly thrice their allotted duration. Here no days of grace are allowed, and the holder of a bill must demand payment when due, and protest, if necessary, on the same day, otherwise he cannot proceed against either drawer or endorser.

*Russian Fairs.*—These are very numerous, the chief being those of Nijni Novgorod, of Irbit in Perm, Kharkoff (January and August), Poltava (August and February), Koreunais in Koursk, Ourloupinskia in the Don Cossack country, Krolevetz in Tchernigoff, and a third *F.*, held at Poltava on the feast of the Ascension. It is calculated that in 1851 the aggregate value of goods sold at the above-named *F.* amounted to nearly 120,000,000 silver roubles. The chief *F.* of Novgorod is attended by 100,000 to 130,000 persons from all parts of Asia and of Eastern Europe. Thirty years ago the *F.* of Kiatcha, on the Russo-Chinese frontier, yielded one million sterling in revenue; but in 1867 the sum had fallen by one half. This was in consequence of the opening of new communications, and the abolition of the Kiatcha monopoly.

*Turkish Fairs.*—Of these there are a very considerable number, and the vast bulk of the internal commerce of the country is transacted at them. Among the most noteworthy are the *F.* of Usundji, in Roumelia, on a tributary of the Moritza, 40 miles from Adrianople; Janina in Albania; Strouga, on the lake of Orida; Novi-Bazaar in Upper Mœsia; Islioni in Thrace; Nicopoli and Prelip in Macedonia; Eski-djouma in Bulgaria;

and Zeitoun and Pharsalia in Thessaly. There is a large show of western manufactures at the Usundji *F.*

**Indian Fairs.**—The largest of these, and perhaps the largest in Asia, is that of Hurdwar, on the upper course of the Ganges. The visitors to this holy *F.* number from 200,000 to 300,000; but every twelfth year there occurs a special pilgrimage to the sacred river, when the numbers may amount to a million or upwards. Those who go solely for purposes of trade are Nepalese, Mongolians, Thibetans, Central Asiatics, and Mahomedan peddlers from the Punjab, Scinde, and the border states. Persian shawls and carpets, Indian silks, Cashmere shawls, cottons (Indian and English), preserved fruits, spices, drugs, etc., together with immense numbers of cattle, horses, sheep, and camels, are brought to this famous *F.*

**American Fairs.**—In the U. States the word "fair" is principally confined to assemblages for the sale and purchase, under the control of private companies, and for charitable purposes, of fancy articles, which are generally contributed gratuitously. The word "fair" is also applied to state and county agricultural and industrial exhibitions, intended for competition rather than general traffic. Among the best known of these was the "New York World's Fair," opened in 1853. The American Institute of New York, the Franklin Institute of Philadelphia, the Mechanics' Institute of Boston, and other institutions of similar character, hold annual *F.* for the encouragement of the agricultural and manufacturing arts.

**Fairfield.** See CONNECTICUT.

**Fairfield,** a fire insurance Co., located in South Norwalk, Conn., organized in 1869. *Statement:* Jan. 1, 1879, cap. stock paid up in cash, \$200,000; net surplus, \$23,400.51; total cap. and surplus, \$233,400.51; risks in force, \$11,290,538; premiums, \$125,830.13; premiums received since the organization of the Co., \$1,130,778.07; losses paid, \$664,354.05; cash dividends paid to stockholders, \$140,000.

**Fairing,** a gift or present purchased at a fair.

**Fairly,** justly; equitably; plainly; candidly.

**Fairway,** the mid passage in a short channel; the navigable part of a river.

**Falcated,** bending like a hook.

**Falding,** a kind of coarse cloth.

**Falerian Wine.** See ITALIAN WINES.

**Falkland Islands** [*Fr. Malvinas; Sp. Malvinas*], a group of islands belonging to Great Britain. They are the only considerable cluster in the South Atlantic Ocean, and lie about 300 m. E. of the Straits of Magellan, between lat. 51° 15' and 52° 30' S., lon. 57° 40' and 61° 20' W. They consist of East *F.* (area 2,700 sq. m.), West *F.* (2,000 sq. m.), and upwards of 100 small islands (islets, rocks, and sandbanks), comprising in the aggregate 4,740 sq. m., and a population, in 1878, of 1,339, of whom but 384 were females. These islands are of some importance as a commercial and military station.

**Fall,** a decrease in price or value. — Autumn; the season of the fall of the leaf. — A border of lace to the neck part or body of a lady's evening dress. — A short veil for a lady's bonnet or hat. — The amount of descent in a given distance; the vertical pitch of water at a mill; the inclination of a water-course. — The loose end of a tackle; that part to which the power is applied in hoisting.

**Fall-Board,** the wooden drop shutter of a window, which moves up and down on hinges.

**Fall Goods,** goods adapted for the demands of the fall or autumnal season.

**Falling Market,** a continuous decline in the price of goods.

**Fallow,** untilled land; ground lying at rest, not under a grain crop.

**Fall River,** a city and port of entry of the State of Massachusetts, 46 m. S. of Boston, situated on the Fall River, at its junction with the Taunton, which falls into Mount Hope Bay, a branch of Narragansett Bay. The harbor on Taunton River is safe and easy of access, and has depth of water sufficient for the largest ships. Fall River has a large coasting-trade, and is engaged in the whale and other fisheries. It has extensive cotton and woollen factories, bleaching-works, foundries, etc., and communicates regularly with New York by steamers, and with Boston by railway. Pop. 30,000.

**Falmouth.** See GREAT BRITAIN.

**False-Core,** a name among brass-founders for a loose piece of the mould not intended for holes; by the iron-founder it is called a drawback.

**False-Keel,** pieces of timber secured under the main keel of vessels.

**False-Key,** a pick-lock.

**False Pretences,** false representations and statements made with a fraudulent design to obtain "money, goods, wares, or merchandise," with intent to cheat. But misrepresentations may be made for the purpose of gaining credit, without intention to cheat. Instances have occurred where goods so obtained, after having been profitably disposed of by the party obtaining them, were paid for according to the terms. It seems, however, that in the construction of law the crime is the same. The intent to cheat is inferred from the misrepresentation, and the intent is all that is requisite. It is not necessary that the party defrauded should sustain loss. Property acquired by means of false pretences may be recovered by the party from whom it was thus obtained; and obtaining goods by false pretences is an indictable offence. — *T. McElrath.*

**Famine,** dearth or destitution; a scarcity of food or provisions for sustenance.

**Famis,** a kind of Spanish gold cloth or brocade.

**Fan,** a well-known hand ornament or instrument chiefly used by ladies to cool themselves by agitating the air. Upward of 3,000 years ago the artists of ancient Egypt painted the fan on the walls of the tombs at Thebes, where the Pharaoh sits surrounded by his fan-bearers. The fan is mentioned by Euripides, and its Grecian forms were far more beautiful than the Egyptian. The wings of a bird joined laterally and attached to a slender handle formed the simple yet graceful fan of the priest of Isis, when Isis became a Grecian deity. It was sometimes formed of feathers of different lengths, spread out in the form of a semi-circle, but pointed at the top. This fan, the precise type of the state-fan of India and China of the present day, was waved by a female slave. When the Romans were at meals, it was the duty of certain slaves, when the weather was warm, to cool the room with fans and drive away the flies. The modern Greek church places a fan in the hands of its deacons to guard the officiating priest and the elements from desecration. When the fan was brought to France by Catherine de Medicis, it was so constructed that it could be folded in the manner of those used in the present day. Fans, in the luxurious reigns of Louis XIV. and XV., shone with gilding and gems, and were ornamented with the pictures of Boucher and Watteau.

China and France are the two great fan-manufacturing countries. In the lacquered fans the superiority of the natives of China is fully admit-

ted. These are unrivalled both in lowness of price and in originality of design, brilliancy of coloring, and in general correctness of workmanship. In China the manufacture of fans is almost entirely confined to Canton, Soutchou, Hang-tehoo, and Nankin. The fans of ivory and bone, and of feathers, are made exclusively for exportation to Europe or America. Those used by the Chinese and the Japanese are of bamboo, polished or japanned, and covered with paper. They are largely imported in the U. States, principally from Japan.

**Manuf.** Fan-making calls for a considerable amount of delicacy in the working up of the materials which form them. Ivory, mother-of-pearl, tortoise-shell, bone, wood, gold, silver, silk, satin, parchment, paper, whalebone, lambskin, gauze, feathers, — all are employed, according to the price paid for the fan, which may be as high as \$500, or as low as a half-cent. In France this manuf. has arrived at a high degree of perfection, and presents a remarkable instance of the subdivision of labor. About twenty different operations, performed by as many pairs of hands, are necessary to the production of a fan which sells for less than one cent. The processes are not all carried on in the same manufactory, but form four distinct branches of trade, directed by distinct masters; but the operatives usually work at home at their own houses. The framework of fans is mostly made in the department of Oise, where 2,000 men, women, and children are thus employed. The woods employed are chiefly plum, ebony, lime, and sandal-wood; and the piercings, which form such a general decoration to fans, are performed by minute saws, which the workman makes for himself out of pieces of watch-spring. In one fan there are in some specimens 1,000 saw-piercings in a square inch of mother-of-pearl. The printing, the coloring, the mounting, and the finishing of fans are mostly conducted at Paris, where the fan-factories are on a considerable scale. Fans are also extensively made in England, Germany, and the U. States; but the greatest number of fans used by the world of fashion come from Paris.

**Imp. duty:** common palm-leaf fans, free; all others, including those made of the leaf of the palm-tree, with artificial handles, 35 per cent.

**Ventilating Fan.** When a drum or wheel is rotated, the centrifugal force tends to drive out water or air from near the axis towards the circumference. This has suggested a *ventilating fan* for drawing out impure air from mines and large buildings. Desaguliers invented such a fan many years ago. It was a hollow wheel, 7 feet diameter by 1 foot broad or deep; it was divided into compartments by twelve radial partitions, all opening outwardly into a circular space near the fireplace, and inwardly into a central opening. This wheel revolved nearly in contact with an outer cell. By so doing, air was sucked by the central opening into the twelve channels, along these to the circular space, and thence into an exit-pipe. The partial vacuum thus formed at the centre of the wheel incited a rush of air from the shaft of a mine with which it was placed in combination; and in this way foul air was drawn out of the mine. This wheel was rotated by hand; but the descent of a weight might be made to produce the effect; and so, of course, might water-power and steam-power. All the ventilating fans since invented have acted on a similar centrifugal principle, however modified in detail. Fairbairn and Lillie's fan, much used in the large factories of the North, will produce such a powerful draught as to draw all the vitiated air out of a gallery 200 or 300 feet long; and by connecting pipes, all the rooms in all the successive stories can be similarly ventilated. Or it may be used for drawing all dust and fibres out of the workshops in which cotton and other materials are treated. Or it may draw air out of lofty shafts, or even blow air into forge fires. In one form of construction, the wheel is concentric with the case in which it works; but a greater working efficiency is obtained by making the two eccentric, the wheel being nearer to one side of the case than to the opposite. In Chaplin's *duplex pressure fan* there are two wheels instead of one, but both revolving on one axis; the air is drawn from the one to the other, and thence discharged with greater force than when only one wheel is used

The partitions, vanes, radii, or spokes vary greatly in number and form, according to the mode in which the inventor intends them to act. Other improvements, introduced by many inventors, have so improved the ventilating fan, that it is now rapidly superseding the other blowing-machines, giving a uniform blast of air instead of a series of puffs. The fan represented in Fig. 170 is used as a blowing-machine in manufactories to send air into the furnaces. It must receive an extremely rapid motion, and then discharges air with great

Fig. 170. — VENTILATING FAN.

regularity into the tub with which it communicates. Its arms are slightly curved in a way contrary to that in which it moves, so that they more easily abandon the air with which they are in contact when they pass before the pipe seen at top of the figure, which conveys air to the furnace.

**Fanal** [Fr.], a ship's lantern, or watch-light; a lighthouse.

**Fancy-box Maker**, a manufacturer of cardboard and other boxes, for linen goods, or confectioners' use, etc.

**Fancy-check Muslins**, cambrics marked with cords and stripes, by heavy threads introduced into the warp and weft.

**Fancy-Goods**, fabrics made of various patterns, as ribbons, silks, satins, etc., differing from those which are of a plain or simple color; light and ornamental goods; small wares.

**Fancy Woods**, a name under which most of the furniture woods are sold, such as mahogany, rosewood, satin, kingwood, etc.

**Fanega**, a Spanish measure used for different purposes. As a dry measure in Spain, it varies from  $1\frac{1}{2}$  to  $2\frac{1}{2}$  bushels. In South America, the fanega of Chile, for grain, ranges from 153 lbs. weight to upwards of 200 lbs.; in Central America, the fanega of maize weighs 400 lbs.; in Monte Video, it is as much as  $3\frac{1}{2}$  bushels; but the average computation may be taken at 5 fanegas to the English quarter of 8 bushels. As a land measure the fanega is 40,000 varas of about  $2\frac{1}{2}$  feet each.

**Fanegada**, a Spanish land measure; as much ground as may be sown with a fanega of grain; about 153 square yards, = 170 varas.

**Faneuil Hall Fire Insurance Co.**, located in Boston, Mass., organized in 1871. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$300,000; net surplus, \$28,258.85; risks in force, \$22,440,811; premiums, \$310,697.53; premiums received since the organization of the Co., \$1,319,360.48; losses paid, \$711,747.06; cash dividends paid to stockholders, \$50,250.

**Fang**, a projecting tooth or prong in a lock, bolt, or tumbler. — A long nail. — The tang of a

tool. — On shipboard, the valve of a pump-box; also the bend of a rope.

**Fangot**, a quantity of wares, as raw silk, etc., from 1 to 2½ cwt.

**Fank**, the name, in some parts of Scotland, for a sheep-cot or pen; to coil a rope.

**Fanlight**, a framed window shaped like an out-spread fan, usually placed over doors.

**Fanner**, and **Fanning-Mill**. See **WINNOWING-MACHINE**.

**Fantail**, a kind of joint. — A gas-burner, in which the burning jet has an arched form.

**Fard**, a cosmetic or paint for the face. See **ROUGE**.

**Fardage** [Fr.], the tonnage of a ship.

**Fardel**, a bundle or little pack; a term used in reckoning in Germany, equal to 45 barchets or pieces of cloth of 22 or 24 ells each; the fourth part of a yard of land.

**Fare**, a word of wide application; food or provisions for the table; the price of passage for travelling; the sum paid or due for conveying a person by land or water.

**Farina**, the flour or meal of any species of corn, pulse, tuber, or starchy root. The most important kinds of farina are noticed under their respective heads.

**Farinaceous**, containing meal.

**Farm**, to take or hire at a certain rate per cent; a monopoly, license, or permission to vend certain articles subject to duty; a portion of land with suitable buildings, etc., devoted to agricultural operations.

**Farmer**, a tenant; a lessee; a person employed in the cultivation of land, breeding and rearing live-stock, and the management of the commercial products they yield.

**Farmers' Fire Insurance Co.**, located in York, Pa., organized 1853. *Statement*, Jan. 1, 1879: Net surplus, \$148,208.82; risks in force, \$39,149,523; premiums, \$480,454.27; premiums received since the organization of the Co., \$3,134,554.49; losses paid, \$1,931,280.79.

**Farm-yard Manure**, the excrements of cattle, and other fertilizing substances collected from stables, cattle-sheds, etc., for spreading on land, and largely used.

**Faroe Islands**. See **DENMARK**.

**Farragut Fire Insurance Co.**, located in New York City, organized in 1872. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$200,000; net surplus, \$161,007.78; risks in force, \$24,955,185; premiums, \$123,714.64; premiums received since the organization of the Co., \$947,842.92; losses paid, \$285,463.10; cash dividends paid to stockholders, \$162,000.

**Farrier**, one who shoes horses; one who professes to cure the diseases of horses and cattle; a veterinary surgeon.

**Farthing**, a small English copper coin, the fourth part of a penny, or about one half a cent.

**Fascet**, a rod thrust into the mouth of a bottle, in the operation of glass-blowing, to convey the article to the annealing furnace.

**Fashion** [Fr. *mode*], a term used to signify the prevailing mode or taste in any country, the only recognized quality which it possesses being mutability. It may safely be averred that, in proportion to the influence which fashion exercises in any country may its claim to civilization be vindicated, — nothing being so characteristic of a rude and barbarous state of existence as a rigid adherence to the customs of antiquity. The term *fashion* has generally been considered as applicable chiefly to the adornment of the person, in con-

formity with the prevailing taste as introduced by some individual of consideration in society; but it has a much wider signification, being applied to the most trivial kind of conventional usages, a disregard or ignorance of which is sufficient, in the eyes of the votaries of this tyrannical goddess, to banish the offender beyond the pale of civilized society.

**Fashioner**, one who fashions or shapes things; a tailor.

**Fashioning-Needle**, one of the pins or fingers employed in the knitting-machine to take loops from certain of the bearded needles and transfer them to others for widening or narrowing the work.

**Fass**, a measure of capacity used in Germany, of a very variable character, ranging as a dry measure from 1½ gallons in Dusseldorf, to 11½ in Altona. For charcoal it is 59 gallons at Treves, in Prussia. As a liquid measure it is equally variable and difficult to define, and differs with the nature of the contents. In Vienna the *fass* of wine is about 127½ gallons, in Leipsic it is 83½, and so on. One Hamburg *last* of 60 *fass* is equivalent to 11 imperial quarters; 1 *fass* = 2 *himpten*.

**Fast**, the rope by which a vessel is secured to a wharf; in nautical language, attached to; as when a boat is secured by a rope. A vessel aground is said to be "hard and fast."

**Fast Colors** are colors that produce a fixed and permanent dyeing; that is to say, which do not fade by exposure to the air or by washing.

**Fastening**, a stop or holdfast; a bolt or bar; a screw or spring-catch for window-sashes; also, a security for doors.

**Fathom**, an English nautical measure of 6 feet, chiefly used for measuring the length of cordage, and the depth of water and mines.

**Fat** [Lat. *adeps*], the fat of animals is a concrete oil contained in the cellular membrane of their bodies, more especially round the kidneys, in the folds of the omentum, at the base of the heart, upon the surface of the intestines, and among many of the muscles. Fat varies in consistence, color, and odor, with the animal from which it is obtained. That of the carnivora is usually soft and rank-flavored; that of the ruminantia solid and nearly scentless. It is generally whitest and most copious in the well-fed young animal, and yellowish and more scanty in the old. That under the skin and surrounding the kidneys (*suet*) is also more solid than that in the neighborhood of the movable viscera. In the cetacea, or whale tribe, the fatty secretion assumes the form of oil. These variations in consistency depend upon the relative proportions of solid stearin and liquid olein present in the fat. — The vegetable fats are found in various parts of certain plants, but are generally most abundant in the seeds. They are extracted by simple pressure, or else by boiling. Two kinds of vegetable fat, namely, palm-oil and cocoa-nut oil, are extensively employed in the useful arts. — All fats are lighter than water. They are all soluble in ether, benzole, and turpentine, and may be mixed with each other in any proportion. — In former times, the fats of many animals were employed in pharmacy, but at present those principally used are lard and suet. In perfumery, in addition to these, beef marrow and bear's grease are employed. For both these purposes the crude material is cut into small pieces, and freed as much as possible from all extraneous membranes; after which it is placed in a boiler with water, and heated until it is completely fused, when the whole is strained, and allowed to cool very slowly. By

this means a cake of cleansed fat is obtained, which may be readily separated from any adhering water.—Fats and the fat-oils are best preserved by being run into glazed jars, and secluded from the action of the air. A little benzoic acid or gum-benzoin, dissolved in them by heat, will generally prevent, and in all cases greatly defer, the accession of rancidity. Nitric ether and its alcoholic solution act in the same manner. A few drops are not only sufficient to prevent rancidity, but will even destroy the disagreeable odor of rancid fat. When heated to remove the alcohol, they immediately become bright, clear, and scentless.

**Fat-Lute**, a mixture of pipe-clay and linseed-oil for filling joints.

**Faucet**, a spout with a peg or spigot for drawing liquor from a cask.

**Fault**, in geology, a fracture of strata accompanied by displacement. See Fig. 85.

**Fauteuil**, a large elbow-chair.

**Favor**, a bunch or knot of ribbons worn at weddings or other festive occasions.

**Fayal Wine**. See AZORES.

**Faying**, in maritime phraseology, the union of two pieces so close that no intervening space occurs.

**Fearnought**, a thick shaggy woollen stuff, used in England for draymen's coats, sailors' pea-jackets, etc. It is also known as dreadnought.

**Feast**, a sumptuous repast; a public banquet or entertainment.

**Feather** [Fr. *plume*; Ger. *Feder*; It. *piuma*; Sp. *pluma*], the light portion of the wings and plumage of birds. The kinds

Fig. 171. — WHITE STORK.

most used for dress and military purposes are those of the ostrich, marabou, stork (Fig. 171), American or three-toed ostrich, emu, heron, birds-of-paradise, ibis, and domestic fowls. The tail-*F.* of the domestic cock, either dyed or in their natural colors, are much used for military plumes. Grebe and loon skins, and swan's down, are also used for muffs and trimmings of ladies' dresses. The most common, and

the largest trade in *F.*, are those from the breast of geese, used for bedding, pillows, etc.

*Imp. duty*: *F.* and downs for bedding, free; ostrich, vulture, cock, and other ornamental crude *F.*, 25 per cent; the same, dressed, colored, or manufactured, 50 per cent; artificial and ornamental *F.*, or parts thereof, of whatever material composed, and not otherwise provided for, 50 per cent.

**Ornamental F.** The *F.*-worker, or *plumassier*, makes up *F.* into ornamental adornments, chiefly for head-dresses. Ostrich *F.* are those most prized, principally the purely white drooping plumes from the back and near the tail of the male bird. *F.* are prepared for ornamental purposes by scouring them with white soap-and-water (1 oz. to the pint), used hot: they are next well rinsed in several successive portions of pure water, and, after being drained and shaken, are, lastly, passed through water slightly blued with pure indigo, and dried out of the dust. When dry, the ribs are generally rubbed with a piece of glass having a curved notch in it, for the purpose of increasing their pliancy, and the filaments are curled by drawing them between the edge of a blunt knife and the ball of the thumb of the hand which holds it. Black, brown, or gray *F.* can now be bleached sufficiently to enable them to be

dyed any required color. The process is as follows: The *F.* are first thoroughly washed with soap-and-water, to free them from any oil they may contain. They are next transferred to a bath composed of bichromate of potash dissolved in water, to which has been added a few drops of nitric or sulphuric acid. In this bath they rapidly lose their black, brown, or gray color, and become almost white. On being removed from this bath they are well rinsed in water, and are then fit to be dyed, even the most delicate color. Great care is required in the process, as the flue of the *F.* is apt to be destroyed, if kept too long in the bath. A bleached *F.* may be readily known by the yellow color of its stem. Other methods have been adopted, such as a bath of chloride of lime, peroxide of hydrogen, or sulphurous acid, etc., but the bichromate bath gives the best results.—*F.* are dyed rose-color by safflower and lemon-juice; red by Brazil-wood, followed by cudbear; blue by indigo; yellow by turmeric; alum being the usual mordant. Aniline colors, however, are fast superseding the others for superior work.

**F. Beds**. The best *F.* for this purpose are those of the goose, being more soft, elastic, and warm than others. The *F.* are said to be better if taken from the living than the dead bird; and this leads in some parts of England to the selection of regular seasons for *F.*-plucking. Poultry *F.*, such as those of the turkey, duck, and fowl, are used for cheaper beds and pillows. The preparation of the *F.* for the bed-stuffers involves processes of steeping in lime-water, draining, washing in clean water, drying upon nets, steaming, beating, etc. For the fine down of some birds (a kind of incipient *F.*) see EIDER DOWN. This beautiful substance ought not to be lain upon, as it thereby loses its elasticity; it is properly used only in stuffing quilts. See QUILL PENS.

**Feather-Duster**, a light brush made of feathers.

**Feather-Edged**, planks, or any rough substance, in which one side is much thinner than the other.

**Feather-Flowers**, artificial flowers made of feathers, which are used by ladies for head ornaments, and for fancy plumes and groups for rooms.

**Fecamp**. See FRANCE.

**Fecula**, the matter which subsides from cold water in which bruised or rasped vegetable substances have been washed. The *F.* obtained from the seeds of the cereals and leguminosæ, and from tuberous or bulbous roots, consists of nearly pure starch. In some cases the starch is associated with the green coloring matter (*chlorophyll*) and the narcotic principles of the vegetables which yield it. The green *F.* obtained by straining the expressed juices of the leaves and herbaceous parts of plants is of this character. The *F.* of all the amylaceous roots, rhizomes, and tubers, may be easily obtained, on the small scale, by rasping them, pressing, and working the pulp in cold water, and after straining the resulting milky liquid through a hair sieve, allowing it to settle. The sediment may be again washed by diffusion through clean cold water, and must be, lastly, collected, and dried out of the dust, and without artificial heat. The *F.* of narcotic plants for medicinal purposes is obtained by allowing the expressed juice to repose for 24 hours, and then decanting the clear portion, and drying the residue. Sometimes heat is employed. See ARROW-ROOT, STARCH, etc.

**Fedelini**, a kind of dried Italian paste in a pipe form, of a smaller size than vermicelli.

**Fee**, a gratuity or reward given to a professional man, as a physician or lawyer, for advice or service; a perquisite claimed by official personages under legal authority, or by prescription.

**Feed**, food for beasts, especially for horses and cattle; as oats, hay, corn, ground meals, etc.—The supply of material to a machine.—The motion or action which carries stuff forward to a machine.

**Feed-Bag**, a nose-bag for a horse, to contain his noonday feed.

**Feeder**, the stream supplying a river or canal.—A branch railroad running into the main-trunk

line. — A large head or supply of fluid iron to a runner or mould in heavy castings. — An auxiliary or a supplying part of a machine, that which leads along the stuff being operated upon.

**Feed-Hand,** a rod by which intermittent rotation is imparted to a ratchet-wheel.

**Feeding-Bottle,** a glass or india-rubber bottle for supplying milk or other liquid nutriment to an infant in the absence or indisposition of its mother.

In the artificial rearing of infants it is of importance that food should be given to them from a *F. B.* By this means the natural method of taking nourishment is imitated, the muscles of the mouth and cheeks are brought into play, and the secretion of saliva is encouraged and increased. Almost all babies will take their food more readily by this method, their instinct teaching them to suck everything that is put into their mouths. To be satisfactory, a *F. B.* must fulfil three indispensable conditions: it must be simple in construction and easily manageable; it must be capable of being readily cleaned; and in its use the milk must flow easily and without great effort on the part of the infant. The ordinary feeder in use at the present time consists of a flattened glass or india-rubber flask, closed at the mouth by a cap, which fits over the neck. An india-rubber tube passes through the cap, and is connected inside the bottle with a straight glass pipe. The other end of the elastic tube is attached to the teat, or mouth-piece, by means of a short hollow cylinder called the "union-joint," and the teat is firmly fixed to this by means of the shield. In this apparatus it is important that the channel through the tubes should be perfectly free. The point at which the channel is narrowest is the union-joint, which connects the mouthpiece with the flexible tube. In a badly made bottle an impediment may exist at this point from carelessness in the manufacture, and may present a great obstacle to the ready passage of the fluid. Care also should be taken that the flexible tube passes completely through the cap, before it becomes connected with the glass pipe. This is very important, because, the glass tube being thus free to move, its end is able to sink to whichever side of the bottle is undermost, and therefore always remains below the level of the fluid. The method of connection of the cap with the neck of the bottle is not unimportant. It should not be too tight, or air will be prevented from entering the bottle to supply the place of the milk which is withdrawn. With badly made bottles, infants often have great difficulty in drawing up the milk, and can only do so by violent efforts, which soon exhaust their strength or their patience. There are two reasons why milk in these cases may not flow easily, — either the cap fits too tightly, so that air cannot enter with sufficient facility in proportion as the liquid contents become diminished, or the india-rubber forming the flexible tube is too thin, so that it collapses when suction is applied. In the first case, a small hole should be made through the cap, so as to allow a free admission of air, or if the bottle be closed at the mouth by a perforated cork, this may be slightly eased at the neck of the bottle, so as to fit less closely. In the second case, stouter india-rubber should be used in the construction of the tube. In weakly infants, or those much relaxed in strength by acute disease, special attention should be paid to these points, as such children will often refuse to take the bottle, if they find any difficulty in drawing up the milk. Excellent *F. B.* are now made by many different manufacturers, and are sold at prices which place them within the reach of the poorest. Among them may be mentioned, for its comfort, efficiency, and cleanliness, the *Mame F. B.* (Fig. 172), recently patented in this country, and manufactured in Brooklyn by Mr. C. B. Dickinson. The *Alma Mater*, *Praxent*, and other *F. B.* were formerly largely imported from England, but, owing to the heavy duty charged on them, and the perfection attained by American manufacturers, this article is now but occasionally imported from Europe. Imp. duty:

Fig. 172 — *MAME* FEED-BOTTLE.

*F. B.* in glass, india-rubber, and wood, 40 per cent.

**Feed-Pipe,** a pipe which supplies the boiler of a steam engine, etc., with water.

**Feed-Pump,** the force-pump which supplies the boiler of an engine with a quantity of water equal to that removed in the form of steam, by the brine-pump, or other source of outlet.

For the common *F. P.* has been substituted for the last few years a very ingenious contrivance (Fig. 173), invented by M. Giffard, known as *Giffard injector*, and which may be described as follows: A pipe, A, communicates with the upper part of the boiler, containing the steam; another pipe, B, is in

communication with the lower part of the boiler, containing the water. These two pipes end at a small distance from each other, in the empty room, F, which communicates freely with the exterior air by lateral openings; there is, therefore, between them, an interruption of continuity, from which it results that the steam on one side and the water on the other can flow out from the boiler to the exterior by the two pipes A and B and through the chamber F. But the steam escaping with great force by the extremity C of the pipe A, hurries away with it by friction the air which surrounds it, and so produces a kind of vacuum; this vacuum is filled by water from a neighboring reservoir in which is immersed the

Fig. 173 — FEEDING-PUMP. (*Giffard injector*)

small lateral pipe G, and that water aspirated through the pipe G is at its turn taken away by the flow of steam. From this results a continual aspiration of water through the pipe G, and at the same time a continual projection of a mixture of water and steam by the opening which is at the top of the chamber F. That mixture of water and steam constitutes an animated projectile of great velocity, which comes to engage itself directly in the superior extremity of the pipe B, and which not only opposes the escape of water from the boiler by that pipe, but drags it with it into the boiler. The boiler, therefore, is continually fed by the rushing of the water that the jet of steam at C attracts through the pipe G. A conically pointed rod, D, engaged into that part of the pipe A which terminates at C, is provided with a screw and handle which permits to lower or raise it, and so to narrow more or less the orifice of escape of the jet of steam, as to give it the desired intensity. The use of the pipe H is to collect the small quantity of water which might miss the orifice of entry of the pipe B.

**Feejee or Fiji Islands,** a group of 225 islands in the S. Pacific Ocean, 1,100 m. N. of New Zealand, situated in lat. 15° 45' to 19° 10' S., lon. 175° to 177° W., extending 300 m. from E to W., and

240 m. from N. to S., 80 of which are said to be inhabited. The principal are Viti Levu (Great Feejee) and Vanua Levu (Great Land), each about 300 m. in circumference. Vegetation is remarkably luxuriant, the chief products being the bread-fruit tree, banana, plantain, cocoa-nut, sugar-cane, and arrow-root. Cotton, sugar, pearl-shells, indian corn, Bêche-de-mer, and copra and cocoanut-nut oil are the chief exports. The capital is Suva, on the S. coast of Viti Levu. These islands were formally ceded to Great Britain in 1874. The European pop. in 1877 amounted to 1,569.

**Feet**, a commercial name given to the 25 small plates of tortoise-shell, from the edges of the carapace, the superior plates being called "the head."

**Fell**, a skin; the hide of an animal.

**Feller**, a sewing-machine attachment for making a felled seam; that is to say, one in which two edges being run together are folded over and stitched.

**Felling Timber**. When a full-grown tree is cut down it is said to be felled; but this term is never applied to young trees or bushes, undergrowth, or hedges, which are said to be rooted out or cut over. Much has been written respecting the proper season for felling trees; some arguing in favor of midwinter and others in favor of midsummer. The question principally turns upon the quantity and the value of the soft or outer wood in the trunk of the tree to be felled, known by foresters and carpenters as the sap. As this sap or outer wood is the only portion of the trunk in which the sap or juices of the tree circulate, it is evident that if no value be set upon it the tree may be cut down at any season, because the truly valuable part of the trunk, the mature timber, is impermeable to the sap in its ascent through the soft wood, and is, therefore, in the same state at every season of the year. On the other hand, where much value is attached to the soft or outer wood, where this outer wood is wished to be made as valuable as possible, or where, as in the case of comparatively young trees, the greater part of the trunk consists of sap-wood, felling ought to take place when there is least sap in the course of circulation. This season is, without doubt, midwinter, which, all other circumstances being equal, is unquestionably the best season for felling timber; the next best being midsummer, when the sap is chiefly confined to the young shoots, the circumference of the soft wood, and the bark; as the worst is the spring, just before the development of the buds, when the tree is fullest of sap, and receiving constantly fresh supplies from the root, and the autumn, immediately before the fall of the leaf, when there is a superabundance of sap, from its being as it were thrown out of employment by the falling of the leaf. In general, all the soft woods, such as the elm, lime, poplar, willow, etc., should be felled during winter; hard woods, like the oak, beech, ash, etc., when the trunks are of large size, and valued chiefly for their heart-wood, may be felled at any time.

**Fellmonger**, a dealer in hides; a dresser of skins; a part of the business of the fellmonger is to separate the wool from the sheep's skin, the wool being sold to the wool-staplers, and the pelts, or stripped skins, sent to the leather-dressers and parchment-makers.

**Felloe**, the rim of a wheel, or one of the angular segments. See **FELLY**.

**Fellow**, to match; one of a pair.

**Fellow-Craft**, a freemason of the second rank; one above an entered apprentice.

**Fellowship**, a companionship or guild; an association.

**Felly**, a segment of the rim of a wooden wheel. When the perimeter is in one or two portions of bent stuff, it is a *rim*. See **FELLOE**.

**Felspar**, a very abundant silicious mineral, of which there are several varieties, displaying elegant and varied iridescent colors. So far as it relates to manufacturing processes, it is chiefly valuable in being the basis of certain kinds of clay, especially the *kaolin clay* used in the porcelain manufacture.

**Felt** [Fr. *feutre*; Ger. *Filz*], a kind of stuff resembling coarse cloth, made of hair or wool, without spinning or weaving. The fur of the hare, rabbit, seal, beaver, and the wool of the sheep, are the materials chiefly used for making *F*. The hairs and loose flocks of wool are thoroughly mixed together by an operation called *bowing*, which depends on the vibrations of an elastic string; when, in consequence of their anatomical structure, they become matted together. This effect cannot be produced with silk, cotton, flax, or hemp. *F*. is used for cloth, clothing, socks, slippers, boot and shoe soles and insoles, hats, gloves, carpets, table-covers, saddle-cloths, elastic blankets for printing-presses, lining between the planking and copper sheathing of ships, polishing-wheels, hammers of grains, covers of books, etc.—*Felted sheathing*, for covering steam-boilers, etc., is made of cheap woollen refuse, worked up into a kind of pulp, and beaten to the requisite degree of thinness and hardness.—*Roofing felt* is similar to sheathing felt in substance, but is saturated with asphalt, pitch, or coal-tar, to render it impervious to water.

*Imp. duty*: adhesive felt for sheathing vessels, free; felt exclusively of hair, 30 per cent; roofing felt, 20 per cent; end-less felts, for paper or printing machines, or "machine blanketing," 20 cts. per lb. and 55 per cent; carpeting felt (see **CARPET**); hatters' felling (see **WOOLLENS**, **HATS** OF).

*Felling* is the process of matting or uniting different substances into one compact mass. The first step towards making felt is to mix, in the proper proportions, the different kinds of fibres intended to form the stuff; and then, by the vibratory strokes of the bowstring, to toss them up in the air, and to cause them to fall as irregularly as possible upon the table, opened, spread, and scattered. The workman covers this layer of loose flocks with a piece of thick blanket-stuff slightly moistened; he presses it with his hands, moving the hair backward and forward in all directions. Thus the different fibres get interlaced, by their ends pursuing ever tortuous paths; their vermicular motion being always, however, root foremost. As the matting gets denser, the hand pressure should be increased, in order to overcome the increasing resistance to the decussation. A first thin sheet of soft, spongy felt being now formed, a second is condensed upon it in like manner, and then a third, till the requisite strength and thickness be obtained. These different pieces are successively brought together, disposed in a way suitable to the wished-for article, and united by continued dexterous pressure. The stuff must be next subjected to the fulling-mill.

**Felt Cuttings**, clippings from the manufacture of druggets, caps, leggings, etc. They are collected, sold, boiled down, felted over again, and made into felt caps, etc.

**Felted Sheathings**. See **FELT**.

**Felt Hats** are made of felted fabrics, whether of fur, hair, or wool.

**Felting Furs** are furs employed in hat-making, such as beaver, muskrat, etc.

**Feltings**, the collective name for felt fabrics.

**Felucca**, a small coasting vessel in the Mediterranean, carrying two masts with lateen sails; often propelled with oars as well as sails.

**Feme Sole Trader**, in law phraseology, a married woman who trades and deals on her own account independently of her husband.

**Fen**, a moor or marsh.

**Fence**, a rail or bordering protection for a field, or estate, to keep off intruders; live fences are hedges of quickset. — In wood-working, an adjustable guard-plate or edge on a gauge, by which the distance of the groove from the guide-edge is regulated. — The arm of the hammer-spring of a gun-lock. — A slang term for a receiver of stolen goods. — To thrust, parry, or guard off a blow.

**Fencing**, wooden or metallic casing, as a protection for machinery in factories, to prevent injury to the workmen about the machinery.

**Fend**, to ward off.

**Fender**, a thick piece of rope or solid wooden guard or protection hung over the side in vessels, to prevent injury to the bulwarks, etc., by chafing or collision. — A solid or open ornamented metal casing placed before a fireplace, for enclosing the cinders and ashes of the grate.

**Fenks**, the ultimate refuse of the blubber of the whale, which forms an excellent manure when available, and might be used in the manufacture of Prussian blue, and also for the production of ammonia.

**Fennel**, an umbelliferous plant, the *Anethum feniculum dulce*, cultivated in Europe as a pot-herb, and for the seeds and essential oil obtained from them. The seed is used in the manufacture of gin, and in medicine as a carminative. Another species, the common fennel, *Feniculum officinale*, is cultivated in gardens as a garnish for fish, etc., and as a pot-herb for flavoring sauces. The Giant Fennel, *Ferula communis* (Fig. 174), a native of the Mediterranean region, growing to a height of 10 to 15 feet, is very ornamental in single specimens in a large garden.

**Fenugreek**, a plant, native of the S. of France, the *Trigonella fenum Græcum*, the seeds of which are emollient. Poultices made of the flour are employed in veterinary practice.

**Fer-blanc**, the French word for tin.

**Ferding**, a small money of account in the Russian ports of the Baltic; the 80th part of the rix-dollar.

**Ferment**, the substance which is essential to the process of fermentation. It is either naturally present in the fermentable juice, as in the grape, or it is added, as in the manufacture of beer, where yeast constitutes the ferment. Ferments are of an albuminous or glutinous character; the presence of nitrogen seems essential in their composition, hence they are classed by chemists among azotized compounds, which in a moist state putrefy and suffer decomposition. It seems, however, now proved that fermentation is excited by living organisms,—fungi and infusoria. See COMBRESSED YEAST AND FERMENTATION.

**Fermentation** is a peculiar chemical metamorphosis of a complex organic substance, by a transposition of its elements and the agency of an external disturbing force. *F.*, according to the theory proposed by Liebig, is a metamorphosis by which the elements of a complex molecule group themselves so as to form more intimate and stable compounds. It is excited by the contact of all bodies the elements of which are in a state of active decomposition or *F.* The substances which promote *F.* are termed *ferments*, and among these the principal are gliadin,

gluten, vegetable albumen, and all nitrogeous substances in a state of spontaneous decomposition or *F.* *Yeast*, the ferment most commonly employed for inducing the vinous *F.*, is such a substance in an active state of putrefaction, and whose atoms are in continual motion. Putrefying animal substances are equally capable of exciting the same action. If we add to a solution of pure sugar an albuminous substance, a caseous or fleshy matter, the development of yeast becomes manifest, and an additional quantity of it is found at the end of the operation. Thus, with nourishment, ferment engenders ferment. It is for this reason that a little fermenting must, added to a body of fresh grape-juice, excites *F.* in the whole mass. These effects are not confined to alcoholic (vinous) *F.* The smallest portion of sour milk, of sour dough, or sour juice of beet-root, of putrefied flesh and blood, occasions like alterations in

Fig. 174. — GIANT FENNEL.

fresh milk, dough, juice of beet-root, flesh and blood. But further, and which is a very curious circumstance, if we put into a liquid containing any fermenting substance another in a sound state, the latter would suffer decomposition under the influence of the former. If we place urea in the presence of beer-yeast, it experiences no change; while if we add it to sugar-water in a fermenting state, the urea is converted into carbonate of ammonia. We thus possess two modes of decomposition; the one direct, the other indirect.

**Vinous *F.* and Acetous *F.*** When certain vegetable substances are dissolved in water, and subjected to a due temperature (between 65° and 85°), they undergo a series of changes which terminate in the production of alcohol or spirit; these changes constitute the phenomena of *vinous F.* Sugar and some ferment are essential to the process; and during the formation of the alcohol the sugar disappears, and carbonic acid is more or less abundantly evolved. The simplest case of *vinous F.* is that of *must*, or of the expressed juice of the grape, which, when exposed, either in close or open vessels, to a temperature of about 70°, soon begins to give off carbonic acid, and to become turbid and frothy; after a time a scum collects upon the surface, and a sediment is deposited; the liquor which had

grown warm gradually cools and clears, loses its sweet taste, and is converted into *wine*. The chief component parts of must are water, sugar, mucilage, gluten, and tartar. During the *F.* carbonic acid escapes, the sugar disappears, and with it the greater part of the mucilage; the gluten chiefly forms the scum and a portion of the sediment; and the tartar, originally in solution, is thrown down in the form of a colored deposit. It appears, therefore, that the new products, which are *alcohol* and *carbonic acid*, are principally formed at the expense of the sugar; and Gay Lussac's experiments have shown that 45 lbs. of sugar are resolved, in the process of *F.*, into 23 of alcohol and 22 of carbonic acid. Sugar and water alone will not ferment; the ingredient requisite to the commencement of the change is the gluten, which absorbs in the first instance a little oxygen from the air, becomes insoluble, and induces the subsequent changes. The reason why grapes never ferment till the juice is expressed, seems to depend upon the exclusion of air by the husk or membranes; and if grapes be bruised in a perfectly close vessel, carefully excluding oxygen, the juice undergoes no change; so that the mere breaking down of the texture of the fruit is insufficient. But a very short exposure of the pulp to air is sufficient to induce that change in the juice which leads on to *F.*, and which is afterward independent of the further contact of air, the evolution of carbonic acid being exclusively referable to the decomposition of sugar. In *beer*, the alcohol is derived from the sugar, original and produced, of the malt. When wine is exposed to air and a due temperature, a second *F.* ensues, which is called *acetous F.*, and which terminates in the production of *vinegar*. During this process oxygen is absorbed, and more or less carbonic acid in most cases evolved; but the apparent cause of the formation of vinegar is the abstraction of hydrogen from the alcohol, so as to leave the remaining elements in such proportions as to constitute *acetic acid*. Thus alcohol is theoretically constituted of charcoal, water, and hydrogen, and acetic acid of charcoal and water only; the oxygen of the air, therefore, converts the hydrogen of the alcohol into water, and so effects the change into vinegar.

A very remarkable circumstance connected with *F.* is that it is always accompanied by the development of microscopic living organism, — fungi and infusoria. "So constantly, indeed, is this the case, that many chemists and physiologists regard these organisms as the existing cause of *F.* and putrefaction; and this view appears to be corroborated by the fact that each particular kind of *F.* takes place most readily in contact with certain living organisms." (*Fonones*.) Thus the vinous or alcohol-producing *F.* is accompanied, or caused, by two fungi, called *Torula cerevisia* and *Penicillium glaucum*; the acetous or vinegar-producing *F.* by *Torula aceti*; the lacteous *F.* (souring of milk) by *Penicillium glaucum*; etc. Of late years these latter views as to the cause of *F.* have been accepted by most of the scientific world, notwithstanding the opposition they experienced from so powerful an antagonist as Liebig. From the researches of Pasteur, the distinguished author of the modern theory of *F.*, as opposed to the chemico-physical theory of Liebig, it appears that when yeast is placed in a solution of sugar and water, or in a solution of sugar and water containing albuminous substances, under proper conditions as to temperature, the *F.* that ensues is due to the process of growth taking place in the yeast plant; the new cells of which, in assimilating part of the sugar and converting it into cellulose and fat, cause, at the same time, the breaking up of the sugar molecule, and resolve it into the more stable combinations of alcohol and carbonic acid. In order that the ferment of fungus should grow it is essential that, in addition to the cellulose and fat, it should be supplied with ammoniacal salts and soluble phosphates. These are generally present in the liquid about to be fermented; but when yeast is added to pure sugar and water it lives at the expense of the sugar, and of the nitrogenous and mineral substances contained within itself. Speaking of the influence of oxygen on the development of yeast on alcoholic fermentation, Pasteur states that ready-formed yeast can germinate and grow in a liquid containing sugar and albuminous matters, even when oxygen is completely excluded. The quantity of yeast formed, however, in this case is but small, and the *F.* goes on slowly; nevertheless, a large quantity of sugar disappears (sixty to eighty parts to one part of yeast). If the air has access to a large surface the *F.* goes on quickly, and a much larger quantity of yeast is formed in proportion to the quantity of sugar which disappears. In this case, also, oxygen is absorbed by the yeast, which grows quickly, but does not act so decidedly as a ferment, inasmuch as only four to ten parts of sugar disappear for one part of yeast produced. When the air is excluded the same yeast again acts as a powerful ferment. Pasteur, therefore, infers that yeast which acts as a ferment in the absence of air abstracts oxygen from the sugar, and that upon this deoxidizing power its action as a ferment depends. The violent activity of the yeast at the commencement of the *F.* is due to oxygen dissolved in the liquid. In liquids containing albumen (yeast and water, etc.), yeast likewise grows, though sparingly, even if the solution does not contain a trace of sugar, provided there is a sufficient access of air. But if the air is excluded this does not take place, even though the liquid may contain, besides albumen, a non-fermentable

sugar, such as milk sugar. The yeast formed in a liquid not containing sugar possesses all the properties of a ferment, and excites *F.* in a solution of sugar excluded from the air. Similarly, Pasteur regards putrefaction as a kind of *F.*, set up and maintained by an animal organism, or ferment belonging to the genus *Vibrio*. Putrefaction, when taking place in contact with the air, is always accompanied by decay or *cremation*. The abandonment of the old theory as to the nature of *cremation*, viz., that it consisted in the gradual combustion of decaying organic matters by atmospheric oxygen, has been necessitated by the experiments of Pasteur, Schröder, and others, which have conclusively established the facts that organic substances are not oxidized by perfectly pure air, and that their decomposition and subsequent destruction are due to the presence in the air of the sporules or seeds of certain low organisms. Pasteur cites numerous instances corroborative of the statement that perfectly pure oxygen fails to affect, save to a very limited extent, organic substances. In one case an aqueous infusion of yeast mixed with sugar was enclosed in a sealed flask with double its volume of air, which had been previously deputed by being made to pass through a red-hot tube. At the end of three years the liquid (which had during part of the time been kept at a temperature of from 25° to 30° C.) was found to be perfectly fresh and transparent, and the air when examined gave 18.1 vols. of oxygen, 80.5 vols. of nitrogen, and 1.4 of carbonic acid. Under the same conditions urine and milk, whether fresh or previously boiled, showed minute traces only of oxidation; crystals of uric acid and phosphates formed in the urine, but the milk was unaltered, having preserved its alkaline reaction, and showed no disposition to curdle. Very different, however, was the result, when either of the above substances was enclosed with ordinary air. It was then found that in a few days the whole of the oxygen was absorbed, carbonic acid being at the same time simultaneously formed. A certain quantity of moistened oak sawdust kept in contact with ordinary air for a fortnight was found at the end of that time to have absorbed 140 cubic centimetres of oxygen; whilst the same amount of sawdust enclosed with an equal volume of purified air had removed only a few cubic centimetres of the gas in a month. In the former experiment a microscopic film of mycelia and spores of *Mucidinea* formed on the sawdust. From numerous experiments of a like nature with the above, and attended with analogous results, chemists and physiologists now generally regard *cremation* as effected by agencies similar in character to those which produce *F.* and putrefaction.

The entire absence of the exciting causes — warmth, air, and moisture — leaves even those substances which under ordinary circumstances are most liable to change in a state in which they may remain for an almost indefinite period without perceptible alteration. Thus, animal substances in a frozen or dry state do not undergo decomposition, nor does a solution of sugar or the juice of grapes (must) when perfectly excluded from the air; but on the mere exposure of these substances to warmth, moisture, or atmospheric air, putrefaction or *F.* immediately commences. Remove the cork from the bottle of "capillaire" on the parlor sideboard, or pierce the skin of one of the grapes on the dessert table with a needle, and these bodies, which would have otherwise suffered no change for weeks, or even months, will soon exhibit symptoms of spontaneous decomposition. The knowledge of this fact has been practically applied to the preservation of animal and vegetable substances for food. Even the most putrescible of these may be preserved for an unlimited period by enclosure in metallic cases, or glass bottles, from which the air has been completely removed and excluded. — The important duties which *F.* or putrefaction performs in the economy of our globe, and in several of the arts of life and civilization, have long rendered the development of its principles an object of the highest interest and importance, both in a scientific and practical point of view. In its most extended sense, this subtle process of nature, though occasionally productive of injurious effects, may be regarded as one of the most necessary and beneficial with which we are acquainted. Like the labors of a scavenger, it speedily removes from the surface of our globe those matters which would otherwise remain for some time without undergoing decomposition. It either dissipates in air, or reduces to more fixed and useful forms of matter those organic substances which, by their presence, would prove noxious, or, at all events, useless to the animal and vegetable kingdoms. It is the giant power that cleans the Augean stable of nature, at the same time that it provides some of the most esteemed articles of utility and luxury for the well-being and enjoyment of man.

**Fermented Liquor**, a name applied in commerce, and in internal revenue laws, to beers, ales, porters, and other similar liquors obtained by subjecting certain grains, fruits, or vegetables to the process of fermentation, the proportion of alcohol in such liquors being much less than in those which are obtained by distillation.

**Fernandina**. See **FLORIDA**.

**Fernandina, Ferrandine**, a stuff made of silk and wool.

**Ferret**, an animal of the weasel tribe (*Mustela fero*), kept for the purpose of destroying rats, etc., in corn-stacks and out-buildings -- In glass-making, an iron used to make the rings at the mouths of bottles, or to try the melted matter. — In French, a tag for a lice or point.

**Ferrottype**, a photographic process which is substantially as follows: A plate of sheet-iron, after being covered with a surface of black Japan varnish, is immersed in collodion, and after a time in the silver solution. It is then placed in the holder, and exposed in the camera.

**Ferrule**, a metal ring or case, fixed on the handle of a tool, or at the end of a stick or umbrella, to prevent the wood from splitting.

**Ferry**, the place in a river, lake, or harbor where a boat plies for the conveyance of goods or passengers from shore to shore. "In the U. States, ferries are established by legislative authority, exercised either directly or by a delegation of powers to courts, commissioners, or municipalities. Without such authority no one, though he may be the owner of both banks of the river, has a right to keep a public ferry. The owners of ferries are common carriers, and liable, as such, for the carriage of the goods and persons that they receive on their boats. They may determine when and how often, and upon what terms, their boats shall cross the river, and what they will transport; but all these things they must do by general rules, without favoritism or arbitrary exception." — *Zell's Encyclopedia*.

**Ferry-Boat**, a boat employed in crossing a ferry.

**Fertile**, rich or fruitful; having abundant resources.

**Fertilizer**, a manure; an application to the soil, organic or inorganic.

**Festival**, a holiday; a day set apart for rejoicing, public or private.

**Festoon**, a kind of ornamental hanging drapery, suspended in a curve with ends passed over; a garland of flowers.

**Fetch**, to obtain or bring, as a price.

**Fetlock-Boot**, a protection or support for the pastern joints of horses.

**Fetter**, a shackle or chain for the feet; iron links for spanning horses' feet, when grazing in open grounds, to prevent them straying to a distance.

**Feu**, the French word for fire.

**Feuillage** [Fr.], foliage; a row of leaves; branched work.

**Feuille** [Fr.], a leaf; also, a leaf, or sheet of paper.

**Feuille-Morte**, the color of a faded leaf.

**Feuilleton**, that part of a French newspaper devoted to literary or dramatic criticism.

**Feuillets**, the projecting points of the triangular facets in a rose-cut diamond, whose bases join those of the triangle of the central pyramid.

**Feuillette** [Fr.], a half-hoghead.

**Feverfew**, the popular name of *Pyrethrum parthenium* (Fig. 175), a wild plant, a decoction of which is, in some countries, a favorite popular remedy for slight fevers. It contains much tannic acid, and in Germany has been usefully employed in tanning and currying leather.

**Fez**, a red cap, made of felt, worn in Turkey, Greece, etc.

**Fiacre**, a French hackney-coach.

**Fiars**, the average prices of grain legally fixed for the year in Scotland.

**Fiasco**, a liquid measure of Italy; for wine about four pints, and for oil somewhat less.

**Fibre**. This term, as popularly and commercially used, includes the hair and wool of quadrupeds, the threads of the cocoons of silk-worms, etc., the fibres of the leaves of plants and of their inner bark, the elongated cells or hairs connected with the seeds of plants, and the ordinary materials used in making cordage and textile fabrics. Mineral substances are called fibrons in structure, even when it is impossible to detach the apparent fibres. The only fibrous mineral which has been used for textile fabrics is asbestos (q. v.), but that only to a very limited extent. The animal substances used are divided into two classes, — the first including hair and wool, and the second the silk of cocoons. Nearly all textile fabrics are made from the first, and the wool of the sheep is the most important division of the class. The hair of the goat, alpaca, camel, bison, and other animals is also used. The hair of most animals is, however, in general, too short to allow of its being used for textile manufacture. The vegetable kingdom yields the largest number of useful fibres, which are obtained from natural orders very different from each other. From exogenous plants, fibres are obtained from the inner bark, as in the case of flax, hemp, etc., and from the hairs of the fruit, as in cotton. In endogenous plants, the fibre is sometimes obtained from the fruit, as in the cocoa-nut fibre. The spathe of some palms is also used. Some of the slender palms, called rat-

Fig. 175. — FEVERFEW.

tans, and the bulrush, etc., are much used, on account of their fibrous nature, for wicker-work, chair-bottoms, and similar purposes. The most valuable fibres obtained from endogenous plants come from the leaf or leaf stalk. The fibres of the bark of exogens are readily separated, usually by steeping or continually moistening with water. As this process injures the color of endogenous substances, the fibres are generally separated by beating or passing between rollers. Fibres obtained from fruits, as cotton-fibre, like the wool and hair of animals, exist naturally in a separate state, and only require to be collected and cleaned. Among the useful vegetable fibres those of flax, hemp, and cotton have long held the first place.

The principal additions, of late years, have been New Zealand flax, jute, Sunn or Sunn hemp, coir, Pita flax, Abaca or Manilla hemp, Chinese grass, Esparto, Alfa, American jute, etc. All the useful fibres are noticed under their particular names.

**Fibula**, a needle used by surgeons for sewing up wounds.

**Fichu** [Fr.], a sort of three-cornered neckerchief worn by ladies.

**Fictile**, moulded into form by art; manufactured of clay by the potter.

**Fid**, a tapered wooden pin, used by seamen in splicing large ropes, opening eyes, or holes, etc.; an iron support passed through a hole in the heel of a mast.

**Fiddle**, a stringed musical instrument. See VIOLIN.

**Fiddle-Block**, a block with two sheaves, one over the other, the lower one smaller than the upper.

**Fiddle-Bow**, **Fiddle-Stick**, the stringed bow with which a fiddler draws sound from his instrument.

**Fiddle-Wood**, a durable wood used for mills framing, carriage-wheels, etc.; the produce of *Citharexylum melanocardium*, a useful timber-tree of the West Indies.

**Field**, a portion of arable land.—The range of an optical instrument; the space visible in it at one view.

**Field-Bed**, a portable or folding camp-bed.

**Field-Book**, a land-surveyor's plotting-book, in which the angles, distances, stations, etc., are noted down for mapping or reference.

**Field-Gun**, a piece of cannon mounted on a two-wheeled carriage, and drawn by horses, which can be carried into the field of battle, and throws a shot of from 6 to 12 pounds.

**Field-Roller**, a wooden or iron cylinder, drawn upon a ploughed field to mash the clods and level the ground.

**Fife**, a very small wooden flute or pipe, giving acute piercing sounds, and used as an accompaniment to the drum.

**Fife-Rail**, the rail round a ship's mast.

**Fig** [Fr. *figue*; Ger. *Feig*; It. *jicho*; Port. *figo*; Sp. *Higo*], the fruit of *Ficus carica*, a small tree, rarely more than 20 feet high, indigenous to Asia Minor and Syria. The fig consists of a pulp containing a number of seed-like pericarps enclosed in a rind; and is of various colors, from deep purple to yellow, or nearly white, with a sweet taste. From the ease with which this nutritious fruit can be preserved, it was probably one of the earliest objects of cultivation, as may be inferred from the frequent allusions to it in the Hebrew Scriptures. The tree is now cultivated in all the Mediterranean countries, but the larger portion of our supply of figs comes from Asia Minor, Spain, and the South of France. Those of Asiatic Turkey are considered the best. The trees usually bear two crops, one in the early summer from the buds of the last year, the other in the autumn from those of the spring growth; the latter forms the chief harvest. When ripe the figs are picked and spread out to dry in the sun, those of better quality being much pulled and extended by hand during the process. Thus prepared, the fruit is packed closely in barrels, rush baskets, or wooden boxes, for commerce. The best kind, known as *elemi*, are shipped at Smyrna, where the pulling and packing of figs form one of the most important industries. This fruit still constitutes a large part of the food of the natives of Western Asia and Southern Europe, both in the fresh and

dried state. Medicinally the fig is employed as a gentle laxative, when eaten abundantly often proving useful in chronic constipation; it forms a part of the well-known "confection of senna." Cut open, the fruit is a popular cataplasm for boils and sores, an application as old as the days of Hezekiah. It is recommended as a demulcent in disorders of the throat, being given in the form of decoction. The fig is grown for its fresh fruit (eaten as an article of dessert) in all the milder parts of Europe; and in the U. States, with protection in winter, succeeds well as far north as Pennsylvania. *Imp. duty*, 2½ cts. per lb.; preserved in sugar, brandy, or molasses, 35 per cent.

**Fig-Cake**, a preparation of figs and almonds, worked up into a hard paste, and pressed into round cakes like small cheeses, which is vended about the streets.

**Figure**, a number.—An artist's model.—Any representation made of things in wood, stone, or other solid material.—Amount, price, value; as, the goods were sold at a high figure.—To goffer, to emboss, to ornament a stuff with gold, silk, etc.

**Figure-Head**, a carved bust, statue, or full-length figure, placed over the cutwater or bow of a ship.

**Figured Muslin**, a thin fabric in which a pattern, design, or representation is wrought. See MUSLIN.

**Figure-Weaving**, a process differing from plain-weaving; patterns or designs being produced in the damask, velvet, or other stuff by employing threads of different colors or of different appearance, in the warp or in the weft.

**Fil** [Fr.], thread, hair, wire; a small twist of silk, hemp, or flax.

**Filament**, a string; a long fibre or fine thread.

**Filasse** [Fr.], hemp or flax ready to be spun.

**Filature**, a silk-yarn, or cotton-twist, manufactory; a workshop where silk is reeled from cocoons and spun.

**Filbert**, the fruit of the cultivated hazel (*Corylus avellana alba*). The filbert is not thicker than the common nut, but is at least double the length, with a corresponding kernel. The largest of the species is the cob-nut, which is round. What is called the cluster-nut differs from the others only in the fruit being produced in large clusters at the ends of the branches. Filberts are imported to the U. States, principally from Palermo and Naples, in bags of about 195 lbs.; and from France, in barrels or bags. *Imp. duty*, 3 cts. per lb.

**Filch**, to steal or purloin.

**File** [Fr. *lime*; Ger. *Feile*; It. *lima*], an instrument of iron or forged steel, used to polish or smooth metals, and other hard bodies. A file differs from a rasp (which is chiefly used for working wood, horn, and the like) in having its teeth cut with a chisel whose straight edge extends across its surface, while the teeth of the rasp are formed by solitary indentations of a pointed chisel. According to the form of their teeth, files may be *single-cut* or *double-cut*; the former have only one set of parallel ridges (either at right angles or at some other angle with the length); the latter (and more common) have a second set cut at an angle with the first. The double-cut file presents sharp angles to the field surface, and is better suited for hard metals. Files are also classed according to fineness of teeth, being known (in order of increasing fineness) as *rough*, *bustard*, *second-cut*, *smooth*, and *superfine*, or *dead smooth*. The shapes of files present almost endless varieties. Common forms are: the *flat* file, of parallelogram section, with uniform breadth and thickness, or tapering, or

"bellied"; the *four-square* file, of square section, sometimes with one side "safe," or left smooth; the so-called *three-square* file, having its cross section an equilateral triangle; the *half-round* file, a segment of a circle; the round or *rat-tail* file, a circle; the last three are generally tapered. The *float* file is like the *flat*, but single-cut. There are many others. Files vary in length from three quarters of an inch (watchmakers') to two or three feet and upwards (engineers'). The length is reckoned exclusively of the spike or tang which enters the handle. Most files are tapered; the *blunt* are nearly parallel with larger section near the middle; a few are parallel. The *rifflers* of sculptors and of a few other files are curvilinear in their central line.

Cast-steel is the material chiefly used for *F.*, though the larger and rougher varieties are sometimes made from blister-steel. In manufacture, the blanks are forged from bars that have been tilted or rolled as nearly as possible to the sections required; they are then annealed with great care, and when sufficiently softened are taken out, straightened, if necessary, with hand hammers, and then rendered clean and accurate in form by filing or grinding. They are now ready for cutting. In this process, as performed by hand, the cutter sits before a square stake or anvil, on which the blank, slightly greased, is held (having its tang towards him) by means of two leather straps passed round its ends, and held fast below, one by each foot. He holds in his left hand a short chisel (the edge of which always exceeds the width of the *F.*, placing it on the blank with a slight inclination from him, and beginning near the further end. He strikes the chisel sharply with a hammer; an indentation is thus made, and the steel, slightly thrown up on the side next the tang, forms a ridge. The chisel is then transferred to the uncut surface, and slid from the operator till it reaches the ridge just made; thus the position of the next cut is determined; the chisel is again struck, and so on. (The end part of the *F.* is dealt with separately.) The workman seeks to give his blow as uniformly as possible. Sixty to eighty cuts are made in one minute. After finishing the first *course* of cuts, he proceeds, if the *F.* is to be double-cut, to make the second course, the cuts of the latter being generally somewhat finer. Thus the surface is covered with teeth inclined towards the point of the *F.* If the *F.* is flat and is to be cut on the other side, it is turned over, and a thin plate of pewter placed below it to protect the teeth. Triangular and other *F.* are supported in grooves in lead. In cutting round and half-round *F.*, a straight chisel is applied as tangent to the curve. The round face of a half-round *F.* requires eight, ten, or more courses to complete it. The *F.* is next hardened. Being first covered with a paste to protect the teeth from the direct action of fire, etc. (for instance, passed through beer-grounds to make it sticky, then through a mixture of common salt with roasted and pounded cow's hoof), it is heated to an even red heat, and then suddenly cooled by plunging in cold water or brine. It is removed before cooling throughout, that it may be straightened if necessary (which is done by pressure). Then it is cooled in oil. The tang is next submitted to a softening process, and the *F.*, after being wiped, and the teeth brushed clean, is ready for fixing into the handle and for use.

In England *F.* are chiefly made in Sheffield and Warrington, those of the latter place being generally known as Lancashire *F.* It is remarkable that while many other operations that appear more difficult than *F.*-cutting are now effected by machinery, and while numerous *F.*-cutting machines have been invented, the work continues (in England) to be largely done by hand. This is perhaps partly due to strong opposition on the part of operatives to introduction of machinery, and also to a foolish prejudice in favor of hand-cut *F.* (machine-cut *F.* indeed, are not unfrequently sold as hand-cut), but probably also to the problem of cutting *F.* by machinery being really somewhat difficult. In most of the machines invented for that purpose, the idea has been to construct an iron arm and hand to hold the chisel, and a hammer to strike the blow, and so to imitate, as closely as possible, the manual process. *F.*-making by machinery is extensively and successfully practised in the U. States, which seems to indicate that much of the failure experienced in England is due to the defect in their machinery, of producing extreme regularity in the teeth. This gives rise to complaints by English artisans about *F.* "running in grooves," "clattering," etc. The grooves produced by the *F.* (if double-cut especially) at the beginning of its movement are deepened as it is moved further. With irregular teeth, on the other hand, such as are found in all hand-made *F.*, the grooves made in the first instance have their sides cut away as the *F.* is advanced. The Nicholson *F.* Co., in Providence, Rhode Island, have used, with large and increasing success, a machine which imitates, to some extent, this irregular result of the hand process, cutting the *F.* so that no two spaces are found exactly alike in the entire length. The filing of a flat surface perfectly true is the test of a good

filer; and this is no easy matter to the beginner. The piece to be operated upon is generally fixed about the level of the elbow, the operator standing, and, except in the case of small *F.*, grasping the *F.* with both hands, the handle with the right, the further end with the left. The great point is to be able to move the *F.* forward with pressure in horizontal straight lines; from the tendency of the hands to move in arcs of circles, the heel and point of the *F.* are apt to be alternately raised. This is partially compensated by the bellied form given to many *F.* (which also counteracts the frequent warping effect of the hardening process, by which one side of a flat *F.* may be rendered concave and useless). In bringing back the *F.* for the next thrust it is nearly lifted off the work. Further, much delicacy and skill are required in adapting the pressure and velocity, ascertaining if foreign matters or filings remain interposed between the *F.* and the work, etc. *F.* can be cleaned with a piece of the so-called *rotton-card* (used in combing cotton-wool) nailed to a piece of wood. In *draw-filing*, which is sometimes resorted to, to give a neat finish, the *F.* is drawn sideways to and fro over the work. New *F.* are generally used for a time on brass or cast-iron, and when partially worn they are still available for filing wrought iron and steel.

*Imp. duty:* *F.* and *F.* blanks, rasps and floats, all not over 10 inches long, 10 cts. per lb. and 30 per cent; the same, over 10 inches long, 6 cts. per lb. and 30 per cent.

**Filet** [Fr.], a small thread or fibre; a string or lace.

**FilEUR** [Fr.], a spinner.

**Filibuster**, a sea-robber; an American pirate.

**Filigree**, **Filigrane**, a style of ornamental work in gold or silver, wrought in little threads of the metal intertwisted in eccentric forms and patterns. It is of Eastern origin, and was first introduced into Europe by the Italians. In the East, Sumatra and Java have been celebrated for the high excellence to which they have arrived in the prosecution of this art. When the gold or silver has arrived to a molten state, it is drawn into wire on an anvil, and then twisted. After twisting it is hammered down again into a flat state, and formed into the shape of flowers and leaves. When the *filigree* is finished, it is cleansed by boiling in water with common salt and alum, or occasionally lime-juice. This work is chiefly done in Malta, Sardinia, and the Ionian Islands.

**Fillings**, fragments or raspings of metal, ivory, etc.; particles rubbed off in the process of filing.

**Fillet**, a little band to bind the hair.—Any small timber or scantling equal to, or less than, battens.—A strip of card-clothing.—A little rule or ringlet of leaf gold, drawn over certain mouldings, or on the edges of frames, panels, etc.

**Fillings**, a brewer's term for prepared wort, added in small quantities to casks of ale to cleanse it.—The woof in weaving.

**Fillister**, a plane used for making the outer part of a window-sash fit for receiving the glass.

**Filly**, a young mare.

**Filoché** [Fr.], a large rope used by millers and others.

**Filosedá** [Sp.], a silk and worsted fabric.

**Filoselle**, ferret or floss silk; grosgrain yarn.

**Filter**. See **FILTERING**.

**Filtering-Paper**. See **FILTRATION**.

**Filtration**, **Filtering**, the separation of liquids from substances mechanically suspended in them, by passing them through media having pores sufficiently fine to retain or keep back the solid matter. *F.* is one of the most common and useful of the chemico-mechanical operations of the arts, and its successful performance in an economical and expeditious manner is therefore a matter of the highest importance in almost every branch of human skill and industry in which liquids are employed. Simple in principle, and apparently easily performed, it is, nevertheless, one of those operations which require no less of care than of tact and experience to conduct it with certainty and success. The losses sustained in the laboratory, by defective manipulation in this particular, often

exceed those arising from ignorance and accidents in every other department conducted in it. *F.* is generally resorted to for the purpose of freeing liquids from feculence, dirt, and other foreign matter, and for obtaining them in a clear or transparent state; but, in some cases, it has for its object the collection of the suspended substances, as precipitates, etc., and in others both these intentions are combined. The word "filtration" is absolutely synonymous with *straining*, but in the language of the laboratory it is usually applied to the operation of rendering liquids transparent, or nearly so, by passing them through fine media, as filtering-paper, sand, and the like; whilst the term "straining" is employed to designate the mere separation of the grosser portion, by means of coarse media, flannel, horse-hair cloth, etc., through which they flow with considerable rapidity. *F.* is distinguished from *clarification* by its mere mechanical action, whereas the latter operates by depuration, or the subsidence of the suspended substances or fæces, arising from their gravity being naturally greater than the fluid with which they are mixed, or being rendered so by the application of heat, or by the addition of some foreign substance. — The apparatus, vessels, or media employed for filtration are called *filters*, and are technically distinguished from *strainers* by the superior fineness of their pores. Both strainers and filters act on the same principles as the common sieve on powders; they all, in like manner, retain or hold back the coarser matter, and permit the liquid or smaller and more attenuated particles to pass through.

Fig. 176. — FILTERS.

The term *medium* (plural *media*) is applied to the substance or substances through the pores of which the liquid percolates. The form of filters and the substances of which they are composed are various, and depend upon the nature of the liquids for which they are intended. On the small scale, funnels of tin, zinc, copper, wedgewood-ware, earthenware, glass or porcelain (1, Fig. 176), are commonly employed as the containing vessels. The filtering medium may be any substance of a sufficiently spongy or porous nature to allow of the free percolation of the liquid, and whose pores are, at the same time, sufficiently small to render it limpid or transparent. Unsized paper, flannel, linen, calico, cotton-wool, felt, sand, coarsely powdered charcoal, porous stone or earthenware, and numerous other substances of a similar kind are employed for this purpose. For many liquids that filter easily, and in which the suspended matter is of a coarse and porous nature, it is often sufficient merely to place a little cotton-wool or tow, or a small piece of sponge, in the neck of the funnel; but such an apparatus, from the small extent of the filtering surface, acts either slowly or imperfectly, and soon gets choked up. Filters of un-

sized paper are well suited for all liquids that are not of a corrosive or viscid nature, and are universally employed for filtering small quantities of liquids in the laboratory. A piece of the paper is taken of a size proportionate to the quantity of the liquid to be filtered, and is first doubled from corner to corner into a triangle, which is again doubled into a smaller triangle, and the angular portion of the margin being rounded off with a pair of scissors, it constitutes a paper cone, which is placed on a funnel of proportionate capacity, and is then nearly filled with the liquid. A piece of paper so cut, when laid flat upon the table, should be nearly circular. Filtering paper is sold ready cut in circles of various sizes, which simply require doubling for use. Another method of forming a paper filter, preferred by some persons, is to double the paper once, as above, and then to fold it in a similar way to a fan (2, Fig. 176), observing so to open it and lay it on the funnel that a sufficient interval be left between the two to permit of the free passage of the filtered liquid on its descent towards the receiver. The "plaited filter," as thus formed, is exceedingly useful for general purposes; it exposes the entire surface of the paper to the liquid, and allows filtration to proceed more rapidly than a "plain filter" does. In reference to funnels, it may be remarked that those employed for filtering rapidly should be deeply ribbed on the inside, or small rods of wood or glass, or pieces of straw, or quills, should be placed between them and the paper. The neck or tubular part of the funnel should, in like manner, be deeply ribbed or fluted on the outside, to permit of the free passage of the air, when it is placed in a narrow-mouthed bottle or receiver. When this is not the case, *F.* proceeds but slowly, and the filtered liquid is apt to be driven up the outside of the neck of the funnel by the confined air, and to be continually hissing and flowing over the mouth of the vessel. The breadth of a funnel, to filter well, should be about three fourths its height, reckoning from the throat. When deeper, the paper is liable to be continually ruptured, from the pressure of the superincumbent fluid; and when shallower, *F.* proceeds slowly, and an unnecessarily large surface of the liquid is exposed to the atmosphere, and is lost by evaporation. To lessen this as much as possible, the upper edge of the glass is frequently ground perfectly smooth, and a piece of smooth plate-glass is laid thereon. When paper filters are of large dimensions, or employed for aqueous fluids that rapidly soften the texture of the paper, or for collecting heavy powders, or metallic precipitates, it is usual to support them on linen or calico, to prevent their breaking. This is best done by folding the cloth up with the paper, and cutting the filter out of the two, in the same way as would be done with double paper, observing so to place it in the funnel that the paper and calico may remain close together, especially towards the bottom. The *F.* of small quantities of liquid, as in chemical experiments, may often be conveniently performed by merely placing the paper on the circular top of a recipient, or on a ring of glass or earthenware laid on the top of any suitable vessel. A filter of this kind that will hold one fluid ounce will filter many ounces of some liquids in an hour. — Good filtering-paper should contain no soluble matter, and should not give more than  $\frac{1}{100}$  of its weight of ashes. The soluble matter may be removed by washing it, first, with very dilute hydrochloric acid, and secondly with distilled water. The "Munktell" Swedish filtering-paper is composed

of flax fibres very much crushed and broken, and owes its value to the broken pieces of the fibres filling up the pores, and thus preventing solids from passing through the paper. Rhenish filtering paper is also made from flax, but, in consequence of the more perfect condition of its fibres, is more porous than Munktel's, and therefore inferior to it for filtering purposes. Another kind of Rhenish paper, also of flax, in which the fibres are much torn, is manufactured, and is said to be a useful article, and to allow the rapid passage of fluids through it. The white filtering-papers of English make have a small quantity of cotton mixed with the flax, and the fibres are much torn and crushed; hence they make serviceable filters. — For filtering a larger quantity of a liquid than can be conveniently managed with a funnel, and also for substances that are either too viscous or too much loaded with feculence to allow them to pass freely through paper, conical bags made of flannel, felt, twilled cotton cloth or Canton flannel, linen or calico, and suspended to iron hooks by rings or tapes (3, Fig. 176), are commonly employed. The first two of the above substances are preferable for saccharine, mucilaginous, and acidulous liquors; the third for oily ones; and the remainder for tinctures, weak alkaline lyes, and similar solutions. These bags have the disadvantage of sucking up a considerable quantity of the fluid poured into them, and are therefore objectionable except for large quantities, or when they are to be continued in actual use as filters for some time. On the large scale, a number of them are usually worked together, and are generally enclosed in cases to prevent evaporation, and to exclude dirt from the filtered liquor that trickles down their sides. These arrangements will be noticed further on. — A simple mode of filtering aqueous fluids, which are not injured by exposure to the air, is to draw them off from one vessel to another, by means of a number of threads of loosely twisted cotton or worsted, arranged in the form of a siphon (4, Fig. 176). The little cotton rope at once performs the operations of decantation and *F*. This method is often convenient for sucking off the water from a small quantity of a precipitate.

*F. of Water.* River water, shallow well water, and elatern water, extensively used for water-supply, being in general largely polluted, it is a wise safeguard to employ a filtering process, and its use is often quite imperative if the laws of health are to be respected. The constructing of water-filters is a matter in which invention has been largely exercised. All sorts of porous substances have been called into requisition, as may be seen by a glance at the patent records. Thus, to mention some of these, we have various kinds of stone, sand, gravel, powdered glass, clay, porous sulphur, preparations of iron, charcoal (vegetable and animal), cloth, felt, horse-hair, skins, paper, silicate carbon, sponge, wood, cane, capillary threads, and so on. Vegetable charcoal, we may note, was first employed in 1802, animal charcoal in 1818, and solid carbon blocks in 1831. — In passing now to examine some of the approved forms of domestic filters at present in use, it should be borne in mind that while any of these filters will doubtless purify water both mechanically and chemically, more or less, it is only on condition of their being properly attended to, and the filtering material renovated at intervals depending on its nature and the nature and amount of impurity in the water. The term "self-cleansing," applied to some filters, may have a (limited) true sense, but if understood to imply that a filter, let alone, will go on *ad infinitum* giving pure water, it is quite inapplicable; solid impurities must accumulate and call for removal. The statement, occasionally made, that a filter is "warranted to remove all impurities" from water is absurd, and hardly deserves notice. Absolutely pure water is a thing almost unknown; careful distillation alone will give an approximation to it. Again, the claim that a filter will remove all lime from water is often false; filtration is capable of removing only a small quantity of lime. It must be allowed that sundry points in the process of filtration still remain in some obscurity, and it is a matter of regret that the action of some common filtering agents has not been so fully cleared up by

scientific experiment as others. Still, enough has been ascertained probably to guide to the construction of a filter on rational principles. — In a large proportion of filters, as already indicated, some form or other of carbon is the chief filtering agent. The well-known filters of Lipscombe are cylindrical-shaped covered vessels of glazed earthenware, in which the filtering medium, a mixture of vegetable and animal charcoal, in granular form, is enclosed between two slabs cemented in the case. The upper (glazed earthenware) slab has a central aperture with raised border, and a small perforated basin immediately below it; into this is inserted a sponge to arrest the grosser impurities, which is taken out and cleaned at short intervals. The filtered water passes through the lower (and porous) slab to the reservoir below, which communicates above with the outer air by a narrow tube passing up within to the top of the apparatus, and delivers its water through a tap. — Charcoal in the form of solid finely porous blocks, which can be conveniently brushed and cleaned externally, is now often moulded for filters. The convenient decanter filter, in which the water passes through the block to a central tube (Fig. 177), forms an elegant addition to the sideboard. Sometimes the block is fitted in a movable pan. Again, in the filter shown in 1, Fig. 178, a double *F* is effected, the water passing first through loose charcoal, B, then through a charcoal block, C, supported as shown. The block in this case is said to last longer without cleaning. The movable and perforated earthenware plate, A, which is placed above the charcoal (2, Fig. 178), allows of easy renewal of the latter. The charcoal used in these filters is chiefly of vegetable origin. They are found to remove more or less of organic and inorganic matter dissolved in water. — Fresh animal charcoal has been proved to act powerfully in the removal of organic impurity (considerably more so than vegetable charcoal), as well as of mineral matter. But its reduction of the hardness ceases in about a fortnight, the removal of organic matter continuing even after six months, though to a much less extent, especially if the filter be much used. — A very powerful filtering medium was discovered and introduced many years ago by Mr. T. Spencer. It is called *magnetic carbide*, and consists of protoxide of iron in chemical combination with carbon. It is obtained by roasting hematite iron-ore with granulated charcoal for twelve to sixteen hours at a dull red heat. Mr. Spencer considers the purifying property of the oxide to be due to its power of attracting oxygen to its surface, without the latter being acted upon, the oxygen attracted being then changed into ozone, by which the organic matter of the water is consumed. The magnetic carbide is used in granular form. This filter gained prize medals at the London and Paris exhibitions, and its efficiency was demonstrated by the *Lancet* Sanitary Commissioners' report on filters in 1867. — The only other system we shall here notice is that in which spongy iron is used. This substance is metallic iron which has been reduced from an oxide without fusion. It is in a spongy or porous state of extremely fine division. Its remarkable purifying action on water was dis-

scientific experiment as others. Still, enough has been ascertained probably to guide to the construction of a filter on rational principles. — In a large proportion of filters, as already indicated, some form or other of carbon is the chief filtering agent. The well-known filters of Lipscombe are cylindrical-shaped covered vessels of glazed earthenware, in which the filtering medium, a mixture of vegetable and animal charcoal, in granular form, is enclosed between two slabs cemented in the case. The upper (glazed earthenware) slab has a central aperture with raised border, and a small perforated basin immediately below it; into this is inserted a sponge to arrest the grosser impurities, which is taken out and cleaned at short intervals. The filtered water passes through the lower (and porous) slab to the reservoir below, which communicates above with the outer air by a narrow tube passing up within to the top of the apparatus, and delivers its water through a tap. — Charcoal in the form of solid finely porous blocks, which can be conveniently brushed and cleaned externally, is now often moulded for filters. The convenient decanter filter, in which the water passes through the block to a central tube (Fig. 177), forms an elegant addition to the sideboard. Sometimes the block is fitted in a movable pan. Again, in the filter shown in 1, Fig. 178, a double *F* is effected, the water passing first through loose charcoal, B, then through a charcoal block, C, supported as shown. The block in this case is said to last longer without cleaning. The movable and perforated earthenware plate, A, which is placed above the charcoal (2, Fig. 178), allows of easy renewal of the latter. The charcoal used in these filters is chiefly of vegetable origin. They are found to remove more or less of organic and inorganic matter dissolved in water. — Fresh animal charcoal has been proved to act powerfully in the removal of organic impurity (considerably more so than vegetable charcoal), as well as of mineral matter. But its reduction of the hardness ceases in about a fortnight, the removal of organic matter continuing even after six months, though to a much less extent, especially if the filter be much used. — A very powerful filtering medium was discovered and introduced many years ago by Mr. T. Spencer. It is called *magnetic carbide*, and consists of protoxide of iron in chemical combination with carbon. It is obtained by roasting hematite iron-ore with granulated charcoal for twelve to sixteen hours at a dull red heat. Mr. Spencer considers the purifying property of the oxide to be due to its power of attracting oxygen to its surface, without the latter being acted upon, the oxygen attracted being then changed into ozone, by which the organic matter of the water is consumed. The magnetic carbide is used in granular form. This filter gained prize medals at the London and Paris exhibitions, and its efficiency was demonstrated by the *Lancet* Sanitary Commissioners' report on filters in 1867. — The only other system we shall here notice is that in which spongy iron is used. This substance is metallic iron which has been reduced from an oxide without fusion. It is in a spongy or porous state of extremely fine division. Its remarkable purifying action on water was dis-

covered by Prof. Gustav Bischof; and experiments made with his filters showed that their power both of removing organic matter and reducing the hardness of water even increased during upwards of eight months' constant use. The general form of the filter is represented in Fig. 179. An inner vessel containing the spongy iron is supported in a case, which, below, contains some prepared sand, a regulator, A, and a receptacle, C, for filtered water (with tap, not shown). The unfiltered water, B, is in this form supplied from a bottle which is inverted into the upper part of the inner vessel (a method familiar to chemists). After passing through the spongy iron, the water ascends

Fig. 179. — BISHOP'S SPONGY IRON FILTER.

A, regulator; B, unfiltered water; C, filtered water.

through an overflow-pipe in the direction of the arrows; the object of this is to keep the spongy iron, when once wet, constantly under water, as otherwise it is too rapidly oxidized. The object of the prepared sand (which is generally in three layers, viz., pyrolusite at the top, then sand, then gravel) is to separate traces of iron retained in solution. The regulator, A, consists of a tin tube, cemented in the position shown; it is open at the inner end, which is below the perforated bottom supporting the sand, and closed by a screw-cap at its outer end. It has also a small lateral perforation, through which alone the filtered water passes into the reservoir. Should the perforations get choked, the screw-cap is removed, and a brush inserted; on starting at first, too, the cap is unscrewed, that the materials may be well washed out without soiling the lower reservoir. With a ball-cock and constant supply of water, the inner vessel is dispensed with. The nature of the action of the metal on organic matter is rather obscure. Mr. Bischof considers there are both reducing and oxidizing agencies constantly at work, and that the oxides of iron, being present in their nascent state, must be very energetic in their action. Probably ferric hydrate, the last product of oxidation, takes an active part in separation of the organic matter, transferring oxygen to it. Again, spongy iron is known to be very energetic in precipitating any lead or copper. Its reduction of the hardness of water presents some difficulty. This filter, we may

add, recently gained the prize medal for general excellence given by the Sanitary Institute of Great Britain.

**F. of Oils.** Oils are filtered on the small scale, through cotton-wool, or unsized paper, arranged in a funnel; and on the large scale, through long bags, made of twilled cotton cloth (Canton cloth). These bags are usually made about 12 or 15 inches in diameter, and from 4 to 8 feet long (Fig. 180), and are enclosed in bottomless casings, or bags of coarse canvas, about 5 to 6 or 8 inches in diameter, for the purpose of condensing a great extent of filtering surface into the smallest possible space. A number of these double bags are connected with corresponding holes in the bottom of a block-tin or tinned-copper cistern, into which the oil to be filtered is poured. The mode in which these bags are fastened to the cistern is of the utmost importance, as on the joint being close and secure depends the integrity of the apparatus. The bags are surrounded by a wooden screen fitted up with doors for the purpose of keeping off the dust; and the bottom of the apartment is furnished with large steam-pipes, by which a proper temperature may be kept up in cold weather. The use of heat should, however, never be had recourse to when it can be avoided, as, although it vastly increases the rate of F., the oil so filtered is more apt to become opaque in cold weather than when the process is conducted at the natural temperature of the atmosphere. This is particularly the case with castor oil and sperm oil. In practice, it is more convenient to have a number of small cisterns at work (say 50 or 100 galls. each), than one or two larger ones, as any accident that may occur is more easily remedied, and that without stopping the whole operation. When cotton-cloth bags are employed without being "creased," or enclosed in others of canvas, they should not be longer than about 3 or 4 feet, and not wider than about 5 or 6 inches when filled. When larger they are dangerous. — A convenient method of filtering a single cask of oil is, to insert the pipe of a two-way patent filter into the cork-hole (1, Fig. 181), by which means the whole will be filtered as drawn off, without any trouble on the part of the operator. This filter consists of a porous bag stretched over a perforated metallic vessel, nearly the shape and size of the exterior casing, and its edge is tightly screwed between the sides and bottom of the latter, so as to be quite water-tight. The cock communicates with the interior of the perforated plate and filter, and the supply-pipe with the exterior. By this means the interior chamber, which occupies  $\frac{2}{3}$  of the vessel, rapidly fills with filtered oil, and continues full as long as any liquor remains in the cask. This arrangement is also well adapted to the filtration of wines, beer, cordials, porter, and various other liquors. It is unequalled in simplicity and usefulness. The same filter may be removed from cask to cask, with the facility of a common cock.

Fig. 180. — OIL FILTERING-BAGS.

Fig. 181.

**F. of Sirups** is now generally effected on the large scale by passing them through the *creased-bag filter* just described. On the small scale, as employed by confectioners and druggists, they are usually passed through *conical flannel bags* (3, Fig. 176). The *F. of thick sirups* is, however, attended with some difficulty, and it is therefore a good plan to filter them in a somewhat dilute state, and afterwards to reduce them to a proper consistence by evaporation in clean vessels of tinned copper, by steam heat. Sirups, when filtered in a heated state, run well for a time, but the pores of the fabric rapidly get choked, from the thickening of the sirup and partial crystallization of the sugar, occasioned by the evaporation of the aqueous portion from the surface of the bag. This may be partially prevented by enclosing the bag in a metallic casing. On the whole, clarification is preferable for sirups to filtration on the small scale.

They need only be well beaten up while cold with a little white of egg, and then heated; a scum rises, which must be removed as soon as it becomes consistent, and the skimming continued until the liquid becomes clear. Any floating portions of scum that may have escaped notice are easily removed by running the drup through a coarse flannel strainer whilst hot. The most extensive application of the process of *F.* in the arts is in the refining of sugars.

*F. of Tinctures and Vegetable Juices.* They are usually filtered, on the small scale, through *bibulous* or *unsized* paper placed on a funnel; and on the large scale through thin and fine cotton bags. In general, however, tinctures clarify themselves by the subsidence of the suspended matter, when allowed to repose for a few days. Hence it is the bottoms alone that require filtering; the supernatant clear portion need only be run through a small hair sieve, or some other coarse medium, to remove any floating substances, as pieces of straw, etc. When possible, tinctures, spirits, and all similar volatile fluids are better and more economically cleared by subsidence or clarification than by *F.*, as, in the latter way, a portion is lost by evaporation, and the strength of the liquid is thereby altered. — Vegetable juices should be allowed to deposit their feculose portion before *F.* The supernatant liquid will then be often found quite clear. It is only when this is not the case that *F.* should be had recourse to. A small quantity may be filtered through coarse or woollen filtering paper, supported on a piece of coarse calico placed on a funnel; when the quantity is large, one of the *conical* bags before described should be employed. The bottoms from which the clear portion has been decanted should be placed on a separate filter, or else not added until the whole of the other portion has drained through. Vegetable juices are often rendered clear by simply heating them to about 180° or 200° F., by which their albumen is coagulated; they are also frequently clarified by the addition of a little white of egg and heat, in the same way as sirups. A convenient method of straining vegetable infusions and decoctions is, to stretch a square of flannel on a frame or "horse," securing it at the corners by pieces of string (2, Fig. 181). Such a frame, laid across the mouth of a pan, is more easily fed with fresh liquid than a bag, whose mouth is 40 or 50 inches higher. Many vegetable solutions, that from the viscosity of the suspended matter can scarcely be filtered, may be readily clarified with white of egg in the cold, or pass the filter rapidly if a very small quantity of acetic, tartaric, sulphuric, or other strong acid is previously added.

*F. of Corrosive Liquids.* As the strong acids, are filtered through powdered glass, or silicious sand, supported on pebbles in the throat of a glass funnel, or through asbestos or gun-cotton placed in the same manner. Charcoal has also been employed for the same purpose, but is not fit for some acids. Strong caustic alkaline lies are also filtered through powdered glass or sand. Weak alkaline lies may be filtered through fine calico, stretched across the mouth of a funnel. Many corrosive liquids, as solution of potassa, etc., require to be excluded from the air during *F.* The simplest apparatus that can be employed for this purpose is seen in 3, Fig. 181: *a* is a globular bottle fitted with the ground stopper, *d*, and having a perforated neck, *f*, ground to the bottle; *b* is a small tube, wrapped round with as much asbestos, linen, or calico as is required to make it fit the under neck of the bottle through which it passes. For use, the solution to be filtered is poured into the bottle, *a*, nearly as high as the top of the tube, *b*, and the stopper is replaced. The liquid then descends into *b*, and a similar quantity of air passes up the tube into *a*.

When a precipitate, or the suspended matter in a liquid, is the object of the *F.*, the filter should be of such a nature that the powder may be easily separated from it when dry, and that with the least loss possible. Linen filters are for this reason preferable for large quantities, and those of smooth bibulous paper for small ones. The powder should be washed down the sides of the filter, and collected, by means of a small stream of water, in one spot at the bottom, assisting the operation with a camel-hair pencil; and, when the whole is dry, it should be swept off the paper or cloth with a similar pencil or brush, and not removed by a knife, as is commonly done, when it can be possibly avoided. — The "first runnings" of liquid from a filter are commonly foul, and are pumped back, or returned until the fluid runs perfectly limpid and transparent, when it is "turned into" the "filtered liquor cistern," or proper receiver. In many cases the liquid does not readily become transparent by simply passing through the filter; hence has arisen the use of *filtering powders*, or substances which rapidly choke up the pores of the media in a sufficient degree to make the fluid pass clear. In the employment of these powders care should be taken that they are not in too fine a state of division, nor used in larger quantities than are absolutely necessary, as they are apt to choke up the filter, and to absorb a large quantity of the liquid. The less filtering powder used, the more rapid will be the progress of the *F.*, and the longer will be the period during which the apparatus will continue. For some liquids these substances are employed for the double purpose of decoloring, or whitening, as well as rendering them transparent. In such cases it is preferable, first, to pass the fluid through a layer of the substance in

coarse powder, from which it will "run" but slightly contaminated into the filter; or, if the powder is mixed with the whole body of the liquid, as in bleaching almond-oil, etc., to pass the mixture through some coarser medium to remove the cruder portion before allowing it to run into the filter. Another plan is, after long agitation and subsequent repose, to decant the clearer portion from the grosser sediment, and to employ separate filters for the two. Granulated animal charcoal is used according to the first method to decolor sirups, oils, etc.; and filtering powder by the second and third, to remove a portion of the color, and to clarify castor and other oils. The common plan of mixing large quantities of filtering powder with castor oil, and throwing the whole into the filter, as adopted by the druggists, is injudicious. When simple *F.* is required, it is better to use little or no powder, and to continue returning the oil that "runs" through, until, by the swelling of the fibres of the filter bags, it flows quite clear. By this plan the same filters may be used for a long period of time for many years, and will continue to work well; whilst, by the usual method, they rapidly decline in power, and soon deliver their contents slowly, and after a short time scarcely at all. — It is often of great advantage to render a filter "self-acting," or to construct it in such a way that it may "feed itself," so that it may continue full and at work without the constant attention of the operator. On the small scale, this may be readily effected on the principle of the common fountain lamp (1, Fig. 182); and on the large scale, by placing the vessel containing the unfiltered liquid on a higher level than the filter, and by having the end of the supply pipe fitted with a ball-cock, to keep the liquid in the filter constantly at the same height. — The rapidity of *F.* depends upon the porosity of the filtering medium, the extent of the filtering surface, the relative viscosity or mobility of the filtering liquid, the pressure or force by which the liquid is impelled through the pores of the filter, and the porosity and fineness of the substances it holds in suspension. The most efficient filter is produced when the first two or the first three are so graduated to the others that liquid filters rapidly, and is at the same time rendered perfectly transparent. — In the common method of *F.*, no pressure is exerted beyond that of the weight of the column of the liquid resting on the filtering medium, but in some cases additional pressure is employed. This is had recourse to for the purpose of producing a more rapid *F.*, and more especially for filtering liquids that, from their viscosity, will scarcely pass through the pores of substances sufficiently fine to remove their impurities in the ordinary way. One of the easiest means of employing pressure in *F.* is to increase the height of the column of the filtering liquid. From the peculiar properties of fluids, by which they transmit pressure in an equal degree in all directions, the vessels need not be of equal diameter throughout, but may be conveniently contracted to the size of a small pipe, as in 2, Fig. 182, which represents a small filter in this construction at work. *a* is the funnel or reservoir of foul liquid, *b*,

Fig. 182.

a small pipe conveying the liquid to the filter; *c*, *c*, a chamber, of which the upper portion, *d*, is filled with the descending liquid, and the lower portion, *e*, with the filtering media; *e* is a screw by which the bottom plate is fastened on, which plate is removed to clean out or renew the filter. For use, the cocks *k* and *l* are closed, and the liquid poured into the funnel, *a*; the cock *k* is next opened, and, in a few minutes after, the cock *l*, when an uninterrupted flow of filtered liquor will be obtained as long as any fluid remains in the funnel, *a*, and the tube, *b*. The length of the tube determines the degree of pressure. Care must be taken first to pass the foul liquid through a hair sieve, or some other strainer, to remove any substance that might choke up the pipe *b*. — Another method of employing pressure in *F.* is the withdrawal of the air from the receiving vessel, as in the vacuum filter, by which

a pressure of about 14½ lbs. to the square inch becomes exerted on the surface of the liquid by the atmosphere. The vacuum in the receiving vessel may be produced by the air-pump, by steam, or by the Bunsen or Sprengel pump. — A commoner method of applying pressure than either of those already mentioned is to condense the air over the surface of the liquid by means of a forcing-pump, or by steam. — On the small scale, pressure may be applied to *F.* by means of a siphon, whose shorter leg has its mouth blown into the shape of a bell or funnel, over which filtering paper or fine calico may be stretched. — The application of pressure to *F.* is not always advantageous, and beyond a certain limit is generally attended with inconvenience, if not with absolute disadvantage. It is found in practice that fluids under pressure take a longer period to run clear than without pressure, and that ruptures of the media more frequently take place in the former case, or with pressure, than in the latter. Great pressure is in no case advantageous.

The filters already noticed are those that act by the fluid descending through the media; but in some cases the reverse method is employed, and the liquid filters upwards, instead of downwards. These are called ascending filters, and are often preferable to those on the descending principle, because the suspended matters that require removal by filtration usually sink, and thus a portion escapes being forced into the pores of the filter. They are also more convenient when pressure is employed. The construction depends upon the same principles as the common filter, and merely requires that the feeding vessel should be higher than the upper surface of the filtering media. Oils are conveniently filtered in this way, because of their little specific gravity. By fixing (3, Fig. 182) a small filter, *d*, on this principle into the head of a cask, and pouring in water through a funnel, *c*, whose neck reaches nearly to the bottom of the cask, the oil will float up and pass the filter, leaving the sediment behind. In cold weather hot water may be employed. — In some cases the upward and downward systems of filtration are united in the same apparatus, and this plan is advantageous where the space for operating is limited. For this purpose it is merely necessary to connect the bottom of an ascending filter with the top of a descending one, or the reverse; the proper pressure being in either case applied.

**Fimble**, a light kind of hemp.

**Fin**, a membranous wing-like appendage to fish. — A trade name for a blade of whalebone. — A mark or ridge left in casting at the junction of the parts of the mole. — A tongue on the edge of a board.

**Finance**. In the 13th and 14th centuries the words *finare*, *financio*, and *financia* were employed, principally by writers in France, to denote those bargains by which the indefinite liabilities of ancient tenures were commuted by fixed sums payable to the immediate lord of the tenant. In course of time the word "finance" became nearly synonymous with the product of taxation, and the finances of a country are understood to be the ways and means by which the expenditure of a government are met. The word is also commonly applied to the art of managing money-matters, the person who professes this art being called a *financier*. See MONEY, NATIONAL DEBT, etc.

**Findings**, the wax, thread, and tools which a journeyman shoemaker has to supply himself with in his work.

**Finding-Store**, a store where shoemakers' tools, trimmings, etc. are vended, and which, in England, is termed grindery-warehouse.

**Fine-Arts**, a term applied to painting, sculpture, architecture, and other arts requiring taste, skill, and judgment in the execution, and in which the artist seeks chiefly to give pleasure by the immediate impression produced on the mind by his work; these arts being thus distinguished from arts which are designed to answer some practical purpose, and so have been termed *useful*.

**Fine-Drawing**, a finishing process with cloth, in which it is subject to a strong light while all faulty parts or breaks in the fabric are closed by sound yarn introduced by a needle. — *E. H. Knight*.

**Fineness**, the proportion of pure metal in an alloy, expressed in 1,000 parts; as the *F.* of U.

States gold coin is 900, the other 100 being alloy. See ASSAY.

**Fineer** [Scotch], to veneer.

**Finery**, showy articles of dress; jewels, trinkets, etc. — The furnace in which cast-iron is converted into malleable iron.

**Finesse** [Fr.] may be defined simply as a peculiar aptitude of discovering in any business the best means of attaining the object in view; or as the power of embracing in one comprehensive glance the various interests of any subject, together with ingenuity to devise and tact to carry out the plan best calculated to obtain success.

**Fine-Stilling**, the distillation of spirit from molasses or other preparations of sugar.

**Fine-Stuff**, the second coat of plaster for the walls of a room, composed of finely sifted lime and sand mixed with hair; the first coat is of a coarser material.

**Finger**, an ancient measure, the fourth part of the palm, or hand, nearly an inch. — A measure of domestic use in the U. States, of about 4½ inches, or ¼ of a yard.

**Finger-Board**, the neck of a violin, banjo, guitar, etc., on which the strings are pressed by the fingers in playing.

**Finger-Glass**, a colored or plain glass vessel to hold water for rinsing the fingers after dessert.

**Fingerin**, worsted spun in Scotland, from combed wool, on a small wheel.

**Finger-Plate**, an ornamental piece of metal or porcelain fixed on the edge of a door, to keep off finger-marks from the paint-work.

**Fingroms**, woollen cloth made of combed wool.

**Fining**, the process of refining, purifying, or clarifying turbid liquors. The simplest mode of *F.* is by passing the liquor through a porous substance that retains the solids and allows the clear liquid to pass through (see FILTER); but this method is only applicable to particles mechanically suspended in a limpid liquid. When the liquid contains mucilaginous or other matter, that readily clogs the filter, some other means of *F.* must be used. Such is the case with all malt liquors, and most wines when turbid. When in good condition, these do not usually require *F.*, as the suspended matter agglomerates, and sinks to the bottom shortly after the fermentation is completed. When this does not take place, some means of promoting such action are usually adopted. One of the simplest is to add soluble albumen, such as white of egg, to a portion of the liquid, and, after beating it well in this, to add the mixture, and stir it into the whole of the liquid. Upon the application of heat, the albumen coagulates and contracts from its diffusion into a scum, enveloping and drawing together the suspended matter. The scum is then easily removed. This method is adopted for sirups and other liquids that may be heated without mischief. In making clear soups, the albumen of the meat performs this function. As alcohol coagulates albumen, it may be used for *F.* wines and cordials without the application of heat. It is generally used for red wines. Malt liquors are usually fined by means of gelatine, either isinglass or cheaper substitutes being used. One pound of isinglass is soaked in three or four pints of water, or sour beer, then more sour liquor added as the isinglass swells, until it amounts to about a gallon. The jelly thus formed is next dissolved in seven or eight gallons of the liquor to be fined. This solution, having the consistence of a sirup, is called *brewers' finings*, and about a pint to a pint and a

half is added to a barrel of ale or porter, or to a hoghead of cider or wine. The action of this depends upon the combination of the gelatine with the astringent matter (*tannic acid*) of the liquor, forming thereby an insoluble solid, which sinks to the bottom, and carries with it, like the coagulating albumen, the suspended matter; but as the flavor of malt liquors partly depends upon the astringents they contain, the *F.* affects the flavor; the astringents also help to preserve the liquor, and hence their removal is in this respect disadvantageous. Malt liquors thus fined do not "stand well on draught." The use of gelatine for *F.* red wines is objectionable, as in most of these the astringent flavor is an esteemed quality, and therefore albumen is preferred. — There are other methods of *F.*, but all of them are more or less objectionable. Liquors that are unusually difficult to fine are called *stubborn* by coopers and cellarmen.

**Fining-Pot**, a vessel in which metals are refined.

**Finish**, the peculiar style and effect produced on the surface by the last touches.

**Finisher**, one who completes work for sale, as in watch-making, the boot and shoe trade, etc.

**Fire**. See **PINE**.

**Fire**, the effect of combustion; also a burning, a conflagration. See **COMBUSTION**, **HEAT**, **LIGHT**, **INSURANCE (FIRE)**, etc.

**Insurance**. — (What is fire?) The necessity for defining exactly what is loss by fire within the meaning of the word in insurance policies has frequently arisen. It is clear that damage may arise as a consequence of fire which is not precisely and directly a damage by fire. Thus, for instance, lightning is fire, and is capable of burning, but it frequently destroys or injures by the force of the electric current, as when stone or brick work is dislodged on being "struck," as it is termed. Again, great destruction is often caused by the explosion of gas, without any combustion of the destroyed materials. As a concession and act of grace all the offices now admit claims from gas explosions, but not from explosions generally. The simple rule for determining the question of what is fire within the meaning of a fire policy, is to decide whether there has been *actual ignition* of what is insured. Difficult cases may, and do occasionally arise, but as a general rule the definition of damage by fire as damage by actual ignition will be decisive.

**Fire-Alarm Telegraph**, a system of telegraphy of American invention, patented in 1857 by Farmer and Channing, and used in all the large cities of the U. States for giving notice of fire. It comprises a series of signal-boxes at suitable intervals over the city, connected by telegraph wire, with the central office and all the stations of the fire department. They are small boxes about a foot square, numbered in order and placed conspicuously on telegraph poles, or on the side of a building at corners of streets. Inside of each is a simple clock-work, which is set in motion by the pulling of a handle, and which records at the central office the number of the box.

**Fire Annihilator**, invented by Phillips in 1849. This is essentially a gaseous fire-engine, which at any moment can be made to discharge a stream of mixed gases and vapors having the power of checking combustion. When first introduced it was generally regarded as a most important invention, but it has not proved an effective substitute for the common water engine. For extinguishing fires on board ship and in close apartments it is undoubtedly well adapted, but

as a street-engine it is comparatively useless, owing to the unmanageable nature of its fire-annihilating vapors. The composition with which the apparatus is charged is a mixture of dried ferrocyanide of potassium, sugar, and chlorate of potassa. It is set in action by a blow on a glass vessel containing oil of vitriol, which, being fractured, permits the acid to flow over the "charge," when the anti-combustion gas is liberated, and rushes forth with great impetuosity. See **FIRE-EXTINGUISHER**.

**Fire-Arms**, a general name for all kinds of arms or offensive weapons from which destructive missiles are discharged. See **CANNON**, **GUN**, **REVOLVER**, etc.

**Fire Association of Philadelphia**, a fire-insurance Co., located in Philadelphia, Pa., and organized in 1820. *Statement*, Jan. 1879: Cap. stock paid up in cash, \$500,000; net surplus, \$422,326.19; risks in force, \$169,070,653; premiums, \$2,729,887.86; premiums received since the organization of the Co., \$8,826,925; losses paid, \$3,615,199.95; cash dividends paid to stockholders, \$1,579,792.

**Fire-Ball**, a grenade filled with combustibles, to be thrown among enemies for the purpose of setting fire to, or merely illuminating, some work against hostile operations are directed.

**Fire-Balloon**, a balloon sent up at night with fireworks, which ignite at a regulated height.

**Fire-Bars**, wedge-shaped iron bars fitted to the fire-box of a locomotive boiler with the thick side uppermost, to support the fire; the ends rest on a frame; they are inclined inward, with an air-space between each, to promote combustion, and are joined at one end, and supported by a rod at the other, so that, the rod being withdrawn, the bars fall and the fire-box is emptied.

**Fire-Basket**, an iron receptacle for holding a small portable grate with coals, etc., for a bedroom.

**Fire-Box**, the box (usually made of copper) into which the fire of a locomotive boiler is placed. The outside is of iron, separated from the copper fire-box by a space of about 3 inches all around for water. — *Fire-box door*, the door opening into the fire-box, facing the locomotive tender, by which coke is supplied to the fire. — *Fire-box partition*. In large fire-boxes a division is made in the box, into which the water is admitted; this division is about the height of the fire-box door, and divides the fire into two parts in a locomotive-engine, thereby increasing the heating surface of the fire-box. — *Fire-box stays*, deep, strong iron stays bolted to the top of the copper fire-box, to enable it to resist the pressure of the steam; round copper or iron stays are also used to connect the outside shell to the inside box, in the proportion of about one stay to every 4 square inches of flat surface.

**Fire-Brick**. See **BRICK**.

**Fire-Brush**, a hair sweeping-brush for the hearth of a room.

**Fire-Bucket**, a light canvas or leather pail, chiefly used on shipboard, to carry water for putting out fires.

**Fire-Clay Bricks and Retorts**. Fire-clays, used in the manufacture of fire-bricks, may be defined as a native combination of hydrated silicates of alumina mechanically associated with silica and alumina in various states of subdivision, and sufficiently free from silicates of the alkalis and from iron and lime to resist vitrification. The best fire clays are characterized by a preponderance of alumina, tenacity of texture,

contractibility in the kiln, and an absence of iron and the alkalis, etc., which tend to vitrification. Tenacity of texture in a fire-brick material is a mechanical condition which assists vitrification, a coarse open body being more refractory than a coarse homogeneous brick of similar chemical composition. A well-manufactured brick should be of a pale cream or buff color, uniform throughout its mass, and burnt to the full extent of its contractility. A properly burnt brick, uniform in color throughout its mass, can only be obtained by slow, progressive firing; a broken brick that has been too quickly burnt, though pale on the surface, presents a darker central patch, and concentric rings of various shades of color, due mainly to the different states of oxidation of the iron, and partly to the presence of unconsumed carbonaceous matter; but the chemistry of this color-variegation is not clearly understood.

It is beyond the scope of this article to enter into the details of the fire-brick manufacture, which in its main features resembles the manufacture of building-bricks, except that fire-bricks are rarely if ever burnt in clamps. Fire-bricks are now manufactured to perfection in this country. In the large establishment founded in New York by Mr. Adam Weber, under the name of "Manhattan Works," and which may be given as a model of the kind, properly constructed ovens on the "down draught" principle are employed, which insure greater regularity in the burning than in the old form of kiln; and the partially moist ground clay dust is compressed into bricks in iron moulds by steam-power, by which process more shapely bricks are produced than by plastic moulding, and their perfectly true flat sides enables a minimum of jointing material to be employed, a circumstance of importance in the stability of fire-brick masonry, as thick fire-clay jointing contracts in the firing, tending to shatter the structure. In addition to the fire-bricks, blocks, and tiles, for furnaces, rolling-mills, foundries, lime-kilns, glass-works, etc., Mr. Adam Weber manufactures on a large scale the celebrated enamelled clay retorts for gas-works, which, bearing a higher heat than those of iron, are becoming generally adopted. See RETORT.

**Fire-Chamber**, the chamber at the end of the puddling furnace, whence the flame passes to the reverberating chamber where the charge is placed.

**Fire-Cock**, a plug for obtaining water from the main pipes in a street to extinguish fires.

**Fire-Cracker**, a kind of small Chinese firework, containing gunpowder tightly confined in thick rolls of clay and paper, exploding with a loud, sharp noise, and largely used throughout the

**Fire-Damp**. In most coal-mines the coal itself is subject to chemical changes which cause it to

Fig. 183. — DAVY'S SAFETY-LAMP.

give forth large quantities of carburetted hydrogen gas, known to the miners as *F.-D.* Sometimes, when a hole for blasting is bored, a jet of this terrible gas will immediately stream forth from it. There are many cavities in the coal quite full of gas; and when one of these is laid open by the miner's pick, the gas rushes out with a current called a *blower*, continuing in action for even months together. Long pent-up reservoirs of such gas, set free after an unknown period of accumulation, are the most dangerous sources of explosion. If small coal is set on fire by the explosion, there is still a further danger from *choke-damp*, or suffocating carbonic acid. When sad experience showed how dangerous an open candle is in a coal-mine filled with *F.-D.* or explosive gases, ingenious men sought for some means of averting the danger. At one time a sort

of continuous flint-and-steel apparatus was adopted, to keep up a succession of sparks that would in some degree light up the mine; but this has been superseded by the beautiful *safety-lamp* (Fig. 183). The invention was chiefly due to Sir Humphry Davy; but the practical development to George Stephenson and Dr. Clanny, followed by many other ingenious men. The principle of action is, that the inflammable gas of a coal-mine, when kindled into a flame, will not pass through the meshes of a very fine iron wire-gauze; the gas itself will pass when cold or non-ignited, but not as a heated flame. An oil-lamp is placed within a gauze cylinder, having no openings except the meshes. Air easily enters to feed the flame. *F.-D.* also easily enters, kindles, and fills the whole interior of the cage or cylinder with a blue flame; but this flame cannot get out to kindle the great body of gas in the mine. The blue flame in the lamp is a warning to the miner that the air around him is very foul and dangerous. Any defect in the lamp, or any carelessness in his mode of using it, may lead to instant explosion, followed by death or terrible mutilation. The light is sometimes so dim as to tempt the miner to obtain an increase by opening the gauze door of the lamp, — a perilous practice, to avert which numerous forms of new lamps have been invented by Waring, Robinson, Ogden, Muesler, and other inventors.

**Fire-Engine**, an hydraulic machine or force-pump, for raising water to a great height to extinguish conflagrations. The *hand-worked engine*, which is still to a great extent in use in England, France, and other European countries, consists essentially (Fig. 184) of a pair of vertical single-acting

Fig. 184. — HAND-WORKED FIRE-ENGINE.

U. States on Independence Day, the imports from China for the year 1878 amounting to \$145,054. This public nuisance has been of late prohibited — ineffectually to this day — by the legislature of New York and other States.

*Imp. duty*, per box of 40 packs, not over 80 in each pack, \$1 per box; and in the same proportion for greater or less numbers.

force-pumps, worked by means of long brakes, that enable many men to assist in using them. The pumps discharge into one common reservoir, the upper part of which, *c*, contains air, that by its elasticity causes the water to flow in a uniform stream through the discharge-pipe. From this pipe the water is conducted any desired distance through the leathern hose, and discharged through a strong tapering metallic pipe, that is held in the hand to direct the stream upon the fire. A suction-pipe is attached to the lower end of the pump when necessary, but it is not required when the stream of water introduced to supply the pumps has sufficient head. The whole machine is placed upon a carriage expressly constructed for it, and furnished with such implements as are likely to be wanted at a fire. In working the *F. E.*, ropes are sometimes made fast to the brakes, and, pass-

these first engines was their great weight, and the length of time required for raising steam. The city of Cincinnati first demonstrated the practicability of this application of steam, so as to completely supersede the hand engines in the great cities. The first of these engines was built by the brothers Latta and Mr. Abel Shawk, in 1853. This machine was very large and powerful, — but very heavy, — weighing upwards of 12 tons, and requiring 4 horses to haul it. This machine, with some few others, was constructed so as to apply the steam to the wheels to aid in propelling it through the streets; but this idea was soon abandoned. The controlling feature of the Cincinnati engine is the boiler. It has a square fire-box open at the top, and the upper portion of the furnace is occupied by a continuous coil of water-tubes, opening above into the steam-chamber, and the lower end

Fig. 185. — STEAM FIRE-ENGINE.

ing through blocks at the bottom of the carriage, are hauled upon by a number of men with each down stroke. Some engines have the pumps arranged horizontally, and men sit on the top and work as in rowing a boat. It is considered a good performance for a first class hand engine to throw a stream through 100 feet of hose to a height of 100 feet. The *steam F. E.* (Fig. 185) which is now in use in almost all cities of the U. States is essentially a pair of single acting suction and force pumps driven by steam power. It is hauled by two horses, and is self propelled. The first attempt to apply steam to the working of *F. E.* was made by Capt. Ericsson, in London, in 1830. After the great fire in New York, in 1835, premiums were offered for plans of *steam F. E.*, and in 1841 one was built from plans of Mr. Hodges, and brought into service at fires with good effect. The great difficulties in the way of the successful use of

connected with a force-pump outside, by means of which water is driven through the whole length of the coil. By this arrangement the steam can be raised and the engine be in working order in from 3 to 4 minutes. The Cincinnati engine has been excelled nowhere, and has been copied into the principal cities of the world. As successively improved, it gives the following average record: Time of raising steam, three minutes and forty seconds from the time the torch is applied until water is thrown from the nozzle; size of nozzle, 1½ inches; distance thrown, 310 feet, measuring from the end of the nozzle to the place where solid water fell; size of steam cylinder, 10 inches bore, 24 inches stroke; pumps, 6 inches bore, 24 inches stroke; double engine cranks at right angles; large air-vessels, connected together; length of hose, 100 feet; steam, 100 pounds to the square inch; pressure on water cylinder, 240 pounds to

the square inch; speed of engine, 110 revolutions; 220 strokes of pumps; grate surface, 16 feet; heating surface, 560 feet. — Steam *F.-E.* are principally manufactured in Philadelphia, Boston, Cincinnati, and Manchester (New Hampshire).

*Chemical F.-E.*, acting on the principle of the *Fire-Extinguisher* (q. v.), have been lately introduced, and are of several forms and sizes, among which Fig. 187 represents the Babcock engine. The size most used consists essentially of two cylindrical copper or steel tanks, each holding 80 gallons of water. The charge for each tank is 28 lbs. bicarbonate of soda and 14 lbs. sulphuric acid. The soda is dissolved in the water, and the acid is held in a leaden jar within the tank, which is securely closed. At the moment of using the sulphuric acid is mixed with the water, and instantly combining with the soda, causes carbonic acid to be given off with a pressure of 140 lbs. on the sq. inch. The tanks are used independently and charged separately, so that a continuous stream of water, usually  $\frac{1}{4}$  inch jet, may be maintained. The whole apparatus, charged, and carrying four men, weighs about 3,600 lbs., and is drawn by two horses. The hose is rarely carried upon the engine; it is usually on a separate carriage drawn by one horse. Chemical engines, it is said, can be used with advantage and effect wherever there is a scarcity of water; and still more, where there is an abundance of water, by putting out a fire before the steamers can get to work, and before it becomes large and destructive.

**Fire-Escape**, a contrivance to facilitate exit from a burning building. The apparatus suggested, and more or less put into operation, to assist in the escape of persons from burning houses, has been exceedingly varied. Straps or belts, sustaining a seat on which the person may be lowered; telescope ladders, capable of being drawn out and pushed in; jointed ladders, connected like the pieces of the chimney-sweeping apparatus; rope-ladders, that may either be lowered from above or raised from below; a pole, with cleats or ledges that will convert it into a kind of ladder; a chair, so placed as to be lowered by ropes from a window; a pole supporting a pulley, by which a rope can be hauled up and down a bag, large enough to contain a man, and arranged so as to be lowered down a ladder; the lazy-tongs (Fig. 186); a canvas shoot, extending from the top to the bottom of a ladder, down which a person might slide, — these are types of the several kinds of fire-escape which have been practically tried.

Fig. 186. — FIRE-ESCAPE.

**Fire-Extinguisher.** The portable chemical extinguisher, now in extensive use in factories, warehouses, and public buildings, is chiefly effective to put out any fire in its earliest stages. There are about 60 American patents for various forms of this apparatus, most of which are contrived on this principle, that fire being supported by oxygen, carbonic acid gas, which is much heavier than air,

must shut off the supply of oxygen, and immediately smother fire.

In the extinguisher represented in Fig. 187, the glass bottle, A, holds a charge of sulphuric acid, and is kept in its position by the cup B and the cap C. The exit pipe extends, inside, to the bottom of the machine. To prepare the extinguisher for use, the extinguisher is filled to within 3 inches of the top with water in which bicarbonate of soda has been dissolved. The bottle of acid, with the cap over the neck, is placed into the cup, and the head being inserted in the extinguisher is screwed down hard and tight. The machine is then charged, and may remain in this condition for any length of time, always ready for immediate use. In case of fire, the handle on top is to be screwed down until the shoulders meet, thus breaking the bottle, and discharging the acid into the carbonated water. Instantaneous chemical action takes place, and the compressibility of the carbonic acid generated affords the power which projects the liquid. The working pressure varies from 70 to 120 lbs. per sq. inch, according to the temperature of the surrounding atmosphere; and the projectile range of the jet is from 40 to 50 feet.

Fig. 187. — FIRE-EXTINGUISHER.

**Fire-Guard**, a wire frame to be hung before a fire-grate to prevent sparks and burning coals, etc., flying out and endangering furniture.

**Fire-Hook**, a large hook used by firemen for pulling down walls, etc., during the conflagration of a building.

**Fire-Hydrant**, or **Fire-Plug**, is a large kind of hydrant, having a larger service-pipe from the main, and used for connection of hose for street washing, or in case of fire.

In Fig. 188 is represented a sectional elevation of the improved fire-hydrant, originally introduced by Mr. Sam'l P. Ayres, and now owned and manufactured in New York by Mr. John McLeau, which is largely used in most of our principal cities.

Fire-Hydrant.

Stopcock.

Fig. 188. — AYER'S FIRE-HYDRANT AND STOPCOCK.

A is the stock or case below the pavement, which is enlarged to such an extent at its lower end, B, that the area around the valve, C, is fully equal to the capacity of the nozzle, D; E is a waste-valve, perfectly automatic in its operation. When the valve is open, the pressure of the water acting on the lower side of the small valve in E closes the opening of the valve, and

as soon as the main valve, C, is closed, the pressure being removed from the bottom of the valve, the weight, F, causes the valve to drop from its seat, and permits the water in the stock to escape, thus preventing any liability to freeze. See HYDRANT and STOPCOCK.

**Fire-Insurance.** See INSURANCE (FIRE).

**Fire-Irons,** the utensils for a fire-grate, — tongs, poker, and shovel.

**Firelock,** a musket or other small arm, having a lock for igniting the charge by means of a flint and steel.

**Fireman,** a member of a fire-brigade or company. — The feeder of a furnace, marine or locomotive engine.

**Fireman's Trust,** a fire-insurance Co., located in Brooklyn, N. Y., organized in 1859. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$150,000; net surplus, \$80,318.07; risks in force, \$10,583,196; premiums, \$65,959.61; premiums received since the organization of the Co., \$1,092,207.81; losses paid, \$423,034.92; cash dividends paid to stockholders, \$241,500.

**Firemens,** a fire-insurance Co., located in Baltimore, Md., and organized in 1825. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$378,000; net surplus, \$112,490.90; risks in force, \$18,694,350; premiums, \$87,642.48; premiums received since the organization of the Co., \$4,708,158.92; losses paid, \$2,193,342.60; cash dividends paid to stockholders, \$5,519,180.24.

**Firemens,** a fire-insurance Co., located in Dayton, O., organized in 1856. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$250,000; net surplus, \$63,420.28; risks in force, \$12,904,696; premiums, \$140,029.36; premiums received since the organization of the Co., \$1,191,027.06; losses paid, \$410,869; cash dividends paid to stockholders, \$339,892.40.

**Firemens,** a fire-insurance Co., located in Newark, N. J., organized in 1855. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$400,000; net surplus, \$580,518.97; risks in force, \$27,239,754; premiums, \$214,383.86; premiums received since the organization of the Co., \$2,538,973.92; losses paid, \$702,807.16; cash dividends paid to stockholders, \$390,500.

**Firemens,** a fire-insurance Co., located in New York City, organized in 1825. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$204,000; net surplus, \$85,827.00; risks in force, \$9,709,205; premiums, \$47,520.57; premiums received since the organization of the Co., \$4,019,275.28; losses paid, \$2,520,555.02; cash dividends paid to stockholders, \$1,301,578.17.

**Firemen's Fund,** a fire-insurance Co., located in San Francisco, Cal., organized in 1863. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$300,000; net surplus, \$124,717.75; risks in force, \$34,510,313; premiums, \$453,880.75; premiums received since the organization of the Co., \$5,534,800; losses paid, \$3,630,435.00; cash dividends paid to stockholders, \$784,000.

**Fireplace,** the place within a chimney piece where fuel is burnt. The several parts of the chimney-piece, shown in Fig. 189, are: (1) the slab, (2) the hearth, (3) the jamb, (4) the fireplace, (5) the mantel-piece, (6) the throat, (7) the gathering, (8) the funnel,

FIG. 189. — CHIMNEY-PIECE.

(9) the flue, (10) the mantel, (11) the back, (12) the grate, (13) the breast, (14) the damper.

**Fire-Plug,** a plug for drawing water from a pipe or hydrant for extinguishing a fire.

**Fire-Proof,** a vault, safe, or building so constructed as to be secure from the ravaging effects of fire, should it break out. If accidental fires could be prevented instead of extinguished, there would of course be a great improvement; but, so long as there are combustible materials and careless people, this is hopeless. Fire-proof construction is now carefully attended to in large buildings. Brick and stone walls; iron steps, lintels, ties, doors, and partitions; floors of concrete or iron, — in short, the absence as much as possible of timber, — such is the mode resorted to, and in many cases with success. But there are even here drawbacks, so far as iron is concerned: this metal conducts heat more rapidly than wood, while cast iron cracks and gives way. The management of the draught, too, in passages and staircases, has much to do with the travelling of flame and hot air from one floor or room to another. In fact, the best mode of fire-proof construction is still a problem. See INCOMBUSTIBLE FABRICS, SAFE, etc.

**Fire-Screen,** a wire guard or protection against fire. See FIRE-GUARD.

**Fire-Set,** the metal articles, poker, shovel, and tongs, for a grate; usually made of steel or wrought-iron.

**Fire-Ship,** a vessel filled with combustibles sent into an enemy's fleet to injure it.

**Fire-Shovel,** the coal-shovel for a fireplace.

**Fire-Stop,** the fire-bridge at the back of a furnace; so called because it prevents coals being pushed over.

**Fire-Wood,** small bundles of wood, in different shapes, prepared by machinery, for lighting fires; the sale of fire-wood has become a very important and extensive trade in New York and other populous cities.

**Fireworks.** See PYROTECHNY.

**Firkin,** an English measure of capacity, the fourth of a barrel, now disused; but the name is still applied to a cask containing nominally 9 gallons of beer or 8 of ale, but truly only  $7\frac{1}{2}$  imperial gallons. A firkin of soap is 64 lbs.; of butter, usually considered, 56 lbs.; but Irish butter-firkins weigh nearly  $\frac{1}{4}$  of a cwt. gross, the cask weighing about 14 lbs.

**Firiot,** a Scotch dry measure, the fourth part of the boll; the Linlithgow wheat firiot is 2,211 cubic inches, very nearly equal to the imperial bushel, but the barley firiot contains 31 standard pints only, = 1,074.420 cubic inches.

**Firm,** the persons composing a copartnership taken collectively; a house of business; the abbreviated title under which a trade is conducted by a number of partners, as the firm of A. T. Stewart & Co. Under the laws of the State of New York no person may transact business in the name of a partner not interested in his firm, and where the designation "and Company" or "& Co." is used, it shall represent an actual partner or partners. But the business of two or more persons may be conducted under the firm name of but one person; or without the use of the name of either of the parties composing the firm, as the firm of James G. King's Sons. — T. McElvath.

**Firman,** an edict or legal authority from the Turkish government.

**Firmer-Chisel,** a chisel shorter than a paring-chisel, lighter than a framing chisel, thin in proportion to its width, having a tang to enter the handle, and of which there are about twelve widths.

**First Coat**, in plastering, the *laying* the plaster on the laths, or the *rendering*, as it is called, on brick when only two coats are used. When three coats are used, it is called *pricking up* when upon laths, and *roughing in* when upon brick.

**First-Hand**, obtained direct from the maker, shipper, or wholesale dealer.

**First-Mate**, the chief officer of a merchant vessel; the next in rank to the captain.

**First National Fire-Insurance Co.**, located in Worcester, Mass., and organized in 1868. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$200,000; net surplus, \$14,663.15; risks in force, \$9,392,165; premiums, \$138,573.48. Premiums received since the organization of the Co., \$1,229,309.03; losses paid, \$757,614.98; cash dividends paid to stockholders, \$74,000.

**First-Rate**, excellent; of superior quality. — One of the largest ships of war, a vessel carrying 100 or more guns.

**Fisc**, a law term, applied in France and other countries of Europe to the public treasury, which is entitled to all fines, forfeited goods, goods without an owner, etc.; whence our term *confiscation*.

**Fiscal**, pertaining to the public treasury, or to the revenues of a state; as, *fiscal measure*. — The *fiscal year* of the U. States formerly ended on 31st December, and, up to the year 1843, on 30th September; but Congress enacted, August 26, 1842, "That on and after the first day of July, in the year of our Lord 1843, the fiscal year of the treasury of the U. States, in all matters of accounts, receipts, expenditures, estimates, and appropriations, shall commence on the first day of July in each year; and the reports and estimates required to be prepared and laid before Congress at the commencement of each session by the Secretary of the Treasury, in obedience to the acts of Congress, of the 2d of September, 1789, and of May 10, 1800, shall be a report and estimate for each fiscal year, commencing as aforesaid, and terminating on the 30th day of June, in the succeeding calendar year."

**Fish** [Dutch, *Visschen*; Fr. *poissons*; Ger. *Fische*; It. *pesci*; Port. *peixes*; Sp. *pescados*. The plural of the English word is *fishes*, but the singular is often used for fishes in general, or the whole race], a general name for marine swimming animals, which form the lowest class of the *Vertebrata*, and in the capture and sale of which a large trade is carried on. In the variety of their genera and species fishes are second only to the insects, whilst in prolificness and number they probably exceed all other animated beings that reach a size equal to that of even the smallest member of their prodigious race. Besides their value to man as food, they furnish him with oil, isinglass, and various other articles of utility and luxury, and provide, either directly or indirectly, an inexhaustible supply of manure for the fertilization of his fields. As food, fish are undoubtedly wholesome and nutritious, although less so than the flesh of animals or the grains of the cereals. Of all the various substances used as aliments by man, fish are, however, the most liable to run into a state of putrefaction, and should therefore be only eaten when perfectly fresh, or, if not recently taken, then only when their perfect preservation has been insured by any of the ordinary methods employed for the purpose. Those that are the whitest and most flaky when cooked, as cod, flounders, haddock, hake, soles, turbot, whiting, etc., are the most easily digested; and those abounding in oily matter, as eels, herrings, mackerel, salmon, etc., are most nutritious, though the most likely to

offend the stomach. Salt-water fish have been said to be more wholesome than river fish, but without sufficient reason. Salted fish are hard of digestion, unless when carefully cooked and well masticated. Skin diseases are said to be more common among those who live continually on fish than among those who abstain from it; but this probably arises from their use being unaccompanied by a proper quantity of fresh vegetables or fruit, both of which are scarcer on the sea-coast than further inland. As one of the components of a mixed diet, the value of fish is indisputable. Acid sauces and pickles are the proper additions to fish, from their power of retarding the progress of putrefaction, and of correcting the relaxing tendency of large quantities of oil and butter. See SEA-FISHERIES, and PISCICULTURE.

*Imp. duty*: All foreign-caught fish, not in barrels or half-barrels, and not otherwise provided for, 50 cts. per 100 lbs. — All fresh fish for immediate consumption, free. — All fish in oil, not otherwise provided for, 30 per cent. — Fish of all kinds, the product of the sea-fisheries of Newfoundland (fish in bond excepted), free. — All pickled fish, in barrels, excepting herrings, mackerel, and salmon, \$1.50 per bbl. — Codfish, dried, 4 ct. per lb. — Fish for bait, free. — Herrings, pickled or salted, \$1 per bbl., or 50 cts. per 100 lbs. — Living fish, 20 per cent. — Mackerel, \$2 per bbl. — Fish in kits, 1 ct. per lb. — Fish of American fisheries, free. — Prepared fish, 35 per cent. — Fish preserved in oil, not otherwise provided for, 30 per cent. — Salmon, pickled, \$3 per bbl.; preserved, 30 per cent.

In the U. States, a barrel of fish is 200 lbs. net, exclusive of salt or brine.

**Fish**, a sea-term for strengthening a weakened spar by fastening other pieces on. — To raise the flukes of an anchor on the gunwale, or vessel's side. — To catch fish by net, or by hook and line.

**Fish-Bar**, the splice-bar which breaks the joint of two meeting objects, as of railroads, rails, or scarfed timber.

**Fish-Beam**, a beam with a bulging belly.

**Fish-Block**, the block of the fish-tackle for raising the anchor.

**Fish-Carle**, a Scotch fisherman.

**Fish-Carver**, a silver knife for helping fish at a dinner-table.

**Fish-Curer**, a salter and smoker of fish.

**Fish-Davit**, in ship-building, a spar or small crane projecting from the bow of a ship for the suspension of the tackle, called the *fish-fall*, used in hauling up the arms of the anchor in getting it aboard. The fish-davit is such a distance abaft the *cathead* as the length of the anchor may require, and is used to lift the fluke of the anchor to the bill-board; a roller keeps the fluke from bruising the vessel's side.

**Fisher**, a name for the *Mustela canadensis*; the skin is principally used for trimmings and linings, the fur being long, fine, and lustrous, but not so valuable as the sable. The tail is extensively used by the Jews.

**Fisheries**. See SEA-FISHERIES and WHALE-FISHERY.

**Fisherman**, one who follows the business of catching fish for sale.

**Fisherman's-Bend**, a sailor's knot, used in binding halyards to a studding-sail yard. Two turns are taken round the spar, the end passed between them and the spar, and half hitched around the standing part.

**Fish-Fag**, a fisherman.

**Fish-Flake**, a structure on which fish are spread to be air and sun dried.

**Fish-Gig**, a kind of harpoon or spear, with several barbed prongs, attached to a line, used for striking fish at sea.

**Fish-Glue**. See ISINGLASS.

**Fish-Hook** [Fr. *hameçon*; Ger. *Fischungel*], a barbed instrument of various size and form, for catching fish (Fig. 190). They were formerly largely imported from Redditch, in Worcestershire, England; but they are now manufactured in New York, Brooklyn, and other places in the U. States. The barbs of the American fish-hooks, being better formed than those of the English, are pretty largely exported. *Imp. duty*, 30 per cent.

They are constructed with simple tools, but require great manual dexterity in the workmen. The iron wire of which they are made should be of the best quality, smooth and sound. A bundle of such wire is cut in lengths, either by shears or by laying it down upon an angular wedge of hard steel fixed horizontally in a block or anvil, and striking off the proper lengths by the blows of a hammer. In fashioning the *barbs* of the hooks, the straight piece of wire is laid down in the groove of an iron block made on purpose, and is dexterously struck by the chisel in a slanting direction, across so much of the wire as may be deemed necessary. A sharp-pointed little wedge is thus formed, whose base graduates into the substance of the metal. The end of the wire where the line is to be attached is now flattened or screw-tapped; the other end is sharp-pointed, and the proper twisted curvature is given. The soft iron hooks are next case-hardened, to give them the steady stiffness and elasticity, by imbedding them in animal charcoal contained in an earthen or iron box; after which they are brightened by heating and agitating them with bran, and finally tempered by exposure to a regulated temperature upon a hot iron plate. Hooks for salt-water fishing are frequently tinned, to prevent them wearing rapidly away in rust.

**Fishing**, the art or practice of taking fish. — Used or employed in fishing, or by fishermen; as a *fishing-rod*, a *fishing-boat*, etc. — In machinery, uniting by clamping between two short pieces which cover the joint. — On board ship, lifting the anchor-fluke on to and over the gunwale.

**Fishing-Boat**, a small decked or undecked boat in which the pursuit of fish is carried on.

**Fishing-Line**, small cord of different sizes, with, in some instances, gut or chain attached, to which a hook is appended, for river or sea fishing (*d.* Fig. 191).

**Fishing-line Reel**, a little winch, usually attached to a fishing-rod, and upon which the line is wound.

**Fishing-Net**. See **NET**.

**Fishing-Rod**, a rod for fishing (Fig. 191), usually made of bamboo lengths, fastened together by telescopic or screw couplings.

**Fishing-Smack**, a sloop having a water-chamber in the hold to keep fish alive.

**Fishing-Tackle**, the various appliances for angling and fishing, including fish-hooks, rods, reels, reel-lines, casting-lines, gut-lines, baits, artificial flies, salmon flies, baskets, bags, fly-boxes, floats,

nets, harpoons, spears, forks, lesters, stakes, weirs, etc. In the U. States the fishing-tackle business is very extensive, and is chiefly centred and conducted in Fulton Street, New York.

**Fishing-Tube**, in microscopy, an open-ended glass tube for selecting a microscopic object in a

Fig. 190. — Fish-Hooks.

fluid. The tube is closed at the upper end by the finger until the lower end is close to the object. The finger being raised, the water rushes in, carrying the object with it. — *E. H. Knight*.

**Fish-Kettle**, an oblong metal boiler, for cooking fish in.

**Fish-Knife**, a broad flat silver or plated knife for serving fish with at table.

**Fishmaw**, the sound of a fish. In the eastern seas a large trade is carried on in fishmaws, which are sent to China and used as glue, etc.

**Fishmonger**, a general dealer in fish.

**Fish-Oil**, a general name for the oil obtained from various marine animals and fishes, — from the livers of sharks in warm regions; from cod, ray, pilchards, and other large and small fish; from the seal, sea-elephant, dugong, etc. The leading fish-oil of commerce, however, is whale-oil.

**Fish-Plate**, a small plate of wrought-iron used to secure together the ends of the iron rails on railroads, to hold them strictly in line, avoiding deflection or sagging.

**Fish-Pot**, a wicker basket or enclosure sunk with a cork float attached, for catching crabs, lobsters, etc.

**Fish-Salesman**, one who receives consignments of fish for sale to retail dealers.

**Fish-Sauces**, anchovy, soy, and other condiments, used as flavorings for cooked fish.

**Fish-Scales**, the coating of some kinds of fish; the hard scales are now frequently used for making brooches, bracelets, and ornamental flowers, etc. The scales of the bleak are dissolved to coat the inner surface of glass beads or artificial pearls.

**Fish-Slice**, a silver perforated table instrument for serving fish.

**Fish-Skin**, the covering of the flesh of marine animals. The rough skin of the dog fish or shark is used by the cabinet-maker, type founder, and others, as an abrasive material for smoothing wood-work and metals. A kind of shagreen is made of fish skin. The skin of the porpoise, beluga, seal, etc., are tanned; eel skins are used for making strong ropes, for connecting the swile and hand-staff of a threshing flail, and for other purposes. Sole skins and some others are used for clarifying coffee and liquors.

Fig. 191. — Fishing-Rod.

**Fish-Sound**, the swimming-bladder of a fish, many of which are prepared for isinglass; others, as cod-sounds, are salted for food; some are sold to the Chinese under the name of fishmaws.

**Fish-Strainer**, a metal colander with handles, for taking fish from a boiler. — An earthenware slab with holes, placed at the bottom of a dish, to drain the water from cooked fish.

**Fish-tail Burner**, a gas-jet which assumes a two-lobed form, like the tail of a fish.

**Fish-tail Propeller**, a single-winged propeller hinged to the stern-post and oscillating like the tail of a fish.

**Fish-Wear**, a dam in a river, or on the sea-shore, for stopping fish.

**Fitch**, a common name for the polecat, an European animal of the weasel tribe, the skin of which is much used for fur.

**Fitchburg R.R.** runs from Boston to Fitchburg, Mass., a distance of 50 m., with the following branches: Watertown, from North Cambridge to Waltham, 6.60 m.; Charlestown, 0.68 m.; Lancaster and Sterling, from South Acton to Marlborough, 12.42 m.; Peterborough and Shirley, from Ayer, Mass., to Mason, N. H., 23.62 m. The company also leases and operates the following lines: Vermont and Mass. R.R., from Fitchburg to Greenfield, 56 m., with branch to Turners Falls, 2.80 m., and the Troy and Greenfield R.R., from Greenfield to North Adams, 37 m., making a total of 189.12 m. operated. The offices of the Co. are in Boston, Mass. *Financial Statement*: Cap., stock, \$1,500,000; funded debt, \$1,000,000, consisting of \$500,000 7% bonds, payable 1894, and \$500,000 6%, payable 1897.

**Fitter**, in England, a coal-broker. — A weigher at the mint. — A tailor, one who tries on and adjusts articles of dress. — A gas-fitter is one who lays on pipes to houses, etc. — An out-fitter is a storekeeper who keeps ready-made garments on sale, or procures them properly made to order, etc.

**Fittings**, store fixtures; tackle for a ship; equipments; etc.

**Five-Twenties**, bonds issued by the U. States in 1862, 1864, and 1865, bearing interest at the rate of 6 per cent per annum, and redeemable at the pleasure of the government after five years, and payable twenty years from date. Total amount issued, \$843,660,150; total amount outstanding June 30, 1878, \$875,300. See NATIONAL DEBT.

**Fixature**, a gummy composition for the hair. See BANDOLINE.

**Fixed Oils**, the common greasy oils are so called from the high temperature they sustain before decomposing and giving off vapor. See FAT and OIL.

**Fixing**, in shipbrokers' parlance, in reference to a ship, finding it a freight; and, in reference to a freight, finding it a ship. — In photography, the cleansing of photographs from the sensitive layer not acted on by the light. The principal fixing agents are hyposulphate of soda, which may be used either for glass or paper pictures, and cyanide of potassium, which can be used only for the former.

**Fixtures**, the more permanent furniture of a counting-house or store, as the counters, desks, drawers, gas-burners, etc.

**Flacket**, a barrel-shaped bottle.

**Flacon**, **Flagon**, a flask or decanter; a carafe; a vessel with a narrow mouth; a smelling-bottle.

**Flag**, the ensign borne on the mast of a ship to designate the country to which it belongs; in the navy it is likewise made to denote the rank of the

officer by whom the ship is commanded. Different significations are also attached to plain flags of one simple color: thus, a yellow flag indicates that there is sickness of a dangerous character on board the vessel which bears it, or that the ship is performing quarantine; a white flag is well known among all nations as a flag of truce, and betokens a desire for a temporary cessation of hostilities, for the purpose of communication between hostile parties, or for burying the dead slain in battle; a black flag, on the other hand, is the emblem of piracy, or betokens a determination, on the part of those who hoist it, to resist to the last, and to give or take no quarter. When a flag is hoisted half-mast high, it is a mark of mourning; when it is hoisted upside down, it forms a signal of distress. A blue flag, with a square white centre, called the blue Peter, is hoisted when a vessel is about to sail, and is the signal of departure. A short triangular flag is called a burgee; a longer flag, of the same shape, a signal pendant; a square flag, with a triangular piece cut out of the end farthest from the halyards, with the point turned towards the centre, a cornet; and a very long narrow flag, resembling a strip of ribbon tapering to a point, which is borne at the mast-head, is called a pendant.

By the Act entitled "An Act to establish the flag of the United States," passed April 4, 1817, it was enacted: 1. That from and after the 4th of July, 1818, the flag of the U. States be 13 horizontal stripes, alternate red and white; that the union be 20 stars, white in a blue field. 2. That on the admission of every new state in the Union, one star be added to the union of the flag; and that such addition shall take effect on the 4th day of July then next succeeding such admission.

**Flageolet**, a small wooden musical instrument, played on by means of a mouthpiece, and furnished with holes or keys for fingering.

**Flail**, an instrument for threshing corn, consisting of the hand-staff, or piece held in the thresher's hand; a swile, or that part which strikes the corn; the caplins, strong leathern thongs, which unite the hand-staff and swile; and the middle-band, a leathern thong or fish-skin that ties the caplins together.

**Flake-White**, a sub-nitrate of bismuth. — Also a name for oxidized carbonate of lead in the form of scales or plates. When levigated, it is called body-white.

**Flambeau**, a kind of torch made of thick wicks, covered with wax, and used in the streets at night, at illuminations, and in processions. Flambeaux usually consist of four wicks or branches, about an inch in thickness, and three feet long, made of coarse half-twisted hempen yarn; and these, being suspended by one end, are coated with white or yellow wax, which is poured over them from a ladle until the requisite thickness be obtained.

**Flame**, gas or vapor in an incandescent state. The light emitted from pure flame is exceedingly feeble; illuminating power being almost entirely dependent upon the presence of solid matter. See ILLUMINATION.

**Flamingo**, a water-bird conspicuous for the bright scarlet or flame-colored patch upon its wings. Its body is smaller than that of the stork; but owing to the great length of neck and legs, it stands nearly five feet high, and measures six feet from the point of the beak to the tips of the claws. The *F.* of tropical America (*Phenicopterus ruber*) migrates in summer to the Southern States. Its plumage, which is of a deep red, is highly esteemed and always in demand.

**Flange**, in machinery, a projecting rim or rib.

The metal rim bent over in gas-pipes, water-pipes, etc., in order to join on to other lengths of the same. The term is also applied to the projecting outside circumference of a railway-carriage wheel, by which the wheel is prevented from running off the rails.

**Flannel** [Fr. *flanelle*; Ger. *Flanel*], a soft, open, woollen stuff, of which there are many kinds, milled, gauze, colored and checked, cricketing and house *F.*, blankets, etc. The manufacture of *F.*, which is very large, both in this country and in England, is almost the same as that of other woollen goods, though there are certain wools which are more used for *F.* than for any other textiles.

*F.* is highly recommended by medical men as a clothing, both in hot and cold countries. It acts as a gentle stimulus on the skin, and exercises the most beneficial action, by keeping the pores clean, and in a state most favorable to perspiration. This action is a species of friction similar in character, although inferior in degree, to that of the common flesh-brush or horse-hair glove, so long employed as a skin stimulant. *F.* has also the advantage of absorbing the perspiration as soon as emitted, and allowing its watery portion to pass off into the atmosphere almost as soon as formed, but this is not the case with cotton and linen fabrics. The different effects of *F.* and linen are particularly susceptible during brisk exercise. When the body is covered with the former, though perspiration be necessarily increased, the perspired matter freely passes off through the *F.*, and the skin remains dry and warm. If the same exercise be taken in linen shirts, perspiration, as in the former case, is indeed also increased, but the perspired matter, instead of being dispersed into the atmosphere, remains upon the linen, and not only clogs the pores of the skin, but gives a disagreeable sensation. From this property of *F.*, persons who wear it next the skin seldom catch cold from changes of temperature, even though perspiring profusely; but in similar cases, when linen or calico shirts are worn, chilliness immediately comes on, followed by sniffing, sneezing, and cough, and all the other symptoms of severe catarrh. — In washing *F.* it is recommended that they should only be put into warm water, by which method their color will be preserved, and they will be prevented from shrinking.

*Imp. duty*: wholly or part of wool, worsted, the hair of the alpaca goat, or other like animals, valued not over 40 cts. per lb., 20 cts. per lb. and 35 per cent; valued over 40 cts. per lb., 30 cts. per lb., 30 cts. per lb. and 35 per cent; valued over 60 cts. per lb., 40 cts. per lb., 40 cts. per lb. and 35 per cent; valued over 80 cts. per lb., 50 cts. per lb. and 35 per cent. — Flannel shirting, 50 cts. per lb. and 35 per cent.

**Flap**, a hinged leaf of a table or shutter.

**Flaring**, overhanging, as of the bows of a ship, the top side forward.

**Flash**, a liquor used to color spirits, and to give them a false strength. It is usually labelled *isinglass and burnt sugar*. Its composition is as follows: burnt sugar coloring, 1 gall.; fluid extract of capsicum or essence of cayenne,  $\frac{3}{4}$  pint, or enough to give a strong, fiery taste.

**Flashing**, in plumbing, a lap joint used in sheet-metal roofing, where the edges of the sheets meet on a projecting ridge; also a strip of lead leading the drip of a wall into a gutter.

**Flask**, a metal or other pocket dram-bottle. — A measure for holding gunpowder. — A shallow iron frame or casting-box, without top or bottom, used in foundries for moulding; the lower flask is called a drag. — A globular glass vessel for holding liquids, containing about half a gallon; in Holland 10 flasks make an anker. The flask of quicksilver from California is about 75 lbs.

**Flasket**, a long shallow basket with two handles.

**Flat**, a description of river-boat for conveying merchandise, which usually carries from 80 to 120 tons; those worked by the captains or owners are termed No. 1 flats. — Tasteless; vapid; insipid. — Lacking life and animation; depressed; as, the market is flat. — A stock-exchange term used to express the price of bonds, etc., when the sales are made without reference to accumulated interest. —

A rough piece of bone for a button-mould. — To preserve gilding by size. — A story or floor of a building, sometimes constructed so as to accommodate a family having the necessary suite of rooms, commonly called *French flat*. In New York, and some other large towns, houses are specially built for letting in these kinds of flats or floors with one common staircase.

**Flat-Bottomed**, a vessel with an even lower surface and but small depth.

**Flat-Cap**, a size of writing paper, usually 14 × 17 inches, put up in reams and bundles without being folded, and chiefly used for blank books.

**Flats**, plaited or braided straw, sewed and ready to be put in shape for bonnets or hats.

**Flat-Iron**, **Flattening-Iron**, a laundress's or workman's smoothing-iron.

**Flattening**, the operation of smoothing. — A mode of house-painting in which the color on the surface is left without gloss.

**Flattening-Mill**, a mill for rolling out metals by cylindrical pressure.

**Flat-Tool**, a turning-chisel used as a bottoming-tool in making boxes. It cuts on both sides, and on the end, which is square.

**Flavine**, a vegetable extract, in the form of a light-brown or greenish-yellow powder, which contains much coloring matter and tannin, and takes the place of quercitron bark. It gives a fine olive-yellow color to cloth.

**Flaw**, a crack; a fracture or defect in metals, gems, timber, etc.

**Flax** [Fr. *lin*; Ger.

*Flachs*; It. and Sp. *lino*; Port. *linho*], an annual plant of fragile appearance, sending up slender fibrous stalks, two or three feet high, with narrow alternate leaves and delicate blue flowers (Fig. 192). These are followed by globular, many-celled seed-vessels, containing bright, slippery, brown seed, flattened and elongated. The stalks of this plant are hollow pipes, surrounded by a fibrous rind, the filaments of which furnish to the manufacturer the material for cambric, linen, and other similar fabrics. The frequent mention of fine linen in Scripture, and the evidence which is afforded by the unrolling of Egyptian mummies that the fine linen of Egypt was actually woven from flax, is sufficient to prove that the same plant which we now employ furnished one of the most ancient manufactures known. For many ages, even down to the early part of the 14th century, Egyptian flax occupied the foremost place in the commercial world, being

Fig. 192. — FLAX.

sent in all regions with which open intercourse was maintained. Among Western nations it was, without any competitor, the most important of all vegetable fibres till towards the close of the 18th century, when, after a brief struggle, cotton took its place as the supreme vegetable fibre of commerce.

When flax is cultivated primarily on account of the fibre, the crop ought to be pulled before the capsules are quite ripe, when they are just beginning to change from a green to a pale brown color, and when the stalks of the plant have become yellow throughout about two thirds of their height. The various operations through which the crop passes from this point till flax ready for the market is produced are: (1) pulling, (2) rippling, (3) retting, and (4) scutching.

*Pulling and rippling* may be dismissed very briefly. Flax is always pulled up by the root, and under no circumstances is it cut or shorn like cereal crops. The pulling ought to be done in dry, clear weather; and care is to be taken in this, as in all the subsequent operations, to keep the root-ends even and the stalks parallel. At the same time it is desirable to have, as far as possible, stalks of equal length together,—all these conditions having considerable influence on the quality and appearance of the finished sample. As a general rule, the removal of the bolls or capsules by the process of *rippling* immediately follows the pulling, the operation being performed in the field; but under some systems of cultivation, as, for example, the Courtauld method, alluded to below, the crop is made up into sheaves, dried, and stacked, and is only bled and retted in the early part of the next ensuing season. The best rippler, or apparatus for rippling, consists of a kind of comb having, set in a wooden frame, iron teeth made of round-rod iron  $\frac{1}{16}$  of an inch asunder at the bottom, and  $\frac{1}{2}$  an inch at the top, and 18 inches long, to allow a sufficient spring, and save much breaking of flax. The points should begin to taper 3 inches from the top. A sheet or other cover being spread on the field, the apparatus is placed in the middle of it, and two rippers sitting opposite each other, with the machine between them, work at the same time. It is unadvisable to ripple the flax so severely as to break or tear the delicate fibres at the upper part of the stem. The two valuable commercial products of the flax-plant, the seeds and the stalk, are separated at this point. We have here to do with the latter only.

*Retting, or rotting*, is an operation of the greatest importance, and one in connection with which in recent years numerous experiments have been made, and many projects and processes put forth, with a view of remedying the defects of the primitive system or altogether supplanting it. From the earliest times two leading processes of retting have been practised, termed respectively water-retting and dew-retting; and as no method has yet been introduced which satisfactorily supercedes these operations, they will first be described.—*Water-retting*. For this—the process by which flax is generally prepared—pure soft water, free from iron and other materials which might color the fibre, is essential. Any water much impregnated with lime is also specially objectionable. The dams or ponds in which the operation is conducted are of variable size, but should be not more than 4 feet in depth. It is calculated that a dam 50 feet long, 9 feet broad, and 4 feet deep is sufficient to ret the produce of an acre of flax. The rippled stalks are tied in small bundles and packed, roots downwards, in the dams till they are quite full; over the top of the upper layer is placed a stratum of rushes and straw, or sods with the grassy side downwards, and above all stones of sufficient weight to keep the flax submerged. Under favorable circumstances a process of fermentation should immediately be set up, which soon makes itself manifest by the evolution of gaseous bubbles. After a few days the fermentation subsides, and generally in from ten days to two weeks the process ought to be complete; but everything depends upon the weather, and, as the steeping is a critical operation, it is essential that the stalks be frequently examined and tested as the process nears completion. When it is found that the fibre separates readily from the woody “shive” or core, the beets or small bundles are ready for removing from the dams. It is next spread, evenly and equally, over a grassy meadow, where it is left for about a fortnight, at the end of which time the fibres will have partly separated from the core and “bowed.” At this point advantage is taken of fine dry weather to gather up the flax, which is now ready for scutching, but the fibre is improved by stooking and stacking it for some time before it is taken to the scutching-mill.—*Dew-retting* is the process by which all the Archangel flax and a large portion of that sent out from St. Petersburg are prepared. By this method the operation of steeping is entirely dispensed with, and the flax is, immediately after pulling, spread on the grass, where it is under the influence of air, sunlight, night-dews, and rain. The process is tedious; the resulting fibre is brown in color, and is said to be peculiarly liable to undergo heating (probably owing to the soft heavy quality of the flax) if exposed to moisture and kept close placed with little access of air. Archangel flax is, however, peculiarly soft and silky in structure, although

in all probability water-retting would result in a fibre as good or even better in quality.

The theory of retting, according to the investigations of J. Kolb, is that a peculiar fermentation is set up under the influence of heat and moisture, resulting in a change of the intercellular substance—pecto-e, or an analogue of that body—into pectine and pectic acid. The former, being soluble, is left in the water, but the latter, an insoluble body, is in part attached to the fibres, from which it is only separated by changing into soluble metapectic acid under the action of hot alkaline lye in the subsequent process of bleaching.—To a large extent retting continues to be conducted in the primitive fashions above described, although numerous and persistent attempts have been made to improve upon it, or to avoid the process altogether. The uniform result of all experiments has only been to demonstrate the scientific soundness of the ordinary process of water-retting, and all the proposed improvements of recent times seek to obviate the tediousness, difficulties, and uncertainties of the process as carried on in the open air. The only modification of water-retting which has hitherto endured the test of prolonged experiment, and taken a firm position as a distinct improvement, is the warm-water retting, patented in America in 1846 by Robert B. Schenck. For open pools and dams Schenck substitutes large wooden vats under cover, into which the flax is tightly packed in an upright position. The water admitted into the tanks is raised to and maintained at a temperature of from 75° to 95° F. during the whole time the flax is in steep. In a short time a brisk fermentation is set up, gases, at first of pleasant odor, but subsequently becoming very repulsive, being evolved, and producing a frothy scum over the surface of the water. The whole process occupies only from 50 to 60 hours. A still further improvement, due to Mr. Pownall, comes into operation at this point, which consists of immediately passing the stalks, as they are taken out of the vats, between heavy rollers over which a stream of pure water is kept flowing. By this means, not only is all the slimy glutinous adherent matter thoroughly separated, but the subsequent processes of breaking and scutching are much facilitated.

A process of retting by steam was introduced by W. Watt, of Glasgow, in 1852, and subsequently modified and improved by J. Buchanan. The system possessed the advantages of rapidity—being completed in 10 hours—and freedom from any noxious odor; but it yielded only a harsh, ill-spinning fibre, and consequently failed to meet the sanguine expectations of its promoters.

*Scutching* is the process by which the fibre is freed from its woody core and rendered fit for the market. For ordinary water-retted flax two operations are required, first *breaking* and then *scutching*, and these are done either by hand-labor or by means of small scutching or lint mills, driven either by water or steam power. Hand-labor, aided by simple implements, is still much used in Europe; but the use of scutching-mills is now very general, these being more economical, and turning out flax of a much better quality. The breaking is done by passing the stalks between grooved rollers, to which in some cases a reciprocating motion is communicated, and the broken shives are beaten out by suspending the fibre in a machine fitted with a series of revolving blades, which, striking violently against the flax, shake out the bruised and broken woody cores. A great many modified scutching machines and processes have been proposed and introduced with the view of promoting economy of labor and improving the turn-out of fibre, both in respect of cleanness and in producing the least proportion of codilla, or scutching tow. Among them, and, we think, the most effective, is the *Breaking and Scutching Machine* lately introduced in the U. States by the editor of this work, and now owned by Mr. J. F. Dunton of Philadelphia.

*Dressing*. We have now to follow the scutched fibres to the great mills, where machinery does almost everything.—*Dividing*. The individual fibres, varying from 24 to 36 inches long, have different degrees of fineness at different parts; they are therefore divided into three, four, or five pieces each, to suit as many different kinds of manufacture. The flax is held between two side-wheels, and torn across by the edge of a revolving centre-wheel. The action is that of *tearing*, not *cutting*; since it is found that the spinning quality of the fibre is injured by a sharp transverse cut.—*Heckling*. The *heckle*, or *hackle*, is an iron comb, the teeth of which are very sharp, and are placed upright. The heckler, taking a lock of flax by the middle in his right hand, draws each half of the length repeatedly between the teeth of the comb, regulating the position of the flax with his left hand. This is done first on a coarse heckle, and then on a finer. The combed and straightened fibres are now called *line*, and the coarser and broken fibres *tow*. 100 lbs. of scutched flax produce rather more than 50 lbs. on an average of line, the rest being tow, boon, and dust. In the larger mills this process is now done by the *heckling-machine*. Heckles, or combs, are ranged round the circumference of a large cylinder; the fibres are fixed in a flat layer to a *flax-holder*, several such holders are adjusted to the machine, and their rotary action speedily heckles a large quantity of flax. Children are employed to fill and empty, place and replace, adjust, and manage the flax-holders; all else is conducted automatically. Revolving brushes of bristle clean

off any refuse tow from the teeth of the heckles. — *Sorting.* The line is divided by skilful sorters into as many as half a dozen different degrees of fineness, partly by the eye and partly by the touch; and each quality is rapidly placed in a separate compartment by itself. — *Spreading, Drawing, and Roving.* The sorted line is next converted into ribbons, or slivers. For this purpose it is spread upon a feeding-cloth in such a manner that the ends of the second strick reach the middle of the first. In this way a uniform thickness is preserved, since the heckled stricks are thicker in the middle than at the ends. The flax is then passed between one pair of rollers, which deliver it through-gills or heckling-points to a second pair, which, moving with much greater speed than the first, increase the length and diminish the thickness of the flax. During this operation

Fig. 193. — SPREADING-FRAME.

the flax receives no twist, but is converted into a flat, narrow tape or ribbons, which is received into a tin can. When the can is full it is taken to a drawing or spreading frame (Fig. 193), where a number of slivers are united and drawn into one length. The frames are attended by young women, each of whom has the charge of four. The slivers next go to the *roving-frame*, where they receive a slight degree of twist and are wound upon bobbins preparatory to spinning.

*Spinning.* The spinning of flax differs little from the throstle-spinning of cotton (see CORROS), but the fibres of flax have not the same tendency to entangle themselves together as those of cotton, therefore it is necessary to moisten them with water to make them adhere to each other, and also to make them more pliable and easy to twist. Formerly the flax for machine-spinning was moistened with cold water, but a great improvement has been effected by substituting water at the temperature of 120°, which allows a much finer and more uniform thread to be spun, and double the length to be obtained from a given weight of flax. The warm water is contained in a trough, which extends the whole length of the spinning-frame, and the rapid motion of the spindle causes a dewy spray to be continually thrown off. A great inconvenience was for a time experienced by the attendants, whose clothes were completely wetted in an hour or two by this minute spray, but the use of water-proof aprons has been found a sufficient remedy. This operation, however, produces a hot steaming atmosphere, which is painful to casual visitors of a flax-mill, though not unpleasant to the operatives. — The yarn, by doubling, is made into linen thread, which is bleached and formed into balls or reels. The yarn itself is wound upon reels and then made up into leas, hanks, bundles, etc., as in the following invoice.

TWO AND A HALF YARD REEL.

120 threads of 2½ yards....	300 yards, or one lea.
10 leas.....	3,000 yards, or 1 hank.
20 hanks.....	60,000 yards, or 1 bundle.

(Three bundles are usually put together in one bunch.)

ONE AND A HALF YARD REEL.

100 threads, or 1½ yards....	150 yards, or half a lea.
10 half-leas.....	1,500 yards, or 1 hank.
40 hanks.....	60,000 yards, or one bundle.

(Six bundles are usually put together in one bunch.)

The fineness of linen yarn is reckoned by the number of leas to the pound weight. In sorting line, the various qualities are divided into 2, 3, 3½ pounds, etc., as above mentioned. In linen yarns the bundle of 60,000 yards is sometimes called by its number of leas per lb., or by the weight of the

bundle. Thus a bundle of 25 leas to the lb. weighs 8 lbs.; a bundle of 50 leas to the lb. weighs 4 lbs.; a bundle of 100 leas to the lb. weighs 2 lbs.; so that 8 lbs. and 25 leas, and 4 lbs. and 50 leas, and 2 lbs. and 100 leas, are synonymous terms, as far as the size is concerned. In sorting, a certain quality of line will spin to a certain size or weight per bundle, and it was formerly the custom of line-sorters to call certain qualities 2 lbs., 3 lbs., 3½ lbs., 4 lbs., etc., because that quality of line would spin to that weight per bundle. The same standard and name are still retained by line-sorters for the same quality of line; but from improvements in machinery, and other causes, 5½ line can now be spun to the size of 3 lbs. the bundle, and even finer.

*Weaving.* When flax has once been spun into yarn, its subsequent applications are very numerous. Some is twisted into thread, for sewing or for lace-making. Some (and this the greater portion) is woven into linen. Other flax goods are duck, drill, check, drabber, tick, huckaback, diaper, damask, towelling, sheeting, dowlas, sackcloth, sail-cloth; while a much-used combination of flax with cotton is called union. Variations in the quality of the flax, the thickness and closeness of the yarn, the mode of dressing, the arrangement and movements of the loom in dressing, and the finishing operations combine to bring about the difference in these several kinds of goods. Jute has lately come into competition with flax for some of the coarser varieties. See LOOM, and WEAVING.

The celebrated Courtrai flax of Belgium is the most valuable staple in the market, on account of its fineness, strength, and particularly bright color. There the flax is dried in the field, and housed or stacked during the winter succeeding its growth, and in the spring of the following year it is retted in crates sunk in the sluggish waters of the river Lys. After the process has proceeded a certain length, the crates are withdrawn, and the sheaves taken out and stooked. It is thereafter once more tied up, placed in the crates, and sunk in the river to complete the retting process; but this double steeping is not invariably practised. When finally taken out, it is unloosed and put up in cones, instead of being grassed, and when quite dry it is stored for some time previous to undergoing the operation of scutching. In all operations the greatest care is taken, and the cultivators being peculiarly favored as to soil, climate, and water, Courtrai flax is a staple of unapproached excellence.

An experiment made by Professor Hodges of Belfast on 7,770 lbs. of air-dried flax yielded the following results: By ripping he separated 1,946 lbs. of bolls, which yielded 910 lbs. of seed. The 5,824 lbs. (52 cwt.) of flax straw remaining lost in

Fig. 194. — FIBRE OF ROUGH RUSSIAN FLAX (magnified).

steeping 13 cwt., leaving 39 cwt. of retted stalks, and from that 6 cwt. 1 qr. 2 lbs. (702 lbs.) of finished flax was procured. Thus the weight of the fibre was equal to about 9 per cent of the dried flax with the bolls, 12 per cent of the balled straw, and over 16 per cent of the retted straw.

According to the determinations of Wiesner (*Die Rohstoffe des Pflanzenreiches*), the fibre ranges in length from 20 to 140 centimetres, the length of the individual cells being from 2.0 to 4.0 millimetres, and the limits of breadth between 0.012 and 0.025 mm., the average being 0.016 mm.

Among the circumstances which have retarded improvement both in the growing and preparing of flax, the fact that, till comparatively recent times, the whole industry was conducted only on a

domestic scale has had much influence. At no very remote date it was the practice in Scotland for every small farmer and cottier not only to grow "lint," or flax, in small patches, but to have it retted, scutched, cleaned, spun, woven, bleached, and finished entirely within the limits of his own premises, and all by members or dependants of the family. The same practice obtained in the U. States. Outside of the cities and of the homes of great planters there was scarcely a housewife or damsel of whom it might not be said, "She layeth her hands to the spindle, and her hands hold the distaff." From a series of papers written between 1787 and 1791 by Mr. Tench Coxe, Commissioner of the Revenue, and for several years Assistant Secretary of the Treasury, it appears that manufactures from flax and hemp had become an established and very important industry; he enumerates, among articles "manufactured in a household way," seines and nets of various kinds, twine and packthread, sail-cloth, tow-cloth, white and checked shirtings, sheetings, towelling, table-linen, bedticks, hosiery, sewing-thread, and seine-thread lace. Among the flax products "manufactured in a family way" in Massachusetts and Rhode Island, during the first 9 months of 1791, Mr. Coxe specifies 25,265 yards of linen cloth. The census of 1810 returned 21,211,262 yards of flaxen cloths made in families; of this, New York produced 5,303,000 yards; Virginia, about 5,000,000; Pennsylvania, 3,000,000; Connecticut, 2,250,000; New Hampshire, 1,000,000. Thus the flax industry was long kept away from the most powerful motives to apply to it labor-saving devices, and apart from the influence of scientific inquiry for the improvement of methods and processes. As cotton came to the front just at the time when machine-spinning and power-loom weaving were being introduced, the result was that in many localities where flax crops had been grown for ages the culture gradually drooped and ultimately ceased. The linen manufacture by degrees ceased to be a domestic industry, and began to centre in and become the characteristic factory employment of special localities, which depended, however, for their supply of raw material primarily on the operations of small growers, working, for the most part, on the poorer districts of remote, thinly populated countries. The cultivation of the plant and the preparation of the fibre have, therefore, even at the present day, not come under the influence (except in certain favored localities) of scientific knowledge and experience, and the greater part of the flax in use at the present moment is prepared precisely by the processes employed in Egypt when the descendants of Jacob dwelt in the land of Goshen.

In England and Scotland the acreage under flax is now so limited, and it has decreased with such steadiness and rapidity, that, as a crop, flax may be regarded as practically extinct in these countries. In Ireland the cultivation of flax has always occupied a relatively much more important position than it has in the sister countries, though there also the experience is that it is a rapidly declining agricultural crop.

In this country, in connection with, and largely as a consequence of, the unusual demand for lint and tow to be consumed in multifiber fabrics of house manufacture, sufficient quantities of seed were produced, not only for house use and internal commerce, but to leave a large surplus for foreign export. In an official abstract of the exports from the U. States for the year ending Sept. 30, 1791, Mr. Coxe specifies 58,492 casks of flax-

seed. This is assumed to be equivalent to 292,460 bushels, — that is, over half the entire product reported for 1860, and a fraction over one sixth of that reported for 1870. Among the exports of the same year were 18,600 pounds of lint, and 6,850 yards of tow cloth; but as the manufacture of cotton fabrics in factories increased, this universal household industry, which had greatly contributed towards keeping families at home, united and contented, by affording a profitable employment to both sexes and all ages, gradually declined to a vanishing point. One consequence was that, while the demand for seed was rapidly increasing, production either remained stationary, or decreased. The cotton famine, consequent upon our civil war, greatly stimulated the cultivation for a few years from 1862 upwards; but since the restoration of the cotton crop, and the return of cotton fabrics to nominal prices, the tide has turned in the States east of the Mississippi, and production of seed and lint is again on the decline. In 1870 the production of fibre returned for the census amounted to 27,133,034 lbs. In the younger States west of the Mississippi, chiefly in Minnesota, Kansas, Iowa, Oregon, and California, the upward tendency in production as yet shows no sign of declining, but seems to grow with accumulating force. Unfortunately flax is grown in this country only for its seeds, and the few manufactures we have must import the fibre from Canada and Europe. Among the obstacles alleged in the way of profitably growing the fibre are the following: 1. The want of a regular and accessible market. 2. The labor involved in pulling flax on a large scale is greater than can be secured at the proper season at wages which will leave any margin for profit. 3. The process of "rotting" or eliminating the fibre from the stalk "in the old-fashioned way" is tedious, and thought to be unhealthy. 4. Most farmers do not sufficiently understand the rotting part of this process, and are therefore very liable to injure the fibre by some failure, either in method or degree. 5. The processes of breaking, scutching, and hackling by hand are very disagreeable, necessarily involving the operator in an atmosphere thick with dust and dirt, and yet requiring skilled workmen, such as it is often quite impracticable to secure. 6. Owing to the cheapness of labor in Europe, it is impracticable to compete with European production without more protection by legislation than is at present granted. The complaint is made that flax-growing has received much less legislative encouragement than either wool or silk. But whatever of weight may be attached to this list of discouragements, they were all to be met and overcome in European production, except that of higher-priced labor, which may be amply counterbalanced in this country by cheaper real estate, both for production and for manufactures, cheaper water-power, fuel, and machinery, and by the use of the new Breaking and Scutching Machines mentioned above, etc.

Rensselaer County, in New York State, which is the seat of linen industry in this country, has 20 mills for dressing flax, and 2 for manufacturing yarn and twine. The latter consumes 3,000 lbs. of fibre daily when running on full time. Much of the fibre used here is imported from Canada and Europe at rates cheaper than American farmers are willing to supply it.

The statement on the following page embodies the latest available returns regarding the acreage and produce of flax in all the countries where the plant is cultivated on account of its fibre.

The Imports of Flax Products into the U. States for the ten years, 1868-1878, were as follows:—

YEARS.	Raw Flax.		Linens.	Not specified.	Flaxseed.		Total value.
	Cwt.	Dollars.			Dollars.	Bushels.	
1878.....	80,900	1,177,224	11,300,758	2,322,842	1,200,645	1,880,233	17,474,162
1877.....	89,940	1,243,664	11,509,894	2,406,008	1,445,625	1,916,249	17,075,217
1876.....	73,180	1,060,437	12,227,366	2,218,110	2,755,726	3,859,406	16,955,979
1875.....	86,410	1,112,465	14,124,947	2,478,235	3,783,944	6,227,612	23,942,679
1874.....	68,520	942,638	14,081,428	3,391,327	2,648,321	4,391,680	22,716,483
1873.....	83,420	1,137,737	16,271,590	4,156,801	2,453,428	3,854,461	25,420,589

1871.....	73,440	684,832	13,590,702	4,500,263	.....	5,160,747	23,916,474
1870.....	38,540	665,962	12,716,656	3,547,796	.....	4,141,394	21,011,718
1869.....	39,060	669,411	13,990,341	2,562,546	.....	1,543,443	18,755,741

Area under Flax, and Gross Produce of Various Countries.

COUNTRIES.	Statute Acres.	Stones per acre.	Tons.
Austria, 178,397 jochs.....	253,323	21.48	34,009
Belgium, 57,945 hectares.....	140,901	33.59	29,580
Denmark.....	17,686	20.00	2,211
Egypt..... (estimated)	15,000	20.00	1,875
France, 78,774 hectares.....	194,571	34.84	42,368
Germany, 214,835 hectares.....	539,642	22.50	74,621
Great Britain.....	7,481	28.50	1,333
Greece.....	957	20.00	119
Holland, 19,444 hectares.....	48,027	31.77	9,536
Hungary, 14,017 jochs.....	19,903	20.00	2,488
Ireland.....	123,392	28.74	22,159
Italy, 81,386 hectares.....	201,023	18.14	22,791
Russia.....	1,928,568	20.00	241,071
Sweden.....	37,500	20.00	4,688
Total.....	3,518,944	.....	488,849

It thus appears that the breadth of lands under flax in Russia alone is little less than four sevenths of the entire acreage devoted to the production of the fibre, and that it alone produces practically one half of the total produce of the world.

**Imp. duty:** Flax straw, \$5 per ton; flax not heckled or dressed, \$20; heckled, known as dressed line, \$10; tow, \$10; brown and bleached linens and other manufactures of flax, or of which flax shall be the component material of chief value, valued at 30 cents or less per sq. yard, 35 per cent; valued above 30 cents per sq. yard, 40 per cent. See LINSEED, LINSEED OIL, LINEN, YARN, etc.

**Flax-Comb**, a hatchel or heckle for preparing flax.

**Flax-Cotton.** Many experiments have been made as to the possibility of preparing and spinning flax in the same way as cotton, and combining it with wool in mixed goods. Chevalier Claussen, a few years ago, hit upon a plan for effecting this. By a particular mode of treatment the fibres can be separated from the boon without steeping; the resinous gum, it is true, is still present; but this does not prevent the fibres from being spun into thick yarns for coarse fabrics, such as sail-cloth, canvas, and cordage. For finer yarns, instead of two or three weeks of steeping or retting, Claussen boiled the flax for six hours in a solution of potash or lime, which not only removed the gum, but left the fibre very smooth and clear. If to be prepared and spun in the manner of cotton, he cut the flax into lengths about equal to those of cotton, exposed them to the action of alkaline and acid solutions, and generated carbonic acid gas, which burst open each little fibre, and separated it into minute filaments. The fibres thus lost the peculiar rigidity which belonged to them originally, and became a soft and downy mass, to which he gave the name of *flax-cotton*, or *cottonized flax*. This flax-cotton can be carded and spun into

yarns, which may be used either by themselves or in combination with cotton, wool, or silk. Chevalier Claussen was so sanguine as to believe that flax-cotton could be produced so cheaply as 44 cts. per lb., and that it would revolutionize the cotton-trade. That flax can in this way be prepared for the spinner in a much shorter time than by retting and the old routine of processes, that it takes a good dye, and that it can be combined in various ways with silk, cotton, and wool, have been clearly proved; but manufacturers have not yet indorsed Claussen's views as to the value of the new material.

**Flaxen**, made of flax; linen goods. — Resembling, or having the color of, flax.

**Flax-Mill**, a factory where flax is spun into linen goods.

**Flaxseed.** See LINSEED.

**Flax-Silk**, a stuff made of flax and silk, and having the glossiness of silk.

**Flax-Thread**, twisted flax-yarn.

**Flax-Yarn.** See YARN.

**Flay**, to strip or cut off the skin.

**Fleabane**, a name given to various plants of the genus *Erigeron*, from their supposed efficacy in driving away flies.

**Fleak**, a twist or lock; a hurdle or grating.

**Fleam**, a large strong instrument, used by veterinary surgeons, for letting blood from horses and other animals.

**Flecked**, mottled, dappled, spotted.

**Fleece**, as much wool as is shorn from one sheep; the weight varies according to the breed and the climate. — See WOOL.

**Fleet**, a navy; a collection of ships or sailing boats. — An inlet or creek — Swift; shallow.

**Fleet-Dyke**, an embankment for preventing inundation.

**Fleeting-Dish**, a skimming-bowl.

**Flemish-Bricks**, paving bricks of a yellowish color, harder than the ordinary bricks.

**Flemish-Horse**, in marine parlance, an additional foot-rope at the ends of topsail yards.

**Flench**, **Flinch**, to strip off in layers.

**Flench-Gut**, the blubber of a whale laid out in long slices in the hold before barrelling.

**Fleensing**, the operation of cutting the blubber from the whale.

**Flesh**, butcher's meat; the carcass of any animal killed for food.

**Flesh-Brush**, a brush for rubbing the surface of the body, of which there are several kinds, made either of horse-hair or fine wire, etc.

**Flesh-Color**, the color of the flesh; white with a blush of pink.

**Flesh-Fork**, a cook's fork for trying meat, and taking it from the boiler.

**Flesh-Hook**, a hook to hang meat.

**Fleshing-Knife**, a convex knife, with a sharp

edge, used by curriers in removing the flesh and fat from the inner surface of the hide.

**Fletador** [Sp.], the freighter of a ship.

**Fleurage** [Fr.], oatmeal or bean-meal for gruel.

**Fleuret** [Fr.], a sort of coarse silk; a kind of narrow ribbon; ferret-ribbon.—An instrument to practise fencing with.

**Fleury.** See **BURGUNDY WINES.**

**Flies**, artificial insects, which are dexterously made of bright feathers, silk, etc., for the use of anglers for fish in rivers and lakes.

**Flight**, a series of steps or stairs from one floor to another without turning.

**Flighter**, a cooler's horizontal vane, revolving over the surface of wort, to produce a circular current in the liquor.

**Flimsy**, a loosely woven fabric, wanting in firmness of texture.—A name among reporters for manifold copies of articles of news written on tissue-paper.

**Flinking-Comb**, a dressing-table comb for the hair.

**Flint** [Fr. *Pierre à fusil*; Ger. *Feuerstein*], a mineral composed almost entirely of silica. Few parts of the world are without it. Among its useful applications, two are gradually becoming obsolete. The flint used with the steel and the tinder-box is yielding to the lucifer-match; while the flint of the gunlock, in pistols and muskets, is almost superseded by the percussion-cap. The present use of flint, in its native state, is chiefly in making glass and earthenware.

**Flint and Père Marquette R.R.** runs from Monroe to Luddington, Mich., a distance of 253.31 m., with branches from Bay City to East Saginaw, 12.35 m., and from Flint to Otter Lake, 14.41 m.; total length of line, 280.07 m. This Co., whose offices are in East Saginaw, Mich., was organized in 1857, and in 1872 it was consolidated with the Bay City and East Saginaw, the Holly, Wayne, and Monroe, and the Cass River and Flint River R.R. Co. The road was opened in 1874. The Co. has secured a land grant of 3,840 acres per mile of road, and these have been divided into several trusts to secure an equal number of mortgages on the road and lands. *Financial statement*: Cap. stock, \$3,208,300; funded debt, \$7,157,905.50, as follows,—1st mortgage L. G. bonds, 1st series, \$1,000, payable 1880, interest 7% (May and Nov.); 1st mortgage L. G. bonds, 2d series, \$9,000, payable 1887, interest 7% (Jan. and July); 1st mortgage L. G. bonds, 3d series, \$1,997,000, payable 1888, interest 8% (Mar. and Sept.); F. and H. lease bonds (\$25,000 per ann.) \$375,500, payable 1888, interest 10% (May and Nov.); B. C. & E. Saginaw R.R. bonds guaranteed \$100,000, payable 1882, interest 10% (Jan. and July); Bay Co. bonds (loan to same) \$75,000, payable 1887, interest 10% (Mar. and Sept.); Holly, Wayne, & Monroe R.R. bonds \$1,000,000, payable in 1901, interest 8% (Jan. and July); Construction Loan Bonds, \$11,405.50, payable 1878, interest 8% (Jan. and July); Consolidated Sinking Fund, \$3,559,000, payable 1902, interest 8% (May and Nov.).

**Flint-Glass.** See **GLASS.**

**Flintlock**, the old-fashioned musket-lock, with a flint fixed in the hammer, for striking on the steel pan.

**Flint-Powder**, pulverized flint used in manufactures as a polishing material.

**Flitch**, in the pork-trade, the side of a hog salted and cured.

**Flittern-Bark**, the bark of young oak-trees, as distinguished from that of old oak-trees, which is called timber-bark, and is less valuable to tanners. There is a third sort called coppice-bark,

which is the bark stripped off oak grown as coppice from stems or stools.

**Float**, the water-gauge of a steam-boiler, attached to a valve in the feed-pipe, and supported upon the surface of the water by a counter-weight (see F, Fig. 37).—The buoy of a fishing-line, whose motion indicates the bite of a fish.—An inflated bag or pillow to sustain a person in the water.—A raft of timber 18 feet square by 1 foot deep.—A plasterer's trowel, of which there are several kinds, used in spreading the plaster on to a wall.—A file whose teeth are parallel and unbroken by a second row of crossing teeth.—A serrated plate used by shoemakers for rasping off the pegs inside the boot or shoe.

**Float-Board**, one of the boards fixed on the paddle-wheels of steamers, and to undershot water-wheels, by which they act.

**Floating-Bridge**, a flat-bottomed ferry steam-boat in a harbor or river, running on chains laid across the bottom, and constructed for the conveyance of passengers, goods, and vehicles.

**Floating-Light**, a life-buoy carried at a ship's stern, with a light or lantern, which can be dropped into the sea, in order to save any one falling overboard at night.—Also a light attached to a boat or the hull of a vessel moored over a rock or a shoal to serve the purpose of warning to mariners.

**Floating-Pier**, a landing stage that rises and falls with the tide.

**Floatsam.** See **FLOTSAM.**

**Flock**, an indefinite number of sheep, kept together under one shepherd.—The short refuse of a wool-factory, which being scoured, pulverized in a mill, and dyed, is used to make flock-paper.—The refuse or waste of wool and cotton, which is cut to a very short staple by machinery, and used for stuffing upholstery, mattresses, etc.

**Flock-Paper**, wall-hangings in which finely pulverized and dyed wool is laid on the surface of paper and attached by size.

**Flogging-Chisel**, a chisel of large size, used in chipping off certain portions of a casting.

**Flood-Gate**, a sluice in rivers, canals, or docks, that may be opened or closed at will, to admit or exclude water.

**Flood-Tide**, the advancing tide increasing towards high water.

**Flookan**, earth or clay of a slimy consistence.—In mining, the shifting of the vein or lode by a cleft, etc.

**Floor**, the timber, bricks, etc., of the platform which forms the base or surface of any story of a house, and on which the planks or flooring are laid. The name in a general sense applies to all that part of a building on the same level, and varies according to the height from the ground, as first floor, second floor, etc.—The bottom of a vessel on each side of the keelson.

**Floor-Cloth, Oil-Cloth**, a heavy painted fabric for covering floors. This useful and ornamental fabric, which now forms an important branch of American manufacture, originated in Great Britain, about the year 1740, when a manufactory of it was established at Knightsbridge, near London, by Mr. Smith. It was originally made of narrow canvas sewn together like sail-cloth, to which successive coats of paint were applied; but the seams proving inconvenient, a canvas was wove for the purpose, about four yards wide; it was then extended to seven yards in width, and afterwards to nine, which is the widest at present made. The manufactory at Knightsbridge, now carried on by Mr. Baber, is the largest establishment of the kind,—the com-

mon dimensions of the oil cloths produced there being 20 yards by 8, and 30 yards by 7, giving, therefore, entire pieces of 160 and 210 square yards without seams.

**Manufact.** The canvas is first cut into pieces of the required length and breadth, and the edges are fastened to the four sides of a large frame, which are then drawn apart by machinery, to stretch the canvas as tightly as possible, somewhat in the manner adopted in straining canvas for Berlin-wood work. The position of the frame is vertical, the height being equal to the width of the canvas; when this exceeds 6 or 8 feet, the upper part is reached by means of light scaffolds or stages, which the workmen can move from one end of the piece to the other throughout the entire length, whenever occasion may require it during the process of painting. The canvas is then in a proper condition for the reception of the size and paint, which is laid on to render it fit to undergo the final process of printing. It is first coated with strong size on both sides, and while this is still damp the canvas is rubbed all over with pumice-stone, to render it smooth and even. When the size is dry, the canvas receives two coats of paint on each side. The first coat is very thick, being more like mortar than paint; it is laid on in lumps and patches, and smoothed all over the web with a broad flat trowel, in a manner resembling that in which plaster is laid on a wall. When this is thoroughly dry, the surface is again rubbed with pumice-stone, and a second coat of thinner paint is laid on with a brush. The under side of the canvas requires nothing more to be done to it after this, but the upper side receives two or three more coats of thin paint, being rubbed with pumice-stone after each coat has been laid on, in order to produce a smooth surface to receive the printed pattern. The canvas is now removed from the frame and wound round a roller, from which it is allowed to pass over a flat table, to receive the impression of the blocks. Formerly the patterns were stencilled, as the walls of rooms were before paper-hangings were introduced; that is to say, they were produced by putting coloring matter on the surface, through holes and lines punched in a sheet of tin or paste-board, so as to form the design required; but now the printing is effected by blocks, a separate block being required for every color introduced into the pattern. The blocks are about 15 inches square, and are made of deal, faced with wood of a fine close grain, with a handle at the back; that part of the pattern which each block is required to imprint on the canvas is left on its surface in relief, the remaining part being cut away, as in a wood-engraving. The surface of the projecting portion of each block is further cut into small squares, technically called teeth, by narrow grooves crossing each other at right angles. This is done to effect an equal distribution of the paint, for if the surface of the projecting part of the blocks were left smooth and even, it would take up the coloring matter unevenly, and transfer it to the floor-cloth in irregular patches. The impression is effected by applying the surface of the block to a pad or cushion charged with the color required; after which it is transferred to the floor-cloth by means of the handle at the back, and pressed forcibly upon it. It is then removed, charged again with color, and pressed on the canvas close by the side of the first impression, points being placed at the corners of the blocks to insure the regularity of the joining of the pattern. This process is repeated until the whole of the floor-cloth has been covered with that part of the pattern which is imprinted by the first block that is used, after which the blocks intended to convey the remaining colors to its surface are used in a similar manner, until the pattern is complete. It must then be allowed to dry, care being taken to give the coloring matter sufficient time to harden thoroughly before the floor-cloth is taken into use. The borders along the sides of narrow pieces of floor-cloth intended for passages are produced in the same manner, by blocks of the necessary width, similarly prepared for the purpose. It should be stated that worn-out Brussels carpets afford a good foundation for floor-cloth, and may be converted into that material at any floor-cloth manufactory. — A cheap kind of floor-cloth for the protection of carpets and stair carpets, somewhat similar to oil-baise, or oil cloth for table-covers, is made on a foundation of thin calico, and thinly coated with paint on one side only, after which the pattern is imprinted in the usual way, or by rollers. — *Kamptulicon* is a substance intended to present certain advantages over painted canvas as a floor-covering. It is made of cork reduced to a fine powder, India-rubber, linseed-oil, and one or two other substances. These ingredients are kneaded up into a kind of dough, which is pressed out into sheets by rolling with steam-heated cylinders. When cold, these sheets may at once be used as a floor-covering, or may be painted with any ornamental device. It forms a more noiseless, elastic, and dry floor-covering than the common one.

**Imp. duty:** Oil-cloths for floor, stamped, painted, or printed, valued at 50 cts. or less by sq. yd., 35 per cent.; valued over 50 cts. per sq. yd., 45 per cent. For carriage-floors, too thin and frail for recognized floor oil-cloths, 45 per cent.

**Floor-cloth Canvas,** a coarse fabric of mixed hemp and flax, varying in width from one to eight yards or more.

**Flooring,** in carpentry, the laying down of boards close together horizontally, with some kind of timber support underneath to which the boards can be nailed.

**Florant,** a mining term for fine-grained tin, either scarcely perceptible in the stone, or stamped very small.

**Floree,** powder blue or indigo.

**Florence Leaf.** See **DICTIONARY LEAF.**

**Florence-Oil,** olive-oil sold in peculiar flasks known as Florence flasks.

**Florentine,** a kind of wrought satin made in Florence. — A lake color extracted from the shreds of scarlet cloth.

**Flores,** a commercial classification of indigo, the best quality of dye from Nos. 7 to 9.

**Floretoune,** a Spanish wool.

**Floretta,** refuse of floss-silk.

**Florida,** the most southern of the U. States, is a large promontory extending S. into the Atlantic Ocean, its S. and W. coasts forming in part the N. and E. shore line of the Gulf of Mexico. Its boundaries are comprised between  $24^{\circ} 30'$  and  $31^{\circ}$  N. lat., and  $80^{\circ}$  and  $87^{\circ} 45'$  W. lon. *F.* makes the S. boundary of the State of Georgia, and in part that of Alabama, from which it is separated on the N. W. by the river Perdido. The Atlantic washes its E. and the Gulf of Mexico its S. and W. coasts, constituting a seaboard of 1,146 m. On the S.-E. it is separated from the Bahamas by the Straits of Florida. It points toward Cuba on the S., Havana being about 110 m. from Key West. Its entire length from Perdido River to Cape Sable is about 700 m., its mean breadth, 90 m. Area, 59,268 sq. m., or 37,331,520 acres, of which 2,373,541 acres were in 1870 included in farms. Population about 200,000. Besides its seaports (given below), the principal cities of *F.* are Jacksonville, on the St. John's River, a flourishing city much resorted to by invalids from the Northern States on account of the salubrity of its climate (pop. 15,000); Tallahassee, the capital (pop. 2,500); and St. Augustine (pop. 24,000). — The peninsula proper terminates on the S. in Cape Sable; but a remarkable chain of rocky islets, called the *F. Keys*, begins at Cape *F.* on the E. shore, extends S.-W. nearly 200 m. in a direction generally conforming with that of the coast, and ends in the cluster of sand-heaped rocks known as the *Tortugas*, from the great number of turtle formerly frequenting them. S. of the bank on which these Keys rise, and separated from them by a navigable channel, is the long, narrow, and dangerous coral ridge known as the *F. Reef*. This group of keys and reefs is washed on the S. by the constant current of the Gulf Stream. The most important of the Keys is Key West (which see below). The Gulf coast of the State is intersected by numerous bays, among which are Pensacola, Choctawhatchee, St. Andrew's, Appalachicola, Appalachee, Tampa, Charlotte, Ponce de Leon or Chatham, and *F. Bays*, the last lying between the Keys and mainland. The chief rivers are St. John's, navigable about 100 m. for vessels of moderate draught, and emptying into the Atlantic after a northerly course of 300 m.; Indian River, a long narrow lagoon on the E. coast, which it is proposed to unite by a canal with the St. John's; the Suwanee and Ocklockonee, which rise in Georgia and flow into the Gulf of Mexico; the Appalachicola, formed by the Chattahoochee and Flint Rivers, and emptying into the bay of the same name; Choctawhatchee, Escambia, and Perdido, also flowing into the Gulf. The St. Mary's makes for some distance the N. boundary of the State.

*F.* has also numerous lakes, some of which are navigable. Lake Okeechobee, in the Everglades, is about 40 m. long and 30 broad. — The surface of *F.* is generally level, the greatest elevation being not more than 300 feet above the sea. The most remarkable feature is the immense tract of marsh filled with islands in the S. part of the state, called the Everglades, and by the Indians, "grass-water." Between the Suwanee and Chattahoochee the country is hilly; the western portion of the State is level. De Bow designates the lands as high-hummock, low-hummock, swamp, savanna, and pine. The soil is generally sandy, except in the hummocks, where it is intermixed with clay. These hummocks vary in extent from a few to thousands of acres, and are found in all parts of the State. They are usually covered with a heavy growth of red, live, and water oak, magnolia, pine, and dogwood. When cleared they afford desirable openings for cultivation. The savannas are rich alluvions on the margins of streams or lying in detached tracts, yielding largely, but requiring ditching and dyking in ordinary seasons. In the "barrens," as the pine forests are called, the soil is very poor, and thickly overgrown with pine and cypress. The district comprised in the Everglades is impassable during the rainy season from July to October. It is about 60 m. long by 60 broad, covering most of

Fig. 195. — SEAL OF FLORIDA.

of the territory S. of Lake Okeechobee, or Big-water. The islands with which this vast swamp or lake is studded vary from one fourth of an acre to hundreds of acres in extent. They are generally covered with dense thickets of shrubbery or vines, occasionally with lofty pines and palmettos. The water is from 1 to 6 feet deep, the bottom being covered with a growth of rank grass. The vegetable deposit of the Everglades is considered well adapted to the cultivation of the banana and plantain. Another remarkable feature of *F.* is the subterranean streams which undermine the rotten limestone formation, creating numerous cavities in the ground called "sinks." These are inverted conical hollows, or tunnels, varying in extent from a few yards to several acres, at the bottom of which running water often appears. A most remarkable spring, situated 12 m. from Tallahassee, has been sounded with 250 fathoms of line before finding bottom. The outflow forms a beautiful lake, transparent and cold as ice even in the hottest weather. The great sink of Alachua County is a subterranean passage by which the waters of the Alachua savanna are supposed to discharge themselves into Orange Lake. In fact, the geological structure of the State is remarkable, much of its surface seeming a crust through the openings of which underground lakes and rivers force their way. — *Climate.* *F.*, except in the vicinity of the swamps, possesses one of the most equable and agreeable climates of the continent. Occupying as it does a situation between the temperate and tropical regions, it enjoys exemption from the frosts and sudden changes of the one and the excessive heat of the other. The mercury, however, sometimes falls to the freezing-point, and great damage is done to the orange planta-

tions. The winter climate of the Gulf coast is more rigorous than that of the Atlantic. The seasons partake of the tropical character, winter being distinguishable by copious rains. Statistics show the State to be one of the healthiest, if not the healthiest, of the U. States, and its resident population is largely increased in the winter months by invalids from the North, seeking a more genial clime. Jacksonville, St. Augustine, and Key West are preferred by this class of visitors, who are every year becoming more numerous. The mean winter temperature as observed at Key West was slightly less than that of Havana; while for the months from July to November it was about the same. Besides the advantage of its climate, the semi-tropical character of *F.* offers a grateful and striking change of scene to the health-seeker, who leaves the frozen streams of New England for a country teeming with luxuriant vegetation and strewn with flowers. — *Products.* The productions of *F.* are of an essentially tropical character; cotton, tobacco, rice, sugar-cane, arrow-root, hemp, flax, coffee, and the cocoanut flourish there. The climate is also favorable to the cultivation of the silk-worm and for the cochineal insect. Oranges, bananas, lemons, limes, olives, grapes, pineapples, grow abundantly, and are of exquisite flavor. Indian corn, sweet potatoes, beans, peas, and such products of a more northern climate as Irish potatoes, barley, buckwheat, hops, etc., are also raised. The cultivation and export of oranges and other fruits have grown to be a considerable source of wealth to the State; and the manufacture of cigars, especially at Key West, is becoming an important industry. The pasturage afforded by the savannas is excellent, cattle requiring little or no attention from their owners, and no housing in winter. Game and fish abound in every part of the State. Deer, wild turkeys, partridges, geese, ducks, and other small game are in all the forests and about all the lakes, rivers, and swamps; green turtle, oysters, sheep's-head, red fish, mullet, etc., are found on all the coasts, and fresh-water fish in all the inland waters. Magnificent sponges are gathered along the reefs, and form a considerable item of trade. Cotton, rice, sugar, tobacco, lumber, fish, and fruits may be considered the most valuable products. *F.* cotton is grown almost exclusively in the northern group of counties, but the State is capable of producing the celebrated sea-island variety, the cultivation of which was formerly confined to a few islands on the coasts of South Carolina and Georgia. Appalachicola, formerly a considerable shipping port for cotton, has been superseded by Fernandina on the Atlantic. The crop of 1877 is reported at 34,303 bales, of which 11,214 was sea-island; but it should be stated that this computation includes only shipments from *F.* outports, there being no data whence to estimate accurately the quantity going to ports out of the State by rail. The wool grown in *F.* is long stapled, of medium and coarse grades, little attention being as yet given to producing fine wools. In 1878 the flocks had increased to 56,500 head, yielding 200,000 lbs. of wool. East and South *F.* rely mainly upon fruit-culture. *F.* is said to be the only section of the Union where the orange can be grown to any extent with success. There is no fear of winter-killing *S.* of Pilatka. The quality of the fruit and the excellent condition in which it reaches the northern markets render this a most profitable crop. The forests of *F.* form no inconsiderable source of wealth. The live-oak, so valuable in ship-building,

abounds, also the other varieties of oak, swamp cypress, hickory, pine, magnolia, dogwood, and laurel. The *Palma Christi* (castor-oil bean) becomes here a large tree; on the islands and keys boxwood, satinwood, mastic, and lignum-vitæ grow abundantly. The pine is found from Cape Sable to near Indian River. In addition to fruit-bearing species, the pimento, coffee, pepper, clove, and other spice-trees and shrubs may be successfully cultivated. In 1878 the value of the live stock on farms was \$8,341,310. The number of horses was 22,200; mules and asses, 11,800; milch cows, 70,700; oxen and other cattle, 508,700; sheep, 50,500; swine, 130,000. — *Manufactures.* These are unimportant, and are chiefly confined to flour and grist mills, lumber-mills, and establishments for the manufacture of sugar and molasses. Agriculture and commerce are the chief resources of the State,—the export of its fibrous products, cereals, fruits, fish, live-oak and other timber, giving employment to a considerable tonnage. Among the mineral productions may be named amethyst, turquoise, lapis-lazuli, ochre, coal, and iron-ore.

*Trade.*—The coasting-trade employs many steamers and sailing craft, plying chiefly between Florida ports and Savannah, Baltimore, Philadelphia, and New York. Pensacola and Appalachicola are naturally points of shipment for Southern Alabama and Southwestern Georgia. The bulk of foreign merchandise reaches the State from northern ports instead of by direct importation. Key West shows much the largest tonnage of vessels entering or clearing, St. John's and Fernandina following in the order named. Ship-building is carried on at all the ports, the vessels usually being of small burthen, for coast traffic. — *Railways.* In 1878 there were only 481 m. of railway in *F.* The Jacksonville, Pensacola, and Mobile Railroad extends west from Jacksonville to Chattahoochee, and is the longest in the State. Lateral lines connect this line with the Georgia system by a branch from Live Oak due N. to Dupont, and with St. Mark's on the Gulf by a branch S. from Tallahassee. The Atlantic, Gulf, and West India Transit Company's line extends from Fernandina on the Atlantic to Cedar Keys on the Gulf, distance 155 m. The Pensacola and Louisville road extends from Pensacola N. to a junction with the Mobile and Montgomery (Alabama) Railroad, 45 m. The St. John's River line crosses from St. Augustine to Tocoi on the St. John's, 14 m. — *Seaports.* Notwithstanding the great extent of its seacoast, *F.* has few good harbors. Besides Key West, Pensacola, and Fernandina (separately given below), the principal ports are Appalachicola, St. Mark's, Cedar Keys, Tampa, and Charlotte on the Gulf, and St. Augustine on the Atlantic coast.

*Fernandina*, the cap. of Nassau Co., is situated on Amelia River and Amelia Island, about 185 m. E. by N. of Tallahassee. Its harbor is perfectly secure, and can receive the largest vessels. It is the eastern terminus of the Gulf Railroad, and its port has 12 vessels, with an aggregate tonnage of 2,185. In 1878, 130 vessels (tonnage, 80,697) entered, and 162 (tonnage, 92,750) cleared, the port. During the same year the imports amounted to \$22,778, while the exports (naval stores, lumber, etc.) amounted to \$268,443. Pop. about 3,000.

*Key West* is built on an island of the same name, 60 m. S. W. of Cape Sable, lat. 24° 32' N., and lon. 81° 52' W. The island, which is only about 4 m. long and 1 m. broad, was long the haunt of smugglers and pirates, but is now a busy

and thriving place, and one of the most important naval stations possessed by the U. States, on account of its commanding situation at the entrance of Florida Pass, the most frequented passage into the Gulf of Mexico, as well as its nearness to Havana, Kingston, and other important ports of the West Indies. The banks and reefs in the vicinity rendering the navigation difficult and dangerous, the U. States government has established at this place a fleet of 15 vessels, with crews of about 10 men each, for rendering assistance to vessels in distress. Key West is also the seat of an admiralty court for

Fig. 136. — KEY WEST.

the adjudication of claims for salvage. It has an excellent harbor, with about 25 feet water, and possesses 142 vessels (tonnage, 6,100). In 1878, 188 vessels (tonnage, 194,970) entered, and 175 (tonnage, 194,059) cleared, the port. During the same year the imports (mostly tobacco leaf) amounted to \$674,563, and the exports (chiefly horned cattle, wheat flour, Indian corn, and bacon) were valued at \$627,837. Pop. about 5,000.

*Pensacola*, the cap. of Escambia Co., is on the W. shore of Pensacola Bay, about 180 m. of Tallahassee. Its harbor, with 21 feet of water on the bar, is one of the best in the Gulf of Mexico. The government has here a naval station and a marine hospital. The port has 104 vessels, with an aggregate tonnage of 10,199. Pensacola is the centre of trade for the whole area of territory embraced by Santa Rosa Sound, Choctawhatchee Bay and River, and the Escambia, Black Water, and Perdido Rivers, — a territory reaching on the N. and W. far into the State of Alabama. For the year 1878 there entered and cleared from the port 490 vessels, with a total tonnage of 261,037. The imports amounted to \$22,407. The exports, consisting of hewn, sawn, dressed, and undressed timber, oak, cedar, staves, barrels of rosin, cotton, flour, cotton seed, sticks of fustic, etc., reached \$2,063,512. Pensacola has also an important coast-wise trade with Baltimore, New York, and other U. States ports. Pop. about 3,000.

**Floriline**, a vegetable tooth-paste, consisting of a red, dry, rather hard mass, made from prepared chalk, 20 grammes; starch powder, 10 grammes; glycerine, 8 grammes; pellitory tincture, 3 grammes; peppermint-oil, 10 drops; and water, q. s., colored with Florentine lac.

**Florin**, a silver coin current in several countries of Europe, ranging in value from 40 to 50 cents

The English florin, first minted in 1849, and of which sixteen million pieces have been since put into circulation, is worth 2s., and was the first practical attempt at a decimal currency in Great Britain.

**Florist**, a dealer in flowers; one who grows and sells them.

**Floss**, fluid glass floating in a puddling-furnace.

**Floss-Silk** [Fr. *bourre de soie*, *filoselle*] is the name given to the portions of unravelled silk broken off in the filature of the cocoons, which is carded like cotton or wool, and spun into a soft coarse yarn or thread, for making bands, shawls, socks, and other common silk fabrics. The floss or fleuret, as first obtained, must be steeped in water, and then subjected to pressure, in order to extract the gummy matter, which renders it too harsh and short for the spinning-wheel. After being dried it is made still more pliant by working a little oil into it with the hands. It is now ready to be submitted to the carding-engine. It is spun upon the flax-wheel. Pretty fine fabrics of this material are now produced in Italy, France, and England. *Imp. duty*, 35 per cent.

**Flotilla**, a fleet, how large soever, composed of small vessels.

**Flotsam, Jetsam, and Ligan**. In order to constitute a legal wreck, the goods must come to land. If they continue at sea, the law distinguishes them by the foregoing uncouth and barbarous appellations: *flotsam* is when the goods continue swimming on the surface of the waves; *jetsam* is when they are sunk under the surface of the water; and *lagar* is when they are sunk, but tied to a cork or buoy to be found again. All three belong to the government, or its grantee, if no owner appear to claim within a year after they are taken possession of by the persons otherwise entitled to them.

**Flounce**, a loose appendage or trimming to the skirt or lower part of a lady's dress.

**Flounder**, a flat fish, the *Pleuronectes flesus*, common on our eastern coasts. Its flesh is very wholesome. — In shoemaking, a slicking-tool whose edge is used to stretch leather for a boot-front in a blocking-board.

**Flour** [Dutch, *bloem*; Fr. *fleur de farine*; Ger. *Feines Mehl*, *Semmelmehl*; It. *fiore*; Port. *flor da farinha*; Sp. *flor*] is the grain of wheat reduced to powder and separated from the outer husk or covering in which the seed is enveloped. The name is also applied to the grain of other cereals, and to the farinaceous seed of pulses similarly treated, and it is used generally to indicate any finely powdered dry substance; but when the term is employed without any qualification, it invariably means flour of WHEAT, under which name are given the commercial statistics of flour.

**Flour-Barrel**, a light cask made to hold flour, of which millions are made annually. So immense is the quantity of hoops wanted for making these barrels, that, besides those produced in the country, they are largely imported from Canada, chiefly through the port of Rochester. — The American barrel of flour weighs 196 lbs.

**Flour-Dredge**, a tin for sprinkling flour.

**Flour-Dresser**, a cylinder for dressing flour, instead of passing it through bolting-cloths.

**Flour-Mill**. The ordinary *F.-M.* of the present day is a structure of comparatively few essential parts; but in the arrangement and mounting of these the greatest amount of mechanical skill and experience has been exercised, and the accessories of the mill have been elaborated with much care, with the view of saving manual labor and perfecting the processes and results. Fully to appreciate

the various processes of modern milling, it is necessary to bear in mind, not only that the wheat as delivered at the mill is dusty and mixed with sand and other refuse, but that it contains many light grains and seeds of foreign substances, which might be deleterious, and would certainly interfere with the appearance of the finished flour. Again, the structure of the wheat-grain itself must not be overlooked. A grain of wheat is not a seed, but a fruit, consisting of a pericarp, or outer envelope, tightly adherent to its contained single seed. The envelope consists of several layers of ligneous tissue, within which are the embryo and a peculiar fermentive nitrogeous principle termed cerealine, and finally a central mass of thin cells filled with a white powdery substance largely composed of starch granules. The object of ordinary milling is to grind as perfectly as possible, without breaking the minute granules, the central substance of the grain, and to separate it from the embryo and outer husks, the former constituting the flour and the latter the bran of the miller. Whole wheaten flour, on the other hand, consists of the entire grain ground up to a uniform mass. The machines and processes by which flour is prepared are very numerous, and are diverse in character; and it must further be said that, at the present moment, the whole industry is in a peculiarly unsettled and transitory state. The system which has prevailed in the U. States hitherto is what is known as ordinary or flat grinding with millstones; but in the mean time a strong tendency is developing in favor of the use, either partially or entirely, of granulating or high milling, and of some of the various systems of roller grinding which have been introduced. In Hungary and Austria the system of high milling prevails, in which the action of the millstones consists more in granulating than grinding; and in connection with that system of milling the use of rollers is a prominent feature. To a limited extent also the principle of the disintegrator has been brought into operation, in which the grain is broken by the violent impact of studs or projections revolving in opposite directions with enormous velocity. Thus we have these various systems: (1) flat milling or grinding; (2) high milling or granulation; (3) roller milling or crushing; and (4) disintegrator milling or breaking.

**Flat or Ordinary Milling**. In the ordinary or flat millstone milling there are three main points to consider: (1) The cleaning and preparation of the wheat; (2) the grinding; and (3) the bolting or dressing of the ground products. The ordinary cleaning or screening apparatus through which the wheat, as received, passes, consists of a kind of cylindrical sieve of wire cloth, mounted in a sloping position, and having internal partitions so as to resemble an Archimedean screw. When the apparatus is set in motion, the grain, fed in at its upper end, tumbles from one division into another, thereby being freed from small refuse and sand, and as it issues at the lower extremity is subjected to a fan blast. For cleaning grain there are other kinds of apparatus, in which the principle of aspiration, or drawing currents of air through the grain, is now extensively employed, the most frequently used being Child's aspirator. A further cleaning is sometimes given by Child's decorticator, an implement which can be adjusted at will, for simply rubbing and scouring the grain, or for removing the thin bran and germ previous to the operation of grinding. The "Victor" brush-machine is a recently introduced and highly approved apparatus for polishing wheat, its peculiar feature being that the opposed brushes are constructed and worked in such a manner that they come in contact with every kernel of wheat in every conceivable position, and with as much force as the miller chooses to use, thus polishing it on the end better than any other machine can do, and this not only on one pair of brushes, but on several. The prepared grain is next conveyed to the grinding apparatus, and here it may be said that, in moving the grain or flour horizontally, Archimedean screws working within an inclosed casing are employed, while in lifting from one floor to another, small boxes mounted on an endless band worked over pulleys and

similarly encased are used. The grinding machinery consists, first, of a bin containing the grain to be ground, from which it passes by a spout to the hopper, whence it is delivered by a feeding adjustment to the stones. These constitute the distinctive feature of the entire mill, and upon their condition and delicate adjustment the whole success of the milling operation turns. They consist of two flat cylindrical masses enclosed within a wooden or sheet-metal case, the lower or *bed-stone* being permanently fixed, while the upper or *runner* is accurately pivoted and balanced over it. The average size of millstones is about 4 feet 2 inches in diameter by 12 inches in thickness, and they are made of a hard but cellular silicious stone called *buhr-stone*, the best qualities of which are obtained from La Ferte-sous-Jouarre, Department of Seine-et-Marne, France. Millstones are generally built up of segments, bound together around the circumference by an iron hoop, and backed with plaster of Paris. The bed-stone is dressed to a perfectly flat plane surface, and a series of grooves or shallow depressions are cut in it. The grooves on both are made to correspond exactly, so that when the one is rotated over the other the sharp edges of the grooves, meeting each other, operate like a rough pair of scissors, and thus the effect of the stones on grain submitted to their action is at once that of cutting, squeezing, and crushing. The dressing and grooving of millstones is generally done by hand-picking, but sometimes black amorphous diamonds (carbonado) are used, and emery-wheel dressers have likewise been suggested. The upper stone, or runner, is set in motion by a spindle on which it is mounted, which passes up through the centre of the bed-stone, and there are screws and other appliances for adjusting and balancing the stone. Further, provision is made within the stone case for passing through air to prevent too high a heat being developed in the grinding operation; and sweepers for conveying the flour to the meal spout are also provided. The ground meal delivered by the spout is carried forward in a conveyor or creeper-box, by means of an Archimedeal screw, to the elevators, by which it is lifted to an upper floor, to the bolting or flour-dressing machine. The form in which this apparatus was formerly employed consisted of a cylinder mounted on an inclined plane, and covered externally with wire cloth of different degrees of fineness, the finest being at the upper part of the cylinder, where the meal is admitted. Within the cylinder, which was stationary, a circular brush revolved, by which the meal was pressed against the wire cloth, and at the same time carried gradually towards the lower extremity, sifting out as it proceeded the mill products into different grades of fineness, and finally delivering the coarse bran at the extremity of the cylinder. For the operation of bolting or dressing, hexagonal or octagonal cylinders, about 3 feet in diameter and from 20 to 25 feet long are now commonly employed. These are mounted horizontally on a spindle for revolving, and externally they are covered with silk of different degrees of fineness, whence they are called *silks*, or *silk-dressers*. Rotating arms or other devices for carrying the meal gradually forward as the apparatus revolves are fixed within the cylinders, and there is also an arrangement of beaters which gives the segments of cloth a sharp tap, and thereby facilitates the sifting action of the apparatus. Like all other mill machines, the modifications of the silk dresser are numerous. Mill products are differently assorted and classified in various localities and different mills, — some distinguishing many qualities of flour and bran, and others making only three or four divisions. (See WHEAT.) The following (from Church's *Food*) may be taken as a fair average representation of the product of 100 lbs. of good white wheat. —

Flour ...	1. Finest flour .....	42 lbs.
	2. Seconds flour .....	14 "
	3. Biscuit flour .....	9 "
Midlings.	4. Tails, or tailings .....	3 "
	5. Midlings, or fine sharps .....	8 "
	6. Coarse sharps .....	3 "
Bran....	7. Fine pollard .....	3 "
	8. Coarse pollard .....	6 "
	9. Long bran .....	3 "
	Loss by evaporation, etc.....	5 "

An additional proportion of fine flour is obtained by dressing and remilling tailings and midlings, and the purification and regrinding of these products have now become of much consequence in connection with the changed systems of milling rapidly coming into use. A great variety of midlings purifying machines have been introduced and eagerly pushed within the last few years, showing that this branch of economic milling is now receiving great attention.

*The Hungarian System, or High Milling.* The object of the low or flat milling process is to produce at one grinding operation as large a proportion of good finished flour as possible. In high milling, on the other hand, the stones are kept so far apart that grain is merely bruised in the first operation, and by a series of such grindings or bruising, alternated with elaborate sifting, the bran and all the outer envelopes with the cerealin are detached, and a nucleus of very pure semolina only left. In this way a large proportion of very inferior branny flour is obtained in these early millings, and the proportion of exceedingly fine strong flour for which Austro-Hun-

garian millers are famous is comparatively small. It is only to the hard brittle wheats that the Hungarian system of milling is applicable, and the method is only practicable under circumstances where there is a demand for the two extreme qualities of mill product which result from the system. Within the last few years the Hungarian millers have very largely adopted the roller mills, either to supplant entirely or to supplement stone grinding.

*Roller Mills.* In this form of mill a pair of horizontal rollers rotate face to face, and the grain or other material is submitted to their action by passing between them. The nature of that action varies according to the modification of roller surfaces, the closeness of the rollers to each other, and the equal or differential rate at which they revolve. Rollers of metal, either steel or chilled iron, having a toothed surface, revolving at different rates of speed and at definite distances apart, have a cutting action on the grain submitted to them. Such rollers are employed in the Buchholz system for reducing hulled wheat to the condition of semolina, and a similar arrangement is employed in the machine of Ganz & Co., of Buda-Pesth. Fig. 197 shows a section of the face of a pair of such rollers, where B, revolving slowly, serves as a holder for the grain, which is cut by the sharp edges of A, revolving at a speed three times greater than B. Smooth surface rollers are mounted to press hard against each other, and are made in some cases of polished chilled metal; and in other instances cylinders of porcelain are employed. Their principal function is for the reduction of purified middlings and semolina, and when no differential motion is given the action is simply that of squeezing; but when the opposing rollers revolve at different rates of speed a grinding effect is further superadded. A roller mill which has met great and sudden public acceptance

Fig. 197. — SECTION OF TOOTHED ROLLERS.

Fig. 198. — WEGMANN'S ROLLER-MILL.

is that invented and patented by F. Wegmann, a miller of Naples. In Wegmann's mill (Fig. 198) porcelain rollers are employed, there being two pairs fed from opposite ends of one hopper in the machine figured. This machine possesses a self-acting pressure and a differential motion, but its most valua-

ble feature consists in the employment of porcelain for rollers, by which a surface at once exceedingly hard and slightly rough or porous is secured. It is claimed for these rollers that, acting on middlings, they produce, with less expenditure of power, more and better flour than can be obtained by either stones or metal rollers. The roller-mills, however, have not yet been long enough in operation in this country to enable any safe conclusion to be drawn as to their adaptability to American milling; but though the system originated only within the last few years, it has in the mean time practically superseded all other methods in the Austro-Hungarian districts, where milling is carried to greater perfection than in any other part of the world. To show the progress made in the introduction of roller-mills in England, it may be noted that, while in January, 1877, there was only one Wegmann's machine in operation, there were by the close of the year 350 in various mills throughout the country.

*The Disintegrator.* Under this name a form of machine was invented and introduced a few years ago by the late Thomas Carr for, among other purposes, the manufacture of flour. Carr's disintegrator consists of a pair of circular disks of metal set face to face, and studded with circles of projecting bars so arranged that the circles of bars on the one disk alternate with those of the other. The disks are mounted on the same centre, and so closely set to each other that the projecting bars of the one disk come quite close to the plane surface of the other; and they are enclosed with an external casing into the centre of which a spout passes by which the grain is delivered into the machine. The disks are caused to rotate in opposite directions with great rapidity, making about 400 revolutions per minute, and as the outer circle of bars is 6 feet 10 inches from the centre, they move at a rate of 140 feet a second, or about 100 miles per hour. The grain in passing through the machine is struck by the oppositely revolving studs with enormous force,—a force which increases as the shattered grains approach the outer circles of studs,—and it is almost instantaneously reduced to a powder, which falls under the disks and is carried away by a spiral creeper. It is stated that one of these machines, 7 feet in diameter, is capable of doing the work of as many as 27 pairs of millstones, and they have been fully tested in the flour-mills of Gibson and Walker, Bonnington, near Edinburgh, Scotland, where two of them have been in operation for a period of seven years. Notwithstanding this success, however, the disintegrator has not, to this day, met with general acceptance in England as a flour-mill.

**Flour Paste.** See CEMENT (FLOUR).

**Flour-Sack,** a coarse bag for flour, holding usually 280 lbs.

**Flower-Basket,** a fancy stand or basket for holding flowers in a room.

**Flower-Pot,** an earthenware or china pot for holding flowering plants.

**Flowers,** the blossoms of plants. A large trade is carried on by florists in ornamental plants and cut flowers.—In chemistry, the fine mealy matter formed in the process of sublimation is called flowers, as flowers of sulphur, zinc, benjamin, etc.

*Artificial F.*, imitations of flowers and leaves, which form a common article in the dress of ladies. The beauty and value of these pleasing articles of personal decoration mainly depend upon the taste and ingenuity of the maker. The delicate fingers of woman, and her ready powers of imitation and invention, combined with her natural affection for the chaste and beautiful, have enabled her the more especially to excel in this manufacture. There are few branches of ornamental work used in the decoration of ladies' apparel which have more increased in importance than that of *A.-F.* making, in which, both in France and in the U. States, large numbers of workpeople are engaged. Not only has the trade itself greatly extended within the last few years, but the improvement in the manufacture is very marked, and the bouquets and wreaths used in the trimming of dresses may be almost said to rival nature, so truly and delicately are the individual flowers manipulated. *A.-F.* making is almost entirely done by hand, giving occupation principally to young women and children, the majority of whom work at home or in small shops. The numbers employed in New York are about 2,000,

of whom about 1,200 are under twenty years of age. In France the numbers are much larger; for ten years ago it was estimated that there were at least 2,000 shops where artificial flowers were made, and it is probable that now these have been increased to 3,000. It is not entirely woman's work, however, for men are employed, particularly in Paris, in cutting out the material for the flowers by a stamp machine, in which 16 or 20 folds are operated upon at once, the folds being colored green, blue, crimson, according to the flower which is to be imitated. Each piece is taken up separately by a girl armed with a pair of pincers, who, with one dexterous movement, moulds it, as it were, roughly into the shape of the flower, and then passes it on to another, who gives a more precise form to the petal. A third girl attaches each petal to a very fine wire, thread having been previously twisted round this wire to form the stalk; while the remaining operations consist in goffering the petals and leaves to give them a curl, and finally gumming or waxing them over, or dusting them with fine powdered glass or potato-flour to represent the bloom. The rapidity and accuracy with which these various processes are completed are very remarkable. A new style of *A. F.* has lately come into vogue, in France more especially, made by the "enamel process," in which a young girl sits by a jet of flame, holding in her hand a stick of prepared glass. A momentary application to the flame makes the end of the stick red hot, and while it is still in a pasty state the operator pulls out a short length, and immediately rolls it up into the form of the petal or leaf, and passes it on to the painter for the proper coloring. The remaining processes are similar to those of the ordinary *A. F.* These enamel flowers, though wondrously true and pretty, are more suited for room decoration than for dress. While apparently a light and pleasant work, *A.-F.* making is not one of the healthiest of our trades, partly for the reason that it is so often carried on in small household shops, where ventilation is of the scantiest. There is always a certain amount of dust and coloring matter flying about the room, which is more or less injurious, though the use of Scheele's green and sulphate of copper (verdigris blue) is almost discontinued, and with it a train of symptoms that usually accompany arsenical poisoning. Weak eyes are a common source of complaint, especially the form called asthenopia, which is particularly induced when white flowers are made by gaslight. In the manufacture of the flowers, the net cost is about three fifths of the whole for material, and the remaining two fifths for the labor.

*Imp. duty:* artificial and ornamental feathers and flowers, or parts thereof, of whatever material composed, 50 per cent.

**Fluate,** a salt of fluoric acid.

**Flue,** a smoke-duct or chimney. A *flue-boiler* is a steam-boiler having passages or flues surrounded by water for the conveyance of the gaseous products of combustion, in distinction from *tubes*, which hold water and are surrounded by fire.—Soft down or loose fur.

**Flue-Cleaner and Scraper,** a brush of wire or steel slips, or an implement with circular or spiral blades, to clean flue surfaces of steam-boilers.

**Fluid,** a liquid or gas; any body whose parts yield to the smallest pressure, and are moved among each other without any apparent sensible resistance. — Not solidified.

Fluids are of two distinctive kinds, elastic and non-elastic; the former are comprised under the general term *Pneumatics*,

and include all airs and gases; while the latter, which only include water and other aqueous fluids, are comprised under the general head of *Hydratics* and *Hydroaides*. The terms *elastic* and *non-elastic* are only used here in a relative sense, and not absolutely, as all fluids are elastic more or less, water being compressible, although offering resistance.

**Flukes**, the broad, projecting, triangular hooked plates at the extremity of the arms of an anchor, one or other of which, according as it is tilted, enters the anchorage ground as a hold-fast.

**Flume**, a water-channel; a stream or run for gold-washing.

**Flunkers**, persons who think they know all about buying or selling stocks, or who are induced by the persuasion of others to buy or sell; and, being ignorant of the snares of Wall Street, speedily lose their money. — *T. McElreath*.

**Fluor-Spar**, fluoride of calcium, a common mineral product, occurring in many places in this country. It is of various colors, wine, yellow, greenish, and violet-blue being the most common. It is abundant in Derbyshire, Eng., and is often called Derbyshire spar. Some of the varieties found there are beautifully banded, and are much prized for the manufacture of vases. It is also used for beads, brooch-stones, and other ornamental articles, but is difficult to work on account of its brittleness. Fluor-spar is used as a flux to promote the fusion of certain refractory minerals, — whence the name, from the Latin *fluo*, to flow.

**Fluoric Acid**, a corrosive liquid, prepared from fluor-spar, used for etching upon glass, roughing the shades of table-lamps, etc.

**Flush**, a carpenter's term, to express the continuance in the same planes of the surfaces of two contiguous bodies, irrespective of the direction of the fibre or grain. — Anything on the same level, as the deck of a ship, when it extends without break from stem to stern. — A stream of water suddenly thrown on, for cleansing, as in flushing a sewer. — A Scotch term for full, as affluent, flush of money.

**Flushing**. See HOLLAND.

**Flushing, North Shore, and Central R.R.** runs from Hunters Point, N. Y., to Babylon, N. Y., 34.34 m.; with branches from Woodside to Flushing, 3.81 m.; Whitestone Junction to Whitestone, 3.89 m.; Flushing to Great Neck, 6.87 m.; Garden City to Hempstead, 1.40 m.; and Bethpage Junction to Bethpage, 1.82 m. This Co., whose offices are in Long Island City, was organized in 1874 by the consolidation of the Flushing and Northside, the Central of Long Island, the Central of Long Island Extension, the North Shore, Whitestone, and Westchester, the North Shore and Port Washington, and the Roslyn and Huntington R.R. Cos., and in 1876 the road and branches were leased to the Long Island R.R. Co. *Financial Statement*, 1878: Cap. stock (authorized \$2,500,000) paid in, \$814,925; funded debt, \$3,155,182.86, of which details as follows. — North Shore R.R. 1st mortgage 7% 20-year bonds, payable 1885, \$125,000; ditto 2d mortgage 7% 20-year bonds, payable 1885, \$24,000; Flushing and North Shore R.R. 1st mortgage 7% 20-year bonds, payable 1889, \$800,000; ditto 2d mortgage 7% 20-year bonds, payable 1900, \$400,000; Central of Long Island R.R. 1st mortgage 7% 30-year bonds, payable 1902, \$1,000,000; ditto extra 1st mortgage 7% 30-year bonds, payable 1903, \$200,000; North Shore, Whitestone, and Westchester R.R. 1st mortgage 7% 20-year bonds, payable 1893, \$93,000; New York and Flushing 1st mortgage 7% 20-year bonds, payable 1880, \$25,000; consolidation mortgage 7% bonds, \$488,183.

**Flushings**, a kind of heavy and coarse woollen cloth made in lengths of 48 to 55 yards, also called *short-ends* in England.

**Flute**, a wind instrument which in a variety of forms (Fig. 139) has been in constant use from the earliest ages. In its primitive state the flute was played like the modern flageolet, with a mouthpiece at the upper end; and from the shape of this mouthpiece, which resembled the beak of a bird, it received the name of *flûte à bec*. In this form, with slight alterations, it continued until the beginning of the last century, when it was gradually superseded by the *flauto traverso*, or transverse flute, so called from its being blown by an oval-shaped hole in the side, and consequently held in a horizontal position. At its introduction this instrument was about 18 inches in length, and had but one key. Even in this state it was a great improvement on the old *flûte à bec*. Shortly

FIG. 139. — FLUTE OF ANCIENT EGYPT.

after a movable head-joint was invented, its length being increased, and more keys added, some flutes at the present time having more than a dozen keys, and few less than six. By means of these they are enabled to execute any music, however chromatic, if within their compass, which extends from C below the treble to C in altissimo. Some few will go four notes lower, and an experienced player will reach E flat in altissimo. The *piccolo*, or octave flute, the E flat or tierce, the D flat or *minor ninth* (transposing piccolo), the *flûte d'amour*, a minor third below the ordinary instrument, — are all varieties of the *flauto traverso*.

**Fluted**, grooved, furrowed, or channelled.

**Flutina**, a musical instrument of the concertina description.

**Fluting**, a piping or frill ornament to a lady's cap or dress. — One of the hollow channels cut in the shafts of columns. — One of the longitudinal grooves in a screw-tap, giving cutting-edges to the thread.

**Fluting-Iron**, a goffering iron.

**Fluting-Machine**, a machine having a pair of rollers, each one having projections which enter the interdigital spaces of the other.

**Flutter-Wheel**, a peculiar kind of wheel to a water-mill, which being placed at the bottom of a chute, receives the impact of the head of water in the chute and penstock.

**Flux**, any substance used to cause the fusion and reduction of earths or metallic ores by heat. White flux is the residuum of the deliquation in a red-hot crucible of a mixture of two parts of nitre and one of cream of tartar. It is in fact merely a carbonate of potash. Black flux is obtained when equal parts of nitre and tartar are deliquated. It owes its color to the carbonaceous matter of the tartaric acid, which remains unconsumed, the quantity of nitre being too small for that purpose. The presence of the charcoal renders this preparation a convenient flux for reducing calcined or oxidized ores to the metallic state. Limestone, fluor-spar, borax, and several earthy

or metallic oxides are employed as fluxes in metallurgy.

**Fly**, that part of a ship's flag which extends from the union to the extreme end. — That part of the machinery of a printing-press which withdraws the sheet, and lays it aside after the impression is made. — The compass-card on which the 32 points are drawn, and to which the needle is attached underneath. — In weaving, a shuttle driven through the shed by a blow or jerk. — In horology, a regulating device used in the striking-parts of clocks and watches, to control the rate of speed. See **FLY-WHEEL**.

**Fly-Boat**, a long, narrow boat used on canals; also a larger class of Dutch vessel, flat-bottomed, of several hundred tons.

**Flyer**, in weaving, a contrivance with arms which revolves around the bobbin in the *bobbin and fly frame*, or the *throstle frame*, which machines draw and twist the *sliver* into a *roving*, or the latter into yarn. — *E. H. Knight*.

**Fly-Fishing**, trolling in streams with a rod and line, and artificial flies.

**Fly-Flapper**, a fan or other instrument for keeping off flies.

**Flying-Bridge**, a temporary bridge.

**Fly-Leaf**, a spare blank-leaf in a bound book.

**Fly-Press**, a screw-press deriving its power from weighted arms, swinging in a horizontal plane, as in embossing and die presses.

**Fly-Powder**, an insect-destroying powder.

**Fly-Shuttle**, the shuttle impelled by the weaver.

**Fly-Wheel**, a wheel with a heavy rim (Fig. 200), placed on the shaft of any machinery put in motion by any irregular and intermitting force, for the purpose of rendering the motion equal and regular by means of its momentum. The rim of a fly-wheel, after a few revolutions, acquires a

Fig. 200. — FLY-WHEEL.

momentum sufficient to cause it to revolve with a velocity depending upon the resistance of the machinery. In all cases where a rotary motion is to be obtained from a reciprocating one by means of a crank, a fly-wheel is necessary to continue the motion at those two points of the revolution in which the crank lies in the direction in which the moving force acts. The momentum acquired by the fly-wheel urges the crank forward in the direction in which it was previously moving, and continues the rotation, thus making the motion equal and uniform.

**Foal**, the young of the horse kind; a colt or filly.

**Foam-Cock**, in a steam-engine, a cock at the water-level to blow off scum.

**F. O. B.**, free on board. A bill or invoice, f. o. b., includes the transportation on shipboard, and all the shipping expenses.

**Fob**, to cheat, defraud, or impose upon. — A little pocket for a watch.

**Focimeter**, in photography, an instrument, of which there are several kinds, to assist in focusing an object in or before a camera.

**Focus**, the point where the rays meet or converge, after passing through a convex glass. — A centre. — A hearth or fireplace.

**Focusing-Glass**, in photography, a glass used for magnifying the image on the ground-glass in the camera, to enable the operator to get it in better focus. — *E. H. Knight*.

**Fodder**, a general name for the dry food given to cattle, or stored for the winter. — A weight by which lead is sold in England, varying from 19½ to 23 cwt.

**Foglietta**, an Italian liquid measure varying from half a pint to a pint.

**Fog-Signal**, a detonating powder placed on a railroad track, which, when the engine passes over the rails, explodes with a loud report, and gives warning to the driver of danger, etc.

**Fog-Trumpet**, a horn or trumpet fixed on a vessel, a spar, etc., and blown by steam or any mechanical means, or by the wind, as a warning to mariners.

**Foil**, a thin leaf of polished metal, placed under precious stones and pastes, to heighten their brilliancy, or to vary the effect. Foils were formerly made of copper, timed copper, tin, and silvered copper, but the last is the one wholly used for superior work at the present day. Foils are of two descriptions: white, for diamonds and mock diamonds; and colored, for the colored gems. The latter are prepared by varnishing or lacquering the former. By their judicious use the color of a stone may often be modified and improved. Thus, by placing a yellow foil under a green stone that turns too much on the blue, or a red one under a stone turning too much on the crimson, the hues will be brightened and enriched in proportion. — An amalgam of quicksilver and tin at the back of a looking-glass. — A guarded sword and weapon for fencing.

**Foil-Stone**, an imitation jewel.

**Foire** [Fr.], a stated market in a town or city.

**Folding**, the operation of doubling one part of a substance over another. — Putting sheets of printed matter in order for binding. — In agriculture, penning sheep or cattle on land to feed and manure.

**Folding-Chair**, a chair which is collapsible for carriage or stowage.

**Folding-Door**, a pair of doors hung from opposite sides of the aperture, and meeting midway of the passage. — *E. H. Knight*.

**Folding-Machine**, a machine which delivers newspapers or printed book-work folded.

**Folding-Net**, a net for trapping small birds.

**Folding-Screen**, an upright portable screen, in several leaves or parts, which shuts up, and can be put away when not in use.

**Folding-Stool**, a portable or camp stool.

**Fold-Yard**, an enclosure for keeping cattle.

**Fole**, a leather bottle used in Spain.

**Folio** [Lat. *folium*, a leaf], in account-books, signifies page. Thus folio 7 — written abridgedly fo. 7 — denotes the seventh page; Folio recto, or F<sup>o</sup> R<sup>o</sup>,

signifies the first page; Folio verso, or  $F^o V^o$ , the second page of a leaf. A book in folio, or simply a folio, is that where the sheet is only folded in two, each leaf making half a sheet.

**Folioing**, the operation of paging or marking a book.

**Fonda**, the Spanish name for an inn or tavern.

**Fondique**, a hall for merchants; an exchange; a customs warehouse in Spain.

**Fong**, a coin current in Siam, the eighth of a tical, and worth about 8 cents.

**Font**, a stone basin or vessel in a church, for holding water for the purposes of baptism. — A complete assortment of a particular set of printing-type (also written *Fount*).

**Pontange** [Fr.], a knot of ribbons on the top of a head-dress.

**Foo-chow**. See CHINA.

**Food**, anything which feeds or promotes the natural growth of organic bodies, by supplying them with materials which, by assimilation, may be converted into the substances of which they are composed; or which, by its decomposition or slow combustion, maintains the temperature, or some other essential condition of life, at the proper standard. The numerous articles employed as food are all compounds; and in many cases they consist of mechanical mixtures or chemical combinations of two or more compounds. Organized matter, or that which has possessed either animal or vegetable life, or which has been produced by living organs, seems to be alone capable of assimilation, to any extent, by the animal system; and hence it is from the organic kingdom that our aliments are necessarily derived. Water, iron, earthy phosphates, chloride of sodium, and other salts, which form the inorganic constituents of the body, though not of themselves nourishing, are also assimilated when taken in conjunction with organic aliments, and then contribute essentially to nutrition. In the animal and vegetable substances employed as food these inorganic compounds are provided in small but sufficient quantities to meet the requirements of the healthy body, and in this state of combination alone can they be regarded in the light of aliments. A complete consideration of this subject embraces, not only all the substances used as food, but also those things which when taken with them improve their flavor, promote their digestion, and render them more wholesome and nutritive; and also their preparation for the table in its various relations with health and disease.

**Foolscap**, a long folio writing-paper, about  $13\frac{1}{2}$  by  $16\frac{1}{2}$  inches; a foolscap millboard is  $18\frac{1}{2}$  by  $14\frac{1}{2}$  inches.

**Foot**, a linear measure of 12 inches, or the third part of a yard. It also expresses surface and solidity. A square foot is the same measure both in length and breadth, containing  $12 \times 12 = 144$  square or superficial inches. A cubic or solid foot is the same measure in all directions, or 12 inches long, broad, and deep, containing  $12 \times 12 = 144 \times 12 = 1728$  cubic inches to the solid or cubic foot. — The bottom of anything, as of a shoe or stocking — The rest or support on which a machine or anything heavy stands. — To sum up, as the items of an account; to pay the expenses, as to foot the bill.

**Foot-Ball**, a large ball to be kicked about.

**Foot-Bath**, a pan in which to wash the feet.

**Foot-Board**, a support for the feet in a boat, etc., or at a workman's bench.

**Footing**, the total sum of a column of figures; the art of adding up such column. — The finer de-

tached fragments of the Tenks, or refuse whale-blubber, not wholly deprived of oil. — *To pay footing*, to pay a fee on first doing anything, as working at a trade or in a ship.

**Foot-Iron**, a carriage-step.

**Foot-Key**, an organ-pedal.

**Footlight**, a light on the front of a stage.

**Footman**, a man-servant. — An iron or brass stand with feet, or with a hook, for keeping anything warm before a fire.

**Foot-Plate**, the platform of a locomotive, on which the driver and fireman stand.

**Foot-Rope**, a rope stretched loosely along a ship's yard, for the seamen to stand on in furling the sails.

**Foot-Rule**, a twelve-inch measuring-stick

**Foots**, refuse or sediment, as at the bottom of a sugar or oil cask, etc.

**Foot-Scraper**, an iron scraper at an entrance door, to remove the dirt from the feet before entering.

**Footstall**, the stirrup of a woman's saddle.

**Footstep**, an inclined plane under a hand printing-press.

**Foot-Stick**, in printing, a wedge-shaped implement placed against the foot of a page in locking up the form, and between which and the chase the *quoins* are driven in.

**Footstool**, a small cushion or stool to rest the foot upon.

**Foot-Valve**. The lower valve between the condenser and air-pump.

**Foot-Waling**, the inside planks or lining of a vessel over the floor-timbers and below the lower deck.

**Foot-Warmer**, a heated stool for the feet. — A chafing-dish.

**Forage**, provender, or food, suited for horses and domestic cattle, as hay, straw, beans, grass, clover, etc.

**Force-Majeure**, a French commercial term for unavoidable accidents in the transport of goods, from superior force, the act of God, etc.

**Force-Pump**, a pump which delivers the water under pressure. In this kind of pump (Fig. 201), the piston, A, has no valve, but there is a valve, B, opening upwards at the bottom of the cylinder. Immediately above this valve, in the side of the cylinder, there is another valve, C, opening outwards into a tube, D, which is bent upwards to the height at which the water is to be delivered. On raising the piston, the valve in the bottom of the pump opens, and the water is pressed up into the cylinder, on the principle of the suction-pump. On pressing down the piston, the lower valve closes and the upper one opens, and the water is forced up the tube. When the piston is raised again, the upper valve shuts, retaining the water, and the

Fig. 201. — FORCE-PUMP.

lower valve opens. The same process is repeated, and the water is thrown out at every descent of the piston.

**Forceps**, tweezers, or metal holders of various kinds. — Surgical instruments used in midwifery, and for other purposes.

**Forcing**, a method of producing fruit, flowers, and vegetables, before their ordinary season of maturity, by artificial heat. — The process of fining wines, so as to render them fit for immediate draught.

**Forcing-House**, a hothouse.

**Forcing-Pit**, an enclosed hotbed or frame with a glass roof, containing a fermenting mass of dung for accelerating the growth of plants, etc.

**Ford**, the most shallow part of a stream or frith, which may be passed through on foot by wading, or crossed on horseback.

**Fore**, a maritime term for anything near, or pertaining to, the bow or stem, the forward part of a ship; as foremast, forefoot, etc.

**Fore and Aft**, a seaman's term for "in the direction of the ship's length"; from head to stern.

**Fore-Cabin**, the cabin in the front part of a ship, which has inferior accommodation for passengers.

**Forecastle**, a short deck in the bow of a ship, above the upper deck, in advance of the foremast; the forward part of the ship under the deck, where the sailors live in merchant vessels.

**Forefoot**, a piece of wood at the foremost extremity of the keel of a ship.

**Foreganger**, a short piece of rope grafted on a harpoon, to which the line is bent.

**Foreign-going Ships**, vessels trading to ports beyond the limits of the U. States. The term, however, does not apply to vessels trading with the Dominion of Canada.

**Forelock**, a flat piece of iron driven through the end of a bolt to prevent its drawing.

**Foreman**, an overseer; a chief workman. — The president or spokesman of a jury. — An inferior seaman.

**Foremast**, the first or forward mast in a ship; that nearest the bow.

**Forepeak**, the place allotted to the crew in merchant-ships.

**Foreright**, coarse wheaten bread.

**Forerunner**, a piece of rag terminating the stray line of the log-line of a ship.

**Foresail**, the large lower square sail on the foremast of a ship; the first triangular sail before the mast of a sloop or cutter.

**Forest**, a great wood; ground covered with a natural growth of trees.

**Forester**, one connected with forests.

**Forest-Wool**, a coarse, brownish fibre obtained by boiling pine leaves in a solution of caustic alkali, and subjecting them to other chemical processes. This fibrous material, mixed with sheep's wool, is used in the manufacture of blankets; and forest-wool yarn is manufactured into jackets, drawers, etc.; the fibre is made in *Silesia*. — *T. McElrath*.

**Forestay**, the rope supporting the foremast of a ship.

**Foret** [*Fr.*], a gimlet, or drill.

**Fore-Tackle**, tackle on the foremast, and also tackle used for stowing the anchor.

**Foretop**, the platform erected at the head of the foremast.

**Foretop-Mast**, the mast erected over the foremast, and above which is fixed the foretop-gallant-mast.

**Foretopmen**, men stationed in the foretop, in

readiness to set or take in the smaller sails, and to keep the upper rigging in order.

**Forge**, and **Forging**. When iron has gone through the various processes of smelting, refining, puddling, shingling, etc., it is ready to be *forged* into some or other of the infinitely numerous and varied forms required in the practical arts. This forging is a combination of heating and hammering. The forge is the hearth or furnace where the heating takes place, movable, or fixed, as the case may be; and the hammer may be worked by muscular power, mechanical power, or steam and air power, according to the arrangements. Practically, the forging commences when the white-hot iron is subjected to the ponderous blows of the shingling hammer; but the term is usually applied to the later process. The larger operations of forging are those in which several pieces of iron are welded together into one by repeated blows at a white heat. Such is the mode of making crankshafts for steam-engines, and paddle-shafts for steamers, when masses are welded together to the collective weight of 20 tons or more. For smaller work bars are piled or fagoted around a central

Fig. 202. — PORTABLE FORGE.

rod, or fragments of scrap-iron are enveloped in an old piece of sheet-iron, and then hammered into one piece. In short, there is hardly a limit to the variety of modes in which many pieces of iron are hammered into one, or a single piece hammered into a particular form. The ordinary open forge, or smith's hearth, is well known. There is a hearth of brick-work, 5 or 6 feet square; one side is extended to a vertical wall leading to the chimney, the lower end of which terminates in a hood of stout plate-iron. The back wall of iron is perforated to receive the blast from the bellows, or blowing-machine. This is the larger kind of hearth. The smaller, used for cutlery and small forgings, is raised 2 or 3 feet from the ground, with a hearth about three feet square; or, if there are two fires under one hood, the hearth may be 6 feet by 3. There is a trough or compartment for water, another for coals, and an ash-pit under the arch; the anvil weighs from 2 to 4 cwt., and is raised 2 to 3 feet from the ground. There are many forms of *portable forge*. In one of these (Fig. 202) the hearth is supported on four iron legs; the bellows, under the hearth, are worked by a lever handle extending obliquely upwards, and force air up a tube to the level of the hearth.

When made portable, the bellows and frames are placed on the hearth; the pipe and the legs are packed on the top and sides of the bellows; the hearth and its side plates form a box to contain the various pieces; and a cover closes down over the whole. Various matters connected with the forge and forging will be found treated under **BELLOWS**, **BLOWING-MACHINE**, **CUTLERY MANUFACTURE**, **HOT-BLAST**, **IRON MANUFACTURE**, **STEAM-HAMMER**, etc.

**Forger**, in the cutlery-trade, one who forms or fashions a tool or implement from the bar or rod of steel.—One who counterfeits coins, or issues false documents.

**Forgery**, a fraudulent or counterfeit imitation or deception, practised in the making or uttering a false instrument, or by altering a note, check, or order, with a fraudulent intent. It may be committed not only as to a whole document, but as to part of one, *e. g.* by an alteration in the amount of a bill, whereby the person who has engaged for a certain sum is made to appear bound for a larger. It is in its effect on the rights of the parties to negotiable documents only that it is connected with the subject of this work. No man can be made liable by his signature being forged by another, though one may in such circumstances create a liability by acknowledging the signature as his own. In the general case, acceptance of a bill is an acknowledgment of the drawer's signature, which will make the acceptor fully liable to third parties. Acceptance is not, however, held to be an acknowledgment of an indorser's signature. Whoever pays a forged bill (whether a drawee, or a banker at whose house it is made payable) is presumed, also, to have admitted or guaranteed the signatures of the parties, and will not recover his money, unless he find out the *F.* immediately, before circumstances affecting the position of other parties have intervened, and send notice on the day on which he made payment. A person so paying will not have recourse on the party who appears, through means of *F.*, as drawer of an unaccepted or acceptor of an accepted bill. A party who pays for honor is under like liabilities should the name of the person he has so paid for have been forged. "Whoever," says Bayley, "pays a bill, should be satisfied that it is, in all its parts, genuine; if he be not, he will pay it at his peril, and will lose his remedy against the party on whose account he pays it." In the case of vitia-tions and alterations, this distinction has to be considered,—that where, through the carelessness of the original maker of the document, facilities have been left for alteration without detection (as where room is left for adding a word to the sum and thereby increasing it), he will be responsible for what appears on the face of the paper.

Fig. 203. — EGYPTIAN FORK.

**Fork**, an agricultural implement of great antiquity, being referred to in the Book of Judges, and represented on the Egyptian tombs at Thebes (Fig. 203). It is divided at the end into two or more points or prongs, and used for lifting, digging, carrying, or throwing. There are *F.* of dif-

ferent kinds, as the *digging-F.*, *dung-F.*, *grain-F.*, *hay-F.*, *pitch-F.*, etc.—The *table-F.*, for taking up food, is only about three centuries old. In ancient times, as is the practice still in the East, meat was commonly prepared as stews; or, if roasted, it was cut into small pieces by a carver, so as to be easily taken in mouthfuls by the guests, who used their fingers and a knife for the purpose. It certainly is a strange fact, that the use of any species of *F.* at table was quite unknown till the 15th century, and they were then known only in Italy, which has the merit of this invention. None of the sovereigns of England had *F.* till after the reign of Henry VIII.; all, high and low, used their fingers. The first royal personage in England who is known to have had a *F.* was Queen Elizabeth; but although several were presented to her, it remains doubtful whether she used them on ordinary occasions.

**Table-F.** Making differs from cutlery-work generally in requiring stamping. A rod of steel, heated at the forge, is fashioned into tang, shoulder, and shank, with a piece at one end beaten out flat for the *mood* or *mould*. This mood becomes the prongs; it is heated, and placed in a steel boss or die. An upper die is attached to the lower face of a heavy weight, and by allowing this weight to fall through a height of several feet, the prongs are stamped out of the mood by the cutting action of the die and counter-die, as well as the *boss*, or curved part, which connects the prongs with the shank. After a little filing, the *F.* is ready for grinding. This is done on a dry stone, and is very destructive to health. (See **GRINDING**) Wire-gauze shields for the mouth, and special ventilation of the grinding-rooms, are to some extent adopted; but the *F.*-grinders are too often a reckless body of men, regardless of health, earning large wages, and prone to the maxim of leading "a short life and a merry one." The finishing processes by laps, glaziers, and polishers (see **POLISHING**), require much ingenuity to reach all the curvatures and corners of the *F.*

**Fork-Chuck**, a short piece of steel which fits into one of the sockets or chucks of a lathe, used by wood-turners for carrying round the piece to be turned; it is flattened at the end like a chisel, but has a projecting centre-point, to prevent the wood from moving laterally.

**Forkstaff-Plane**, a joiner's plane for working convex cylindrical surfaces.

**Fork-Tail**, a salmon four years old.

**Forlon**, a Spanish chaise or carriage with four seats.

**Form**, shape.—A mould in which anything is wrought.—A mass of type, in pages or columns, ready for press.—The arrangement of newspaper columns or the pages of a book in an iron chase, for machinery or printing.—A long wooden bench.

**Former**, a shape around which an article is moulded, woven, wrapped, pasted, or otherwise constructed.

**Formic Acid**, an organic acid, obtained by oxidizing many organic substances, and found in the red ant. It is a burning liquid of an irritating odor. It is exceedingly corrosive, producing a sore if dropped upon the skin. It boils at 221°-5°, yielding an inflammable vapor, burning with a pale-blue flame. Sp. gr. at 32°, 1.222. It is readily distinguished from acetic acid, which in many points it resembles, by heating it with a little solution of oxide of silver or mercury; the metal is reduced, and precipitated in a pulverulent state, while carbonic acid is extricated. The odors of the two acids also vary.

**Formosa**. See **CHINA**.

**Formula**, in pharmacy and medicine, a short form of prescription; a recipe. By chemists the term is applied to a grouping of symbols, expressing the composition of a body; thus, HCl (standing for 1 atom of hydrogen united to 1 atom of chlorine) is the formula for hydrochloric acid.

**Forril**, lambskin parchment.

**Fort de France.** See MARTINIQUE.

**Fortin**, a dry measure at Constantinople; rather less than 4 bushels.

**Fort Wayne, Jackson, and Saginaw R.R.** runs from Jackson, Mich., to Fort Wayne, Ind., 100 m. This Co., whose offices are in Jackson, was formed by the consolidation in 1869 of the Jackson, Fort Wayne, and Cincinnati and the Fort Wayne, Jackson, and Saginaw R.R. Cos. The road was opened in 1870. *Financial statement*: Cap. stock, \$1,149,950; funded debt, \$2,000,000, consisting of 1st mortgage 20-year 7% bonds, \$1,500,000, payable in 1889, and 2d mortgage 8% 20-year bonds, \$500,000, payable in 1891.

**Fort Wayne, Muncie, and Cincinnati R.R.** runs from Fort Wayne, Ind., to Connorsville, Ind., a distance of 104.18 m. This Co., whose offices are in Fort Wayne, opened the road in 1870. *Financial statement*: Cap. stock, \$1,000,000; funded debt, \$2,745,000, as follows, — 1st mortgage, issued 1869, payable 1889, \$1,800,000, interest 7% (April and Oct.); 2d mortgage, issued 1871, payable 1896, \$500,000, interest 8% (April and Oct.); equipment mortgage, issued 1871, payable 1881, \$345,000, interest 8% (Jan. and July).

**Forward**, the forepart of a ship. — To send forward; to transmit, as a letter, a despatch, etc.

**Forwarder**, one who acts as agent for the owner in the transshipment, transmission, or forwarding of goods; a forwarding-merchant.

**Forwarding-Merchant**, one who receives and forwards goods to distant consignees, for which he receives a compensation from the owners, but who has no concern in the vessels or vehicles by which they are transported, and no interest in the freight; he is not a common carrier, but a warehouse man or agent, and is required to use only ordinary diligence in sending the merchandise by responsible persons and properly appointed conveyances.

**Fosset**, a small chest.

**Fossils**, petrified shells, animals, plants, etc.

**Fostel** (Scotch), a cask.

**Fother, Fodder**, in navigation, to draw a sail filled with oakum under a ship's bottom in order to stop a leak. — A cart-load. — A large quantity. — A weight for lead, ordinarily 2,184 lbs., or 8 pigs, but variable. See FODDER.

**Fotmal**, a commercial term for 70 lbs. of lead.

**Fou** [Scotch], a pitchfork; a firlo or bushel.

**Fouang**, a coin of Siam, the half of a mace, called by the natives phuani, worth 800 cowries; also a weight the 8th part of the tical, and equal to 29½ grains.

**Foudre**, a large cask or vessel used in France and Germany, and varying from 142 up to 654 gallons.

**Foul**, a sea-phrase that is used in distinction from clear, and implies entangled, embarrassed. Hence, *F.* anchor, when the cable is twisted round the stock and flukes; *F.* bottom, when a bay is covered with weeds, grass, shells, filth, and rocks. *F.* hawse means that the cables are turned round each other by the ship having swung the wrong way when moored. *F.* rope, a rope entangled and unfit for immediate use. *F.* water is water troubled, and rendered turbid by the ship's bottom rubbing on the ground. *F.* wind is used to express that the wind is unfavorable, or contrary to the ship's course, as opposed to large or fair.

**Foulard**, a kind of silk material for ladies' dresses, plain, dyed, and printed; a silk kerchief or cravat.

**Foul-Proof**, an uncorrected printed slip, before

the typographical and other errors have been rectified.

**Foundation**, the basis on which a superstructure rests, as a bridge or building.

**Foundation-Muslin**, an openwork gummed fabric, used for stiffening dresses and bonnets.

**Foundation-Stone**, the first or corner-stone of a building in large erections, usually laid in public and with some ceremony.

**Founder**, one who founds, establishes, or erects; one who lays a foundation; an originator; an endower. — A caster of metals. — The act of a ship's sinking.

**Founders-Dust**, charcoal-powder, and coal and coke dust ground fine, and sifted for casting purposes in foundries.

**Founding.** See CASTING.

**Foundry**, the place where masses of metal are melted and run into moulds.

**Fount.** See FONT.

Fig. 204. — AMERICAN SODA-FOUNTAIN.

**Fountain**, an artificial receptacle for water. — A machine by which water is spouted out, generally consisting of pipes or jets of water flowing from statues, vases, etc., in public squares, gardens, or private conservatories, etc. — An apparatus (Fig. 204) containing ice and a coil through which aerated water, known as "soda-water," is conducted from a copper vessel placed under the box to the nozzle, when it is drawn into glasses. *E. H. Knight.*

**Fourgon**, a tumbrel, or ammunition wagon. — A kind of French baggage-cart. — A fire-poker. — An oven-fork or coal-rake.

**Four-in-Hand**, a coach driven with four horses.

**Fourneau**, a stove, or kiln, in France.

**Fourpence**, an English silver coin (29½ grains), also known as a groat.

**Four-Poster**, a large square bedstead, with upright pillars at each corner, supporting a canopy or curtains.

**Fourth-Rate**, a gunboat carrying from 1 to 4 guns; formerly a vessel of war carrying from 50 to 70 guns.

**Fowl**, a very general name for the denizens of the poultry yard; but for the most part restricted to the cock and hen (*Gallus domesticus*), of which the breeds are now very numerous.

**Fowler**, one who pursues or traps wild fowl.

**Fowling-Piece**, a light long-barrelled gun.

**Fox**, a seaman's name for a kind of strand of two or more rope-yarns, twisted together. — To put new soles on boots. — A carnivorous animal (*Canis vulpes*). The skin of some of the Northern foxes forms an article of commerce. The most valuable are those of the black fox and silver fox, which are purchased for the Russian and Chinese markets. The red fox is that chiefly brought to market.

**Foxed**, timber or paper discolored by incipient decay.

**Foxglove**. See *DIGITALIS*.

**Fractional Currency**, notes issued by the U. States Government for the fractions of a dollar, to wit, 50, 25, 15, 10, and 5 cents. The issue of these notes was authorized by act of March 3, 1863; limited to \$50,000,000 by act of June 30, 1864; and discontinued in 1878. The total amount issued was \$49,102,660.27; the total amount outstanding on June 30, 1878, redeemable on presentation, was \$16,547,768.77. See *NATIONAL DEBT*.

**Fracture**, a severance; damage or injury done.

**Fragile**, brittle, easily broken, as glass, pottery, etc.

**Frail**, a package or basket made of rushes, in which dried fruit is occasionally imported, varying from 32 to 56 lbs. in weight.

**Fraise**, the French name for a strawberry.

**Frame**, a word of varied signification; the border or enclosure for a picture. — The wood-work in which panes of glass are placed for windows. — The outward work of doors or window-shutters, enclosing panels. — The strong work which supports the boiler and machinery on the axles of a locomotive engine. — A support for printers' cases of type. — A mould. — The ribs or stretchers for an umbrella or parasol. — The timbers or skeleton of a house or ship.

**Frame-Maker**, a name applied to several mechanical trades, etc., as a picture-frame maker, printers' frame maker, etc.

**Framework**, a term in the hosiery-trade for a hand process of weaving the woollen or cotton thread up into the knitted fabric.

**Framingham and Lowell R.R.** runs from Framingham to Lowell, Mass. This Co., whose offices are in Fitchburg, Mass., was chartered in 1870, and the road opened in 1871. It has been operated since Feb. 1879, by the Old Colony R.R. Co. *Financial Statement*: Cap. stock, \$512,000.00; funded debt, \$750,000, consisting of 1st mortgage 7% 20-year bonds, payable 1891, \$500,000; coupon 8% 10-year notes, payable 1882, \$150,000; coupon 8% 10-year notes, payable 1883, \$100,000.

**Franc**, a French silver coin of the value of 18½ cents by mint valuation. The franc is the monetary unit of France, and all other coins, whether copper, silver, or gold, are its mere divisions and multiples, by whatever name they may be called.

**France**, an important republic of W. Europe, extending from lat. 43° to 51° N., and from lon. 7° 35' to 1° 43' W. The boundaries of France are: N., the English Channel (*Manche*), the Straits of Dover (*Passé-Calais*), Belgium, and Luxembourg; E., Germany (Alsace-Lorraine), Switzerland, and Italy; S., the Mediterranean and Spain; W., the Atlantic Ocean. From N. to S. its length is about 576 m., measured from Dunkirk to the Col of Falguères; its breadth from E. to W. is about 494 m., from Mont Donon to Cape Saint-Mathieu at the extremity of Brittany, which projects into the Atlantic like a wedge, and without which *F.* would approach in form to a square; and its superficial extent, including Corsica and the small islands on the coasts, is 204,147 sq. m. Though in point of extent of coast and ready access to the sea *F.* is far inferior to Great Britain and Ireland, it is, on the other hand, more fortunate in these respects than the vast inland territories of Austria and Russia, — its coast line extending 325 m. on the Mediterranean, 572 m. on the North Sea, the Straits of Dover, and the English Channel, and 584 on the Atlantic. The country has the advantage likewise of being separated from its neighbors by natural barriers of great strength, the Pyrenees forming a powerful bulwark on the S. W., the Alps on the S. E., and the Jura and the Vosges mountains on the E. The boundary line on the side of Belgium is the only one which nature has left unprotected. *F.* enjoys, upon the whole, greater natural advantages than any other country in Europe. Her territory is above a half larger than that of Great Britain and Ireland, and both her soil and climate are better, — there being a greater amount of summer heat to bring the fruits of the earth to perfection. She has a greater proportion of arable land than any of her neighbors; the natural means of communication throughout her provinces are abundant and easy; she is well provided with all the useful metals except tin, and is better supplied with coal than any other country of Europe but Britain. Even during the distractions of her great Revolution, though her foreign trade was annihilated, her agriculture and manufactures were extended and improved, her population was increased, and its condition ameliorated. In addition to the vegetable productions that grow in England, the climate of *F.* enables her to raise vines, olives, mulberries, and chestnuts. Wine and olive-oil are two of her most valuable productions. The cotton-trade has assumed great importance in the northern and eastern provinces; and Lyons has been long famous as the centre of the silk-trade of Europe, — a branch of manufacture that has been brought to great perfection in that city. The manufactures of woollen cloth, flax, hemp, and iron are also very extensive. The government always maintains a large standing army, amounting in 1879, on the peace establishment, to 496,442 men and 124,279 horses. Her armed fleet on service is superior in number of ships to that of Britain, with about 60,000 men. — The present constitution of *F.*, voted by the National Assembly, elected in 1871, bears date February 25, 1875. It vests the legislative power in an assembly of two houses, the Chamber of Deputies and the Senate, and the executive in a chief magistrate called the President of the Republic. The Chamber of Deputies is elected by universal suffrage. There were 9,962,329 "electeurs politiques," or persons possessing votes, at the general election of 1878. The only requisite to be an elector is to be possessed of citizenship, and to be of the age of

21 years, while the only requisite for a deputy is to be a citizen, and 25 years of age. There are 532 members in the Chamber of Deputies. The Senate is composed of 300 members, of whom 75 hold their seats for life, the vacancies being filled by the choice of the Senate. The remaining 225 seats are divided by lot into three classes of 75 each, one class going out at successive periods of three years. The election of these 225 senators is by an indirect process. In the first instance, the communes and municipalities of *F.* elect, by a majority of their members, a fixed number of "électeurs sénatoriaux," who in their turn, after a lapse of two months, meet together to choose the senators. The first meeting of the municipal councils for the choice of electors, under the constitution of 1875, was in October, 1878, and the first meeting of the electors, numbering 43,127, in January, 1879. No other qualification is required for a senator than to be a Frenchman and 40 years

1878 the expenses connected with the Senate were fixed at 3,865,600 francs, and those of the Chamber of Deputies at 6,521,000 francs, being a total of 10,386,600 francs, or \$2,077,320. The President of the Republic is chosen for seven years by the Senate and Chamber of Deputies voting together. He promulgates the laws passed by the parliament; he has the command of the land and sea forces, but cannot declare war without the advice of the Chambers; he makes treaties of peace, alliance, and commerce, nominates to all government offices, and has power to dissolve the Chamber of Deputies, with the sanction of the Senate. He receives a yearly salary of 600,000 francs, with an allowance of 162,400 francs for household expenses. The executive department of the government is administered by the President of the Republic and his cabinet council, consisting of nine ministers, viz.:—the minister of justice and keeper of the seals; the minister of foreign affairs; the min-

Fig. 205. — COLONNADE OF THE LOUVRE.

of age. The Senate and the Chamber of Deputies assemble every year on the second Tuesday in January, unless a previous summons is made by the President of the Republic, and they must remain in session at least five months every year. Both begin and finish their session at the same time. The President of the Republic pronounces the close of the session, and has the right of convoking the Chambers for an extraordinary meeting. He is bound to convolve them if the demand is made by one half of the number of members composing each Chamber. The President can adjourn the Chambers, but the adjournment cannot exceed the term of a month, nor occur more than twice in the same session. The Senate has conjointly with the Chamber of Deputies the right of initiating and framing laws. Nevertheless, financial laws must be first presented to and voted by the Chamber of Deputies. Both the Senators and the Deputies receive payment for their services at a fixed rate per diem. In the budget for

ister of the interior; the minister of finance; the minister of war; the minister of marine and colonies; the minister of public instruction, ecclesiastical affairs, and the fine-arts; the minister of agriculture and commerce; and the minister of public works; they are appointed by the President of the Republic, and are responsible to the Chamber. They receive a salary of 60,000 francs, and may live, if they choose, in the "hôtels" where the duties of their ministry are discharged.—Administratively, *F.* is divided into 87 *departments*, cut rather arbitrarily out of the territory of the provinces into which the country was divided prior to 1793. These departments are subdivided into 362 *arrondissements*, 2,865 *cantons*, and about 36,000 *communes*. Each department is administered by a *prefect* appointed by the President of the Republic, and each *arrondissement* by a *sub-prefect*. The prefects are divided into three classes, the salary being 35,000 francs for the first class, 24,000 for the second class, and

18,000 for the third class. The prefect of the Seine has 50,000 francs a year. The authority of each prefect is great in his own department: he can issue local decrees; he appoints and dismisses a number of agents who depend directly upon him; he is at the head of the police to maintain public order, and for this purpose can summon the military forces; he superintends the collection of taxes; he is in correspondence with all the subordinate functionaries in his department, to whom he transmits the orders and instructions of the ministers; in one word, he is the general agent of government, and the principal instrument of centralization in the state. He is assisted in his work by two bodies, the general council (*council général*), which is elected by universal suffrage, and the council of prefecture, which is nominated by the head of the executive power. The business of the council of prefecture is to decide all legal questions, and to advise the prefect, when asked to do so. The general councils assess the taxes, authorize the purchase, sale, or exchange of departmental property, superintend the management of the same, decide about new roads, railways, or canals, vote the budget for sanitary and charitable institutions belonging to the department, and give advice on every matter of local interest, political questions being strictly excluded. The law of Feb. 23, 1872, however, has invested them with great political importance; in case of the parliament being violently dissolved by a *coup d'état*, they must immediately assemble, and form a new parliament with their delegates, in order to oppose by all means the criminal attempt. As

the prefect in the department, so the sub-prefect, with a more limited authority, is the representative of the central power in the *arrondissement*. He is assisted, and to a certain extent controlled, in his work by the council of *arrondissement*,—an elective body to which each *canton* of the *arrondissement* sends one member. Except in that case, the *canton* is not an administrative division. The *commune* is the administrative unit in *F.* At its head is a mayor assisted by deputy-mayors (*adjoints*), the number of whom varies according to the population; *communes* of 2,500 inhabitants have one deputy-mayor; up to 10,000 inhabitants they have two, from 10,000 to 30,000 three, and one additional for every 20,000. The mayor has a double part to perform, as he represents both the central power and the *commune*; and often it is a difficult matter to avoid a conflict of duties. He is, besides, *officier de l'état civil*, or officer register of births, marriages, and deaths. The mayor and deputy-mayor are not salaried officials. In large towns they are nominated by the government, but they must always be chosen out of the *municipal council*, which is elected on the principle of universal suffrage, and has with regard to the *commune* much the same power and duties as the general council with regard to the department. The population of *F.*, which in 1801 was 27,349,003, was 30,905,788 in 1876, of whom 11,405,000 were living in towns. The following table shows the extent of each department, and the population according to the census returns of 1861, and of December 31, 1876.<sup>1</sup>

<sup>1</sup> After the cession of territory to Germany in 1871, a single department (Meurthe-et-Moselle) takes the place of two (Meurthe and Moselle), the Bas-Rhin disappears, and of the Haut-Rhin there remains only the territory of Belfort.

The increase of population in *F.* within the last century and a half has been comparatively less than in any other State of W. Europe. The natural increase, from the surplus of births over deaths, amounted, when at its highest, between the years 1820 and 1830, to not quite 280,000 per annum, and during part of the decennial period from 1850 to 1860, sank to 51,200 per annum. There was a slight recovery during the first half of the next decennial period, but in the year 1869 the surplus of births over deaths had again fallen to 84,206. In the following two years, 1870 and 1871, the deaths exceeded the births, the excess of deaths amounting to 103,394 in 1870, and to 444,889 in 1871. In the year 1872 there was again a surplus of 172,937 births, and the surplus continued in 1874 and 1875. The birth-rate per hundred inhabitants was 3.11 in 1827, and had fallen to 2.62 in 1868. It fell to 2.57 per cent in 1869, and to 2.26 per cent in 1871, and was 2.61 in 1873, and 2.64 in 1875, — a birth-rate lower than that of any other country in Europe. — The following table, compiled from the last official returns, gives the number of births, deaths, and marriages, with the surplus (+) or deficiency (—) of births over deaths in each of the fifteen years from 1862 to 1876.

Years.	Births.	Deaths.	Marriages.	Surplus (+) or deficiency (—) of Births over Deaths.
1872	995,167	812,978	303,514	+182,189
1873	1,012,794	844,917	301,376	+165,887
1874	1,005,830	830,334	299,579	+145,546
1875	1,005,753	921,837	293,393	+83,866
1876	1,001,258	834,573	302,136	+121,685
1877	1,007,515	835,387	300,333	+140,628
1878	934,140	922,093	311,225	+62,102
1879	948,523	874,320	303,482	+74,206
1870	943,515	1,045,909	223,705	—103,394
1871	823,121	1,271,010	252,476	—444,889
1872	965,901	793,064	352,754	+172,837
1873	945,314	841,559	321,233	+101,776
1874	954,652	781,703	313,113	+172,943
1875	950,975	845,032	305,427	+105,913
1876	936,632	834,074	291,336	+132,908

Not included under either the births or deaths of the above table are the *mort-nés*, or dead-born. The number of *mort-nés* was 37,778 in 1854, and gradually increasing, reached 44,630 in 1876. The births of 1877 consisted of 899,376 legitimate, and of 67,308 illegitimate, or *natural* children, the latter forming 7.12 per cent of the total. In the capital, represented by the department of the Seine, the proportion of illegitimate children was 25.21 in the year 1876. The proportion of male to female children born was 106 to 100 previous to 1840, but since the latter date the male preponderance has been gradually declining, and in 1876 had fallen to 105.2 to 100 for the whole of France, and to 102.1 to 100 for all Paris births. — The population of *F.*, like that of most other European countries, is agglomerating ever more in towns. In 1846 the rural population constituted 75.58 per cent of the total, and the urban 24.42 per cent; in 1856 the rural had fallen to 72.63, and the urban risen to 27.31 per cent; in 1868 the rural was 69.54, and the urban 30.46 per cent; and finally, at the census of 1876, it was found that the rural population constituted but 65.10, and the urban 34.90 per cent of the entire population. There is scarcely any emigration from *F.*, the only exodus that has taken place in recent years consisting in a movement of the Basques, in the department of the Hautes-Pyrénées,

to quit their country, in order to escape military service. In 1873 and 1874 there emigrated 12,000 Basques to South America, chiefly to the Argentine Republic and Uruguay. The stationary character of the mass of the pop. is shown also by there being little migration within the country. At the census of 1872 it was found that of the total of 33,102,921 individuals constituting the pop. of *F.*, 30,676,943 were born within the registration districts. Thus out of every 100 individuals but 15 had quitted their native commune and 85 lived where they were born. Almost the whole of the existing migration is that from the rural districts into the towns of *F.* The following table of the pop., arranged according to employments (exclusive of children and servants), is taken from the census of 1872.

	Men.	Women.	Total Number.
Agriculture.....	4,664,855	1,305,316	5,970,171

The surface of *F.* exhibits, in general, an advantageous succession of high and low ground. Less level than Poland, the North of Germany, or the greater part of European Russia, it is on the whole less mountainous than Spain or Italy. Passing over lofty ridges which form the frontier line of *F.* on the side of the Pyrenees, the Alps, the Jura, and the Vosges, and confining our attention to the interior, we find, throughout Flanders, Picardy, Normandy, and the countries to the N. and S. of the Loire, a level tract, diversified occasionally by hills, either insulated or in succession, but by none of the massy elevations entitled to the name of mountains. These we do not meet until reaching the S. of Champagne and N. of Burgundy, near the sources of the Meuse, the Moselle, the Saône, and the Seine. From this bleak quarter (lat.  $47^{\circ}$  and  $48^{\circ}$ ), a very long range of mountains proceeds from N. to S. in a direction parallel to the course, first of the Saône, and subsequently of the Rhône, until, on approaching the Mediterranean, they branch off to the S. W. and join the Pyrenees. Their greatest height is in Auvergne (about lat.  $45^{\circ}$ ), where this chain, or more properly a lateral branch of it, attains, at the mountains called Cantal and Puy-de-Dôme, an elevation of fully 6,355 feet, and has its highest ridge covered with snow during the greater part of the year. Another, but a much less lofty range, extends from Bordeaux to the S. E., a distance of 150 m., until it reaches the Pyrenees. The smaller chains are numerous in the E. and S. E. of the kingdom, — in Lorraine, the Nivernois, Dauphiné, Provence: also in part of the interior, particularly the Limousin and Guienne. They are interspersed with extensive plains, but, on the whole, the S. and E. of France are rugged and elevated tracts — *Rivers.* The course of the great rivers is easily connected with this view of the surface of the territory of *F.* The Moselle, the Meuse, the Marne, the Aube, the Seine, the Yonne, taking their rise on the N. side of the mountain chain, between lat.  $47^{\circ}$  and  $48^{\circ}$ , flow all to the N. or N. W., until reaching the sea or quitting the territory of *F.* From the S. slope of the same range proceed the Saône, the Doubs, and the Ain. These, along with many smaller streams, are all received by the Rhône, which flows almost due S., with a full and rapid current, until it reaches the Mediterranean. The Loire has much the longest course of any river in *F.* It rises to the S. of lat.  $45^{\circ}$ , flows in a N. direction above 200 m.; turns, near Orléans, to the W.; is joined by the Cher, Indre, and Vienne from the S., and, after receiving the Sarthe from the N., falls into the Atlantic below Nantes. The Garonne, a river of less length of course, but of greater volume of water, descends from the French side of the Pyrenees, flows N., and after receiving from these mountains a number of tributary streams, of which the chief is the Arriège, turns to the W. near Montauban (lat.  $44^{\circ}$ ), and falls into the Atlantic after being augmented by the waters of the Tarn, Aveyron, Lot, and finally the Dordogne, — all flowing from the W. face of the mountains of Auvergne. *F.* has very few lakes, either in the mountainous districts of the S., or in the great levels of the N. and W. It contains, however, a number of maritime inlets, forming inland bays, and communicating with the sea only by a channel of greater or less width. These occur partly in the S. W. coast, in Gascony; but more in the S. and S. E., in Languedoc and Provence. Their want of depth prevents them from serving as roadsteads for shipping, and they are useful chiefly for fishing, or for the manufacture of bay-salt. — *Forests.* The total extent of ground covered by wood is computed at 32,250 sq. m., about one sixth of the surface of the country. There are forests in almost every department. Lower Normandy contains several of considerable extent. There is a large one at Fontainebleau, only 45 m. from Paris, and a larger to the N. of the Loire, in the vicinity of Orléans. The department of Ardennes and the mountainous tract that forms the boundary of France on the side of Switzerland, abound in forests. The State possesses 991,703 hectares (3,833 sq. m.); 1,903,253 hectares (7,318 sq. m.) belong to the *communes*, or to public institutions, and are managed by the state; the rest are private property. They represent a total value of about three thousand millions of francs (\$30,000,000), the annual revenue of which exceeds \$7,000,000. — *Climate.* The climate of *F.* is generally temperate, but by no means uniform. The division into the north, west, south, and central regions, although it seems the most natural, does not satisfactorily correspond to the actual differences. A more convenient division is that of the following four regions or zones: the region in which the olive-tree is cultivated, which is limited by a line from Bagnères-de-Luchon (Haute-Garonne) to Die (Isère); the region of the maize, or Indian corn, from the mouth of the Gironde to Laon-L'Etape (Vosges); the region of the vine, from the mouth of the Loire to Metziers (Ardennes); and the northern region, which is characterized by the culture of the apple-tree. These limits are, however, far from being absolute: the Indian corn, for example, is successfully cultivated in Brittany, and vineyards are to be found much farther N. than the mouth of the river Loire. The N. and N. W. of *F.* bear a great resemblance, both in temperature and produce, to the S. of England, rain occurring frequently, and the country being consequently fit for pasture. In the interior the rains are less frequent, but, when they occur, are far more heavy, so that there is much less difference in the annual rainfall there as compared with the rest of the country than in the number of rainy days; but, on the

whole, the climate of the interior is the most pleasant in *F.*, that region being exempt equally from the oppressive heat of the S. and the frequent humidity of the N. The great current of wind which prevails in *F.* blows from W. to E. from the Atlantic, over the whole surface of the country, except the lower basin of the Rhone, where the *mistral* (a cold wind coming from the N. N. W.), the E. wind, blowing from the Alps, and the S. winds, do considerable damage both to the produce of the soil and to the health of the inhabitants. Pau, Cannes, Nice, &c., in the south, are much resorted to by invalids, and by foreign families for winter-quarters.

Fig 206. — WOODEN HOUSES OF THE MIDDLE AGES (LISIEUX)

*Communications.* Before referring to the state of agriculture, manufactures, and commerce in *F.*, it is important to have an idea of the means of communication by which the different productive districts are connected with one another. The minister of public works has the superintendence of all roads and ways, natural or artificial, by land or by water. A special department, called *Administration des Ponts et Chaussées*, assisted by a council with the minister as its president, is charged with the management of that important branch of public business: 569 engineers and inspectors, and 2,163 inferior officials, form the administrative staff. — *Roads* are either national, departmental, military, or *vicinal* (cross roads). National roads are kept up entirely at the expense of the public treasury. The departments have to provide for departmental roads and a portion of the military roads, the rest being charged on the state. As to cross-roads, or *chemins vicinaux*, they depend on the ministry of the interior, and are kept up by the *communes*, or, when of a higher importance, by the de-

partments. At the end of 1811, 229 roads were classified as imperial roads. They extended over a length of 46,500 kilomètres (28,894 m.). In 1815, after the territory of *F.* had been brought back to its ancient limits, the length was only 27,200 kilomètres (16,901 m.); in 1873 there were 223 national roads, giving a total of 37,394 kilomètres (23,180 m.), 2,627 kilomètres (1,632 m.) of which are still paved like a street. The average breadth of that class of road is 16 mètres (52 feet 6 inches), 6 mètres for causeway, 6 for the sidewalks, and 4 for the ditches and embankment. Although the great extension of railways has somewhat reduced the importance of high-roads, it has been calculated that the traffic has changed very little during the last twenty years. The departmental roads are not quite so wide as the national ones, their average breadth being 12 mètres (39 feet). In 1872 their length was 46,839 kilomètres (29,167 m.). Military roads were made in the *W.* of *F.* after the last insurrection of Vendée. They are 28 in number, distributed in the departments of Charente-Inférieure, Ile-et-Vilaine, Loire-Inférieure, Maine-et-Loire, Mayenne, Sarthe, Deux Sèvres, and Vendée, and extend to a length of about 1,600 kilomètres (932 m.). A sum of nearly 34 millions of francs is spent yearly for the purpose of making new roads or repairing old ones. The *chemins vicinaux*, or cross-roads establishing a communication between rural places not far distant from each other, are managed by a special branch of the department of the minister of the interior; about 3,000 *agents voyers* and 42,000 *cantoniers*, or workmen, are specially charged with the duty of keeping them in repair. In 1872 these roads, divided into three classes according to their importance, were 544,330 kilomètres (333,273 m.) in length, and covered a surface of about 370,000 hectares (915,000 acres). To the very considerable resources which the communes must apply to the extension and repair of their rural roads, the government used to add a yearly grant of 11,500,000 francs; but this sum has been reduced to 5,750,000 francs since 1873. The *Annales* of the administration of the *Ponts et Chaussées* mention 1,982 large bridges, of which 79 are cast-iron. The chief are the bridge over the Gironde at Bordeaux, which has 17 arches, is 501 mètres (1,643 feet) in length, and cost 6,850,000 francs; the bridge of Cubzac, over the river Dordogne; the turning bridge of Penfeld at Brest; the bridge St. Esprit, over the Rhone, with 18 arches on a length of 739 mètres (2,395 feet); those of Toulouse, Libourne, Tours, and Rouen; the new bridge (*Pont-Neuf*) and the bridge of Léna at Paris; and the bridge of La Guillotière at Lyons. — *Railroads.* The growth of the railroad system of *F.* dates from the year 1840, previous to which there were but few lines in *F.* For a time the plan was entertained of making all the railroads which were to be built state property; but in the end it was determined, and settled by law, that the work should be left to private companies, superintended, however, and, if necessary, assisted in their operations, by the state. Under this arrangement the whole of the railroads already made, and about to be constructed, were classed under two divisions, called *ancien réseau*, or Old network, and *nouveau réseau*, or New network; the former, as implied by the name, representing the first-built main arteries of traffic, and the latter the by-roads, laid down, in most instances, with a view to public utility rather than to profit. On this account, the lines coming under the designation of New network received the grant of a state guarantee of four francs per cent interest, with 65 centimes additional for a sinking-fund, on the expended capital. The following table shows the length of railroads built each year in *F.* since 1853, and the total open for traffic on the first of January of each year:—

Years	Lines opened during the year.	Total length open at the end of the year.	Years	Lines opened during the year.	Total length open at the end of the year.
	Km.	Km.		Km.	Km.
1853	316	3,862	1866	515	13,583
1854	190	4,052	1867	953	14,536
1855	589	4,641	1868	1,193	15,729
1856	886	5,527	1869	606	16,335
1857	664	6,191	1870	795	17,130
1858	1,262	7,453	1871	665	17,795
1859	1,222	8,675	1872	672	17,965
1860	393	9,068	1873	111	17,776
1861	365	9,433	1874	763	18,539
1862	672	10,105	1875	542	19,081
1863	982	11,087	1876	721	19,802
1864	944	12,031	1877	555	20,357
1865	1,037	13,068	1878	680	21,037

It will be seen that from January 1, 1871, to January 1, 1872, the length of railroads opened for traffic declined from 17,750 to 17,965 kilomètres, notwithstanding that 665 kilomètres of lines were opened in the year 1871. The deficiency was caused by the loss of Alsace-Lorraine, which necessitated the sale of 759 kilomètres of railway, belonging to the Eastern Company,

to the government of imperial Germany. The chief lines, which are worked by powerful companies under the superintendence of the state are: (1) the *Chemins de fer du Nord*, which run between Paris and Soissons, Boulogne, Calais, Rouen, Amiens, etc., traverse the coal-districts of Picardy, and reach the Belgian territory at Quévrain and at Tournay; (2) the *Chemins de fer de l'Est*, from Paris to Strasburg, Mulhouse, and Basel in Switzerland, through Alsace, with branch lines to Sedan, Metz, Luxembourg, Rheims, Sarreguemines, etc., joining Belgian and Prussian railways at several points of the frontier; (3) the *Chemins de fer de l'Ouest*, which traverse Normandy in every direction, and connect Paris with the towns of Brittany; (4) the *Chemins de fer d'Orléans*, which go to Nantes, Bordeaux, Limoges, Bourges, and Toulouse; (5) the *Chemins de fer de Paris à Lyon et à la Méditerranée*, which connect the valley of the Seine with that of the Rhone, and have branch lines to St. Etienne, Clermont-Ferrand, Grenoble, Toulon, Cette, etc., establishing regular and direct communication between France and Switzerland,—the railways of Savoy being also worked by the same company. Paris is the starting-point and the administrative centre of all these lines. Another great line worked by the *Compagnie du Midi* starts from Bordeaux, which it connects with Cete and Bayonne, with branches between Bayonne, Toulouse, and Poix, Agen and Tarbes, Toulouse and Auch, Montpellier and Millau, etc. Through this line Spain is brought into communication with France. The capital required for the making of these railways has been calculated at not less than 10,000,000,000 francs,—which gives, for a total length of 21,987 kilomètres (13,662 m.), an average of 297,000 francs per kilomètre, or \$59,400. The yearly returns of the companies show an average income of \$168,000,000. By a law passed in 1873 there will be added 16,000 kilomètres (10,000 m.) of railroads before the end of the year 1888. To provide for the cost of the new network of railroads, the Chambers granted a credit of 3,000,000,000 francs, or \$600,000,000.—*Navigable Rivers and Canals.* All navigable rivers are state property. A table is subjoined of the navigable rivers arranged by basins, with the length of their navigable course, and also of the canals and the small rivers which have been converted into canals. Owing to the cheap rate of transport by water, canal traffic has been but little injured by the extension of railways, this inexpensive way of conveyance being used for heavy goods whenever practicable. In 1875, 1,721,070,943 kilométric tons (about 1,748,500,000 tons avoirdupois) were carried by river and canal navigation, besides 176,551,434 cubic mètres (230,933,000 cubic yards) of wood or *bois flotté*. The duties levied on these goods amounted to more than 4,177,940 francs.

**Agriculture.** In the general description of the country, some information has been given as to the nature of the soil and its various kinds of produce, which must be supplemented here. The extent of agricultural improvement in *F.* since the first Revolution has certainly been less than in England and Scotland, and it has been repeatedly said that this inferiority had its chief cause in the insignificant size of the occupancies, a feature of French agriculture which Arthur Young observed in his time, but which has been much increased by the law obliging a father to make an almost equal division of his property amongst his children. It would be perhaps nearer the truth to say that generally the more fertile a country is the less care the inhabitants take to cultivate it; if we add to this the influence of the climate, which makes country people more frugal, and at the same time more indolent, we shall be able to account for the difference in the state of agriculture as between the N. and the S. provinces of *F.* It does not appear, however, that land thus divided produces less in proportion than large estates, and, notwithstanding the great progress that *F.* has still to make, it is in an agricultural point of view as rich as any other country. The following table, taken from official documents, exhibits the physical and agricultural division of the French territory. —

	Hectares.	Sq. Miles
Arable land .....	25,500,675	98,469
Forests, woods, and parks .....	8,400,349	33,078

Olive, almond, and mulberry plantations .....	19,262	421
Miscellaneous .....	775,743	2,955

The *Statistique Oſſicelle* gives a statement of the average value of land per hectare, and the average rent paid for it, distinguishing in each case three classes of land thus: (1) Land under tillage; value, 3,096, 2,175, 1,375 francs; rent, 96, 62, 45 francs; (2) meadows; value, 4,151, 3,958, 2,022 francs; rent, 152, 104, 72 francs; (3) vineyards; value, 3,561, 2,638, 1,783 francs; rent, 139, 98, 68 francs. — The value of wood varies from 2,877 to 1,435 francs for the forests, and from 1,981 to 529 francs for coppices. — The cultivation of grain has always been the chief business of French agriculturists. In 1876 about 15,000,000 hectares were under this crop, distributed thus: —

	Hectares.	Average Crop per Hectare	Total Produce.
		Hectolitres.	Hectolitres.
Wheat .....	6,937,410	12.94	83,861,193
Meadow .....	7,631,138	12.70	6,287,331
Rye .....	1,912,031	10.83	20,779,367
Barley .....	1,118,071	16.75	18,732,827
Oats .....	3,182,459	21.31	67,891,966
Buckwheat .....	677,627	11.45	9,722,257
Malze .....	696,363	14.72	8,918,332
Millet .....	49,984	12.24	612,031

Wheat sells at prices varying from 20 to 26 francs a hectolitre (81 lb. to 215 lb. a quarter), and costs the agriculturist about 17 francs 50 centimes (\$10.15 a quarter). The quantity which is produced in France, large as it is, does not meet the wants of the population, and several millions of hectolitres are every year imported from Russia, Roumania, Spain, Italy, Egypt, and the U. States. — The cultivation of meadow and rye is on the decline; wherever the progress of agricultural science has succeeded in making a poor soil more rich and fertile, wheat takes their place, as being better and more profitable. — The area allotted to barley has been much the same for a long period, and is likely to remain so. The same may be said of maize, which is especially cultivated in the east and south-west, and of buckwheat, which in Auvergne and Brittany forms no small part of the food of the inhabitants. Oats are extensively cultivated, and yield a good return; this crop was on the increase from 1815 to 1862, but has since been almost stationary. — Potatoes form a very important article, occupying in 1876, 1,176,496 hectares (2,977,220 acres), and yielding 129,410,929 hectolitres (33,274,554 bushels). — The other crops are tabulated here, with the results they yielded for 1876: —

	Hectares	Average Crop	Total.
		Hectolitres.	Hectolitres.
Pease, beans, etc. ....	622,681	13.74	4,434,197
Chestnuts .....	482,247	13.68	6,567,381

Miscellaneous .....	10,500	20	319,898

\* The quintal metrique is 3½ lbs. less than two cwt.

**Meadows,** both natural and artificial, are very numerous in France, and give a higher return than any other kind of land. — The *vergades* cover 4.27 per cent of the surface of France, and are one of the chief sources of its agricultural wealth. They are to be found, more or less, in every district, except in two northern departments, viz. Calvados, Gŕetes-du-Nord, Nord, Finistère, Manche, Nord, Orne, Pas-de-Calais, Seine-Inférieure, and Somme. The departments in which the vine is most extensively cultivated are, — Haut, 162,152 hectares; Charente-Inférieure (157,763), Gironde (126,220), Charente (100,008), Gers (91,790), Gard (94,240), Dordogne (87,252), Aude (81,809), Var (79,040), Lot-et-Garonne (9,166). The vintage of 1876 gave a total of 41,946,748 hectolitres (321,033,017 gallons). It is very difficult to say to what extent the ravages of the *Phylloxera* have affected and may still further affect the production of wine either in quality or quantity. It has unquestionably had the effect of raising the price of the finer wines 25 to 35 per cent in 1879. (See BUDGET OF WINES, CHAMPAGNE, CRUKET WINES, etc.) — *Livestock.* The last census gave 2,822,851 as the total number of horses, comprising 400,154 colts, 331,654 stallions of 4 years and upwards, 872,911 geldings, and 1,257,832 mares. The number of mules was 269,129 and of asses 450,625. There were 10,023,716 head of cattle and 24,707,496 sheep. The goats, particularly numerous in Corsica and some mountainous parts, were 1,591,725. The addition of 2,500,000 beehives, of a total value of about 32,800,000 francs, 58,300,000 poultry of all kinds, and 2,000,000 dogs completes the enumeration in its principal divisions of the live stock of agricultural *F.*

**Manufactures.** One of the foremost branches of manufacture in France is that which has for its object the working up to textile materials. The gross amount of its produce is not less than 3,500,000,000 francs (\$700,000,000 a year), and the latest statistics (published in 1873) return it as employing 3,848,181 men, 396,898 women, 69,948 children, 2,777 steam-engines, and about 9,500,000 spindles. These figures relate to the period between 1861 and 1865, and are certainly very much less than if the enumeration had been taken more recently. — The flax gathered in 1873 weighed 54,874,740 kilogrammes (1,081,270 cwt.), and represented a minimum value of 84 millions of francs; to which must be added 10,188,721 kilogrammes (207,795 cwt.) of hemp, at an average price of one franc a kilogramme. About 800,000 spindles are kept busy with this material. In this branch of trade the department of Nord ranks first. It manufactures more than one third of the total amount of linen produced. Seine, Sarthe, Marne-et-Loire, Seine-Inférieure, Calvados, Ille-et-Vilaine, Lot-et-Garonne, Indre-et-Loire, and Seine-et-Oise are, next to the department of Nord, the chief seats of this industry. — The cotton manufacture has its centre in Normandy. More than a third of the total produce of the French cotton-loom comes from the department of Seine-Inférieure, Nord, Vosges, Calvados, Aisne, Aube, Orne, Meuse, and

Eure have also a large share in the production of cotton yarn and cotton cloth. The department of Rhône is famous for its cotton mullins, the value of which is not less than 28 millions of francs. Meurthe produces a special kind of trimming, valued at about 3 millions of francs a year. French cotton goods cannot cope in cheapness with the English, but they are of fine quality, and on this account command a sale in the markets. In the absence of authentic documents, we may safely estimate the produce of cotton manufacture for 1878 at 500 millions of francs, and the plant engaged in the trade at 6 millions of spindles and 260 millions of looms of various kinds. The loss of Alsace has been a heavy blow to the cotton-trade of France. — In the *woollen* factories 3,200,000 spindles are employed, giving work to more than 172,000 people. Wool fabrics amount in value to 1,200,000,000 francs (\$240,000,000), figures which present a striking contrast to the valuation of Count Chaptal in 1812, which was not above 250 millions of francs. Large manufacturing houses are to be found especially in the departments of Ardennes (Sedan), Nord (Lille, Cambrai, etc.), Marne, Eure (Louviers), Hérault; while Rhône is noted for shawls, Bouches-du-Rhône for washing and combing wool, Calvados for wool yarns, Aisne for both yarns and tissues, Aube for drapery, etc. The special manufacture of Paris is that of shawls, damasks for furniture, merinos, and lighter fabrics, as gauzes, muslins, bûrges, etc. — The rearing of *silk-worms* and the production of *silk* can be traced far back in the industrial history of France. The first Avignon pope, Clement V., is said to have introduced the first silk-worms and the first mulberry-trees (1305). This branch of industry soon assumed a national character, and all kings who, like Louis XI. and Henry IV., cared for the progress of commerce and manufactures, gave it encouragement and privileges. In 1780 France produced 6,500,000 kilogrammes of cocoons (14,519,194 lbs.), having a value of 15,500,000 francs. In 1876 *F.* produced 9,871,116 kilogrammes of cocoons, which gave 635,800 kilogrammes (12,547 cwt.) of raw silk. Twenty-one departments are engaged in the rearing of silk-worms, — those which yield the largest produce being Gard, Drôme, Ardèche, Vaucluse, Bouches-du-Rhône, Var, Isère, Hérault, Basses-Alpes, etc. After having undergone the various operations which transform the cocoon into regular yarn, the silk goes to the weaver. Nine tenths of the silk is woven at Lyons, by 120,000 looms, belonging to 400 firms, who every year produce silk goods to a value of about 450 millions of francs. — The manu. of *lace* gives employment to 240,000 women at Alençon, Baillieux (Vallenciennes), Lille, Chantilly, Caen and Bayeux, Mirécourt, Le Puy, and Paris; and there are 150,000 *embroiderers* in the departments of the N and E. The two industries contribute to the public wealth about 90 millions of francs every year. — Paris, Grenoble, Lunéville, Vendôme, Blois, Béziers, Ammonay, and Nîmes are the chief seats of the manu. of *gloves*, which represents a sum of about 70 millions of francs. — *Beet sugar* is extensively made in the North of France. The manu. of this sugar in a raw state was thus distributed for the year 1876: —

	Kilo-grammes.	Cwt.
Aisne .....	92,721,965	1,827,034
Nord .....	111,111,773	2,189,454
Oise .....	41,397,892	815,131
Pas-de-Calais .....	60,102,110	1,134,278
Somme .....	67,747,541	1,334,927
Other departments .....	75,517,002	1,493,931

These quantities are produced by about 510 manufactories. Ninety establishments are especially engaged in refining the first produce extracted from beet-root, or from the sugar cane; about 180,000 tons of raw sugar are received annually from the colonies, French and foreign, by these refining establishments, which employ 3,400 workers. The yearly value of the manu. amounts to 140 millions of francs. — *Liquors*. Wine, brandy, and the juice of the beet-root are the substances from which the largest quantity of the alcohol produced in France is extracted. About 3,500 firms are engaged in distillation; the produce for the year 1876 was divided thus: —

	Hec-tolitres.	Gallons.
Alcohol distilled from wine .....	415,967	9,155,295
" " corn and potatoes .....	97,437	2,145,217
" " beet-root .....	315,021	6,933,572
" " treacle .....	681,731	15,004,739
" " other substances .....	48,017	1,056,888
Total .....	1,558,209	34,295,661

Normandy and Brittany are the chief centres for the production of *cider*. In 1876 about 7,035,669 hectolitres (154,845,539 gallons) were manufactured. There are about 3,200 brewers, who send out not less than 7,400,000 hectolitres of beer (162,

871,543 gallons), worth about 200 millions of francs; but, as hops are but little cultivated in *F.*, 3 millions of francs are spent yearly in importing them. The largest manufactories of *v. negar* are in the departments of Loiret and Loire-Inférieure; it is made almost exclusively from wine, but malt and some other substances are now beginning to be used. The total value is about 3 millions of francs. — The principal *soap* manufactories are at Marseilles, its production being 800,000 quintals (1,576,354 cwt.); Nantes and Paris hold the second rank. It has been calculated that *F.* produces annually 2 millions of quintals (3,940,886 cwt.) of soap. *Candles* are chiefly made at Paris. This branch of manufacture has a total value of 300 millions of francs, whilst the production of soap amounts to 450 millions. French *perfumery* is appreciated through the world, and gives a yearly return of more than 50 millions of francs. — *Pottery and Glass*. The departments of Vienne, Seine, Sarthe, and Puy-de-Dôme are the centres of the fabrication of earthenware and bricks; in Haute-Vienne, Var, and Gironde the special manufacture is china. The annual produce of this industry is valued at 150 millions of francs. A great manufactory kept up by the state at Sévres forms a school in which artistic workmen are trained, so that the art is maintained in a high degree of perfection. Crystal wares are made in eight works established in the departments of the Meurthe-et-Moselle, Seine, and Orne, among which special mention must be made of Baccarat, which is to this branch of industry what Sévres is to the ceramic. Looking glasses are a very important article of manu. in *F.* that country possessing no fewer than 6 out of the 15 or 16 establishments in Europe. The principal manufactory is at St. Gobain (Aisne), and the value of the produce of the whole is above 14 millions of francs. Glass of a more common kind is made in about 250 establishments, and is valued at 80 millions of francs. The departments of Nord, Haute-Saône, Haute-Loire, Allier, Seine-Inférieure, Seine, Aveyron, and Loire are famed for common window and plate glass; bottles are chiefly manu. in the department of Nord, and in the basins of the Loire and Rhône. — The most important paper-mills are situated in Charente, Pas-de-Calais, Seine-et-Oise, Isère, Vosges, Seine-Inférieure, Seine, Eure, and Seine-et-Marne. Paris is celebrated for its *paper-hangings* and stained paper. The produce of this manufacture is valued at 75 millions of francs. — *Coal and Iron*. The principal mines which *F.* possesses are coal and iron mines. Coal-pits are almost exclusively confined to the east, southeast, and north of the country. The richest departments are Nord (239 square miles), Pas-de-Calais (201), Gard (187), Saône-et-Loire (165), Hérault (113), Loire (110), and Bouches-du-Rhône (107). The whole area is about 2,200 square miles, and comprises 23 separate concessions, which, however, are not all being worked. The yield of coal-mines in 1876 was 170,477,613 quintals (16,795,824 tons), the following being the most productive districts. —

Names of the Basins.	Departments.	Quintals.

Maurienne-Tarentaise, Briançon .....	Hautes-Alpes, Savoie .....	299,690

France is very rich in iron-mines; but as these are generally far from the districts which produce coal, the working expenses are considerably increased, and sometimes to such an extent that the metal extracted cannot repay the outlay required for its extraction, and the mines have to be abandoned. The production of iron, however, is on the increase, and reaches 7½ millions of quintals (738,915 tons), which represent about 14,500,000 quintals (1,428,571 tons) of pig-iron. — *Gold and Silver Work*. Paris is the chief centre of the manu. of arti-

the objects in gold and silver. In 1876 the workmen were 19,275 in number, distributed among 4,072 establishments, and the business was transacted to the value of not far from 200 millions of francs. Lyons holds the second place, and then Bordeaux, Marseilles, Nîmes, Besançon, Clermont-Ferrand, and Toulouse. — The manufacture of *watchcases and clocks* yields a revenue of 30 millions of francs. Large iron clocks are made at Morez (Jura); time-pieces are constructed in part at St. Nicolas d'Admont (Seine-Inférieure) and at Montbéliard, and finished at Paris; watches are begun at Montbéliard and Cluses (Haute-Savoie), and finished at Paris and Besançon. This last town is the central place of the trade, and represents 90 per cent of the total manufacture. 15,000 persons, men, women, and children, are employed in this trade, and in 1876 they turned out 146,381 gold and 274,811 silver watches.

The chief commercial business of Paris is necessarily inland; but it is the centre of exchange transactions for *F.*, foreign as well as inland, as London is for England. Havre de Grace is the channel for the maritime intercourse of the capital, the outlet for its exports, and the medium through which it receives colonial produce, raw materials, and foreign manufactures.

The *inland trade* is greatly more important than the foreign trade. It is impossible to give a strict and correct valuation of the inland traffic, but judging of the whole from the few accessible details, we may, without exaggeration, estimate its amount at about 40 milliards of francs (\$8,000,000,000).

The *coasting trade* has always been of great importance in *F.* In 1876 the total weight of goods transported by coasters was 2,022,559 tons, an increase of nearly 7,000 tons on the preceding year. These goods were of various kinds, — building materials (258,174 tons), wines (225,595 tons), salt (213,185 tons), wood (207,211 tons), corn and flour (193,451 tons), coals (125,243 tons), being the chief articles in the general traffic. 62,395 vessels, the tonnage of which amounted to 3,297,933 tons, were engaged in this trade, while in 1874 there were only 57,883, of 2,952,414 tons. The harbors most frequented by coasters are Marseilles, Le Havre, Bordeaux, Dunkirk, Rouen, Calais, Dieppe, Nantes, St. Nazaire, and Boulogne.

*Fisheries.* The annual produce of river and pond fishing

in the interior of *F.* may be valued at about 10 millions of francs. Coast-fishing was carried on in 1871 by 8,365 boats, manned by 38,150 men, with a tonnage of 68,517 tons, giving a return of 51,000,200 francs. In 1876 the increase was considerable, the number of the boats being 20,159, the tonnage 101,852 tons, the crews 65,651 hands, and the revenue 61,780,100 francs. The same year 178 vessels, with a tonnage of 31,235 tons, and manned by 7,890 men, sailed from French ports to fish for cod on the coasts of Newfoundland. The average value of the Newfoundland fisheries is estimated at about 17 millions of francs. The rearing of oysters has of late made very great progress in *F.* Large beds are established on almost every suitable point of the coast, as at Calcarre, Auray, Marennes, Oleron, and Arcachon. The last-named place is the most important of all the beds being not fewer than 2,427, which gave for 1876 a return of 3,941,369 francs, represented by 196,885,450 oysters.

*Foreign Trade.* Although the principles of free trade are now better understood in *F.* than they were formerly, and are generally considered by French economists and statesmen as most conducive to the interests of a nation, their application is still far from complete, owing to the enormous charges brought upon the country by the late war, but chiefly to the personal influence of M. Thiers, the first president of the republic, who was a determined upholder of protection. This is not the place to enter on any discussion of the merits of the two opposite doctrines; but the fact does not admit of question that, notwithstanding the tax on raw materials and other duties which hamper the commercial intercourse of *F.* with other nations, her foreign trade has been constantly increasing. The foreign trade of *F.* is divided into *commerce générale*, which comprises the entirety of imports and exports, including goods in transit and precious metals, and *commerce spécial*, which embraces the imports consumed within, and the exports produced within the country. The general commerce of the year 1878 was valued in imports at 4,350,000,000 francs (\$870,000,000), and the exports at 4,820,000,000, (\$964,000,000). The following tables give the value, in francs, of the special commerce of *F.* with foreign countries in the years 1874, 1875, and 1876:—

COUNTRIES.	IMPORTS.			EXPORTS.		
	1874.	1875.	1876.	1874.	1875.	1876.

The following statement shows the value of the four groups of imports and of the three groups of exports, according to the classification adopted by the French Douane, or Custom House, in each of the years 1876 and 1877:—

IMPORTS.	1876.	1877.
	Francs.	Francs.
Articles of food .....	972,960,000	957,668,000
Raw materials .....	2,367,833,000	2,154,067,000
Manufactures .....	403,405,000	450,456,000
Other articles .....	184,165,000	194,177,000
Total .....	3,988,363,000 \$797,672,600	3,756,368,000 \$751,273,600
EXPORTS.		
Manufactures .....	1,894,268,000	1,846,092,000
Articles of food and raw materials.	1,487,716,000	1,448,736,000
Other articles.....	193,610,000	189,494,000
Total .....	3,575,594,000 \$755,118,800	3,484,323,000 \$696,865,000

The imports of coin and bullion—not included here were of the value of \$12,215,000 francs (\$132,443,000), and the exports of the value of 157,995,000 francs (\$31,599,000).—The foreign trade is for a great part carried on by sea. *F.*, however, has a very limited number of trading vessels; and foreign ships, chiefly English, convey about two-thirds of her goods, both imports and exports. The number of laden vessels entered and cleared in 1876 was as follows:—

Nationality.	Total.		Steamers.	
	Vessels.	Tons.	Vessels.	Tons.
French .....	18,170	5,072,000	6,218	3,495,000
Foreign .....	35,952	9,002,000	16,953	6,276,000
Total .....	54,122	14,134,000	23,171	9,771,000

The commercial navy, in 1877, was as follows:—

Class of Vessels.	Vessels.	Tons.	Crews.
Sailing vessels .....	14,851	792,836	84,801
Steamers .....	546	218,449	10,237
For port service.....	498	9,631	2,090
Fishing vessels .....	9,590	133,521	53,077
Coasting vessels .....	2,604	115,925	10,336
Long-voyage vessels .....	2,328	728,530	29,218
Vessels out of use or probably lost	387	22,678	409
Total 1877 .....	15,407	1,011,285	95,138
" 1876 .....	15,441	1,028,228	95,164
" 1875 .....	15,524	1,037,272	98,022

*Commerce with the U. States.* A "Convention of Navigation and Commerce," signed by the plenipotentiaries of the two powers on the 24th of June, 1822, and ratified and declared in operation by the U. States on the 12th of February, 1823, provides that articles, the growth, produce, or manufacture of the U. States, when exported to *F.* in vessels of the U. States, shall pay an additional duty not exceeding 20 francs (\$3.75) per ton of merchandise, over and above the duties paid on the like articles exported to *F.* in French vessels; that articles, the growth, produce, or manufacture of *F.*, imported into the U. States in French vessels, shall pay an additional duty not exceeding \$3.75 per ton of merchandise, over and above the duties paid on like articles imported in vessels of the U. States; that no discriminating duties shall be levied upon the productions of *F.* imported in French bottoms into our ports for re-exportation; that a like advantage shall be given, and is given, to the U. States; that the following quantities shall be considered a ton for the articles specified, viz.: Four 61 gallon hogheads, or 244 gallons of 231 cubic inches of wine, American measure; 244 gallons of brandies and all other liquors; 50 cubic feet of silk, American measure, in the U. States; and 42 cubic feet, French measure, in *F.*; 804 pounds avoirdupois of cotton; 1,600 pounds avoirdupois of tobacco; 2,240 pounds avoirdupois of pot and pearl-ashes; 1,600 pounds avoirdupois of rice; and for all weighable articles not specified, 2,240 pounds avoirdupois; that the duties of tonnage, light-money, pilotage, port charges, brokerage, and all other duties on foreign shipping, over and above those paid by the national shipping in the two countries, other than those above specified, shall not exceed, in *F.*, for vessels of the U. States, 5 francs (94 cents) per ton of the vessel's American register, nor for vessels of *F.* in the U. States 94 cents per ton of the vessel's French passport; that the convention shall remain in force two years from the 1st of October, 1822, and after that time until the conclusion of a definite treaty, or until one of the parties shall have declared its intention to renounce it, which declaration shall precede the renunciation six months. Several conventions of limited duration have since slightly modified the convention of 1822, which, however, has not been annulled. The trade between the U. States and *F.* is therefore still substantially regulated by the convention of 1822, and guarded by the powers and privileges secured to the consuls of each nation by the consular convention of February 28, 1853. In 1878 the Chamber of Commerce of New York sent a committee to represent it at a Congress held in Paris to consider the provisions of a treaty of commerce between *F.* and the U. States. Later, M. Leon Chocteau, delegate of the French National Board of Trade, who had been active in the presentation of the subject before the commercial institutions of the U. States, revisited America with the bulletins issued by the French Association to promote a treaty. M. Chocteau presented his views at the Chamber of Commerce of New York at its meeting of March, 1879, whereupon a Special Committee was appointed to inquire into and report on the subject. No further action of any definite shape was taken on the subject, upon which there was and still exists considerable difference of opinion in this country.

The subjoined tabular statement shows the declared value of the total exports sent from *F.* to the U. States, and of the total imports of American produce and manufactures into *F.*, in each of the 20 years from 1859 to 1878:—

Year ended June 30.	Imports from United States to France.		Total Exports.	Exports from France to United States.	Total Imports and Exports.
	Domestic.	Foreign.			
1859 .....	\$43,031,473	\$1,268,145	\$44,299,618	\$41,301,147	\$85,600,765

" (manu- factures of).....	22,255	Watches.....	41,354
Hemp (manufac. of).....	55,838	Wearing apparel.....	28,731
Hides and skins.....	232,120	Whalebone.....	91,019
Iron (machinery).....	73,745	Wool, and manu- factures of.....	657,122
Resin and turpen- tine.....	45,550	All other articles, each under \$50, (94)	685,622
Mineral oil, crude.....	1,938,065		\$56,101,900
" refined.....	301,414		

In 1878, 174 American vessels (tonnage 119,212) entered, and 123 (tonnage 90,234) cleared the French ports.

**Finances.** The total income of the public treasury in F., including the revenues of the departments and communes, is above 3,000,000,000 francs (950,000,000), which is more than any other nation has to pay for the expenses of its government; and yet this enormous sum has not been sufficient to meet the wants of the state, for repeated loans have constantly increased the public debt. Not taking into account the petty payments of all sorts that government has always to make, the public debt is divided into funded (*dette consolidée*) and floating debt (*dette flottante*). The funded debt is not subject to reimbursement, but only to the payment of a certain interest fixed by law. This debt, which was arranged by the law of the 9th of Vendémiaire year VI (27th September, 1795), to liquidate the old debts of the monarchy, then amounted to 40,216,000 francs of interest to be paid yearly to the creditors. From 1800 to 1814 it increased by 22,091,635 francs; and the Government of the Restoration added 101,290,403 francs, making a total of 164,598,140 francs in interest. Louis Philippe carried it to 178,345,337 francs, and at the time of the *coup d'état*, it amounted to 220,768,863 francs. The second empire, during a period of eighteen years, created 168,187,963 francs of consols, thus charging F. with an annual payment of 308,956,526 francs. As an unavoidable consequence of the Prussian War, the funded debt has been still further increased, so that the interest was 748,503,642 francs in 1874, and 747,571,000 francs in 1877, which gives an average of about 21 francs per head of the population.—The floating debt, which the government contracts either by receiving private deposits and using

them for its needs or by issuing bills of exchange called *bons du trésor*, amounted in 1872 to 761,000,000 francs. This part of the public debt, including some other items under the name of *capitaux remboursables à divers titres*, appears in the budget of 1877 for the much lower figure of 300,226,686 francs (\$60,045,357).

The principal sources of revenue and branches of expenditure in the budget estimates for each of the two years 1877 and 1878 were as follows:—

REVENUE.	1877.	1878.
	Francs	Francs
Direct taxes.....	388,179,000	362,114,000
Special taxes assimilated to direct

	\$533,459,350	\$569,297,019

All the departments of F., as well as many of the great cities, have their own budgets and debts, which latter were largely increased by the war. The budget estimates of the city of Paris for each of the years 1877 and 1878 were as follows:—

REVENUE.	1877.	1878.
	Francs	Francs
Ordinary receipts.....	213,848,277	218,605,436
Extraordinary receipts.....	57,495,934	33,417,840
Total revenue.....	271,345,210	254,023,335
	\$54,269,042	\$50,812,067
EXPENDITURE.		
Ordinary expenditure.....	211,848,277	217,607,285
Extraordinary expenditure.....	59,496,933	36,456,060
Total expenditure.....	271,345,210	254,063,335
	\$54,269,042	\$50,812,067

The principal source of revenue in the budget of the city of Paris is from tolls upon articles of general consumption, called *droits d'octroi*, which were calculated to produce 122,203,250 francs in the year 1878. The principal branch of expenditure is for interest and sinking fund of the municipal debt, set down at 106,577,211 francs in the budget for 1878. The nominal capital of the debt of the city of Paris at the end of September, 1878, amounted to 1,970,000,000 francs, or \$394,000,000. To this was added a loan of 325,000,000 francs, or \$65,000,000, issued in December, 1878, and raising the total debt to 2,295,000,000 francs, or \$459,000,000.

**Banks.** Besides the two banking companies especially founded with a view to assist agriculture, of which notice has been taken under that heading (*crédit foncier, crédit mobilier*), there are other establishments of credit which partake of the nature of public institutions, and must not be passed over in silence when speaking of French trade. The first of them is the *Banque de France*, founded in the year VII. (1799), and definitely organized by the law of April 26, 1806, which gives the management of the bank to a governor and two deputy-governors appointed by the chief of the state, and assisted by a council of fifteen *régents* and three *censeurs* elected by the shareholders. The capital of the bank of *F.* is 182,500,000 francs. Besides issuing bank-notes, which circulate as freely as gold, the bank has the power to discount bills and letters of exchange at three months, when endorsed by three signatures; to collect bills payable given to it by private persons or commercial houses for that purpose; to receive deposits and open current accounts; and to keep in trust the coupons, deeds, silver and gold bars, bullion, and jewels which may be entrusted to it, at the rate of one per cent per annum. The Bank of *F.* has now a branch in each department. In

Fig. 207. — CHÂTEAU DE CHENONCEAUX.

the following towns, Bourges, Cahors, Tarbes, Aurillac, Mende, Tulle, Digne, Belfort, Foix, Gap, Mont-de-Marsan, La Rochesur-Yon, and Meaux, these branches are not yet open; but the law has been passed, and their being opened is only a question of time. This establishment is the great instrument of credit in the country. It has more than once supported the government by loans in difficult circumstances. The government, which holds a great number of its shares, is therefore interested in its preservation, and, when money is unusually scarce, gives to its notes the value and privileges of coin, by decreeing what is called the *cours forcé*. This measure was resorted to during the late war, and confidence in the bank remained unshaken. During the year 1876 the quotation of the shares of the Bank of *F.* fluctuated between 3,875 and 3,470 francs. Of other banks the *Comptoir d'Escompte*, which dates from 1848 and was reorganized in 1854, the *Société générale de Crédit industriel et commercial*, founded in 1859 after the model of the London joint-stock banks, the *Société générale pour favoriser le développement du Commerce et de l'Industrie en France*, established in 1864, whose special feature is to endeavor to make use of checks popular in *F.* and the *Caisses des Dépôts et Comptes-courants*, are also worth mentioning. Among the local banks, the *Crédit Lyonnais*, the *Banque Parisienne*, the Colonial Banks, and the Bank of Algeria may be named as the most important.

**Coinage.** The coining of money is carried on by private contractors under the strict superintendence of the state.

There are now in *F.* six *hôtels des monnaies* (mints), in Marseilles, Bordeaux, Lille, Lyons, Paris, and Rouen respectively. Paris is the chief centre, and the other mints hardly now issue anything except copper coins. From 1795 till the 1st of January, 1874, the quantity of gold and silver moneys coined in *F.* was as stated below:—

Gold.			
Coins of 100 francs.....			Francs.
"	50	"	44,346,400
"	40	"	46,568,700
"	20	"	204,432,290
"	10	"	6,273,174,390
"	5	"	965,051,690
			210,947,190
			7,744,520,700
			or, \$1,548,904,140

Silver.			
	1795-1871.	1872.	1873.
Coins of 5 francs.....			
	Francs	Francs.	Francs.
"	4,685,641,250	389,190	154,649,045
"	70,512,344	7,547,588	1,056,152
"	86,998,118	15,963,333	19,101

"	2,504,728		
4,886,137,296			
26,838,339			
156,270,160			
Total, 5,069,245,825 francs,			
or, \$1,013,549,165.			

This amount (with 307,232,889 francs value received) is apportioned thus among the different governments which have ruled *F.* during the period specified:—

	Gold.	Silver.	Total.
	Francs.	Francs.	Francs.
First Republic.....		106,237,255	106,237,255
Bonaparte and Napoleon I....	528,024,440	887,830,055	1,415,854,495
Louis XVIII. ....	389,333,060	614,850,110	1,004,183,170
Charles X. ....	52,918,920	632,611,320	685,430,240
Louis Philippe ..	215,912,800	1,756,398,333	1,972,311,133
Second Republic.	427,282,860	459,248,232	886,531,142
Louis Bonaparte and Napoleon III. ....	6,151,951,600	626,294,792	6,778,256,392
Third Republic..	50,169,880	221,605,707	271,675,587
Total..... {	7,815,603,560	5,375,395,854	13,120,999,414
	\$1,563,122,712	\$1,061,079,170	\$2,624,194,883

Money is reckoned by the franc of 100 centimes, in value 10.3 cents.

**Weights and Measures.** The basis of all French measurements is the *mètre* (see METRIC SYSTEM). The measures in common use are here given, with their English equivalents:—

Gramme.....	=	15.434 grains troy, or about 30 grammes equal to an ounce.
Kilogramme.....	=	2.205 lbs. avoirdupois.
Quintal Métrique.....	=	220 "
Tonneau.....	=	2200 "
Litre, Liquid Measure.....	=	1.76 Imperial pints.
Hectolitre { Liquid Measure ..	=	22 " gallons.
{ Dry Measure ..	=	2.75 " bushels.
Mètre.....	=	3.28 feet or 39.37 inches.
Kilomètre.....	=	1093 yards, or nearly 5 furlongs, or $\frac{5}{8}$ mile.
Mètre Cube {	=	35.31 cubic feet.
Stere {	=	
Hectare.....	=	2.47 acres.
Kilomètre Carré.....	=	247 acres, or $2\frac{1}{2}$ K. C. to 1 sq mile.

**Colonies.** The colonies of *F.*, an account of which will be found under the particular headings, are,—in *Asia*, Pondichéry, Karikal, Mahé, Yanaon, Chandernagor, and Sumatra, and the French Cochinchina; in *Africa*, Senegal, with the island of Gorée, the island of Réunion or Bourbon, the islands of Sainte-Marie de Madagascar, Mayotte, and Nossi-Bé. In *America*, Martinique, Guadeloupe, St. Barthélemy, French Guiana, and the islands of St. Pierre and Miquelon; in *Oceania*, the Marquesas Islands, Tahiti, and New Caledonia. Among these settlements, Martinique, Guadeloupe, La Réunion, Cochinchina, and Guiana are, properly speaking, the only colonies, the rest being rather mercantile stations, except perhaps the French possessions near Madagascar and in the Pacific Ocean,

which have better prospects, and one of which, New Caledonia, now contains the principal penitentiary establishments maintained abroad by *F.* All these colonies submitted, till 1861, to what was called the colonial pact, which bound them to *F.* so closely and jealously that they could trade with no other nation than the mother-country. This state of affairs has been greatly changed, chiefly for Martinique, Guadeloupe, and La Reunion; and but for some privileges of navigation and some special taxes, trade with the colonies is almost as free as trade with *F.* itself. — In the above list is not included Algeria, which has a government and laws distinct from the other colonial possessions, being looked upon, partly from its proximity to *F.*, and partly from serving as camp and practice-field of a large portion of the standing army, as a more immediate annex of the mother-country.

**Seaports.** *F.* is but very inadequately provided with harbors, her long tract of coast washed by the Atlantic and the Bay of Biscay has scarcely three or four good seaports, and those on the southern shore of the Channel form a striking contrast to the spacious maritime inlets on the English side. To begin from the N. E., *Dunkirk* has a small harbor enlarged, however, by docks, and approached in the Dutch manner, by a canal leading from the sea. *Calais*, one of the best ports on the coast, is not to be compared with Dover. *Boulogne* has a roadstead, which has been of late greatly deepened and improved. The port of *Dieppe* is exposed, and of course unsuitable for winter. The best mercantile harbor in the N. of *F.*, *Le Havre*, at the mouth of the Seine, has large basins and docks, formed at a very great expense. *Cherbourg* is now a port and arsenal of great utility and importance to the navy. *St. Malo*, on the N. coast of Brittany, possesses a good and large harbor, with quays extending to a length of 2,955 metres (3,241 yards); its entrance is protected by fortified islets. Brittany also possesses *Brest*, the great maritime port of the Atlantic for the navy, and, in the S. W., *Lorient*. Proceeding further to the S., we find *Nantes*, with its two ports at the mouth of the Loire, *Paimbœuf* and *St. Nazaire*; *Les Sables d'Olonne*, now connected with Liverpool by a regular service of steamers; *Rochefort*, on the Charente, one of the great dockyards and naval stations; *La Rochelle*, a small but a cure harbor; and *Bordeaux*, where the Gironde is nearly equal in width to the Thames at London. From this there is no seaport worthy of mention until we reach *Bayonne*, a place of difficult access. On the Mediterranean, *F.* has the ports of *Cette*, *Marseille* (the most spacious and secure on the coast), *Nice*, and the great maritime port, arsenal, and dockyard of *Toulon*. — These ports are below separately given in their alphabetical order, and more or less briefly, according to their relative commercial importance.

**Bayonne** is a strongly fortified place in the department of Basses Pyrénées, at the confluence of the Nere with the Adour, 58 m. W. N. W. of Pau, in lat. 43° 29' 23" N., lon. 1° 28' 33" W. It is a fine and rich city, and a first-class fortress. The harbor is large and commodious; but there is a dangerous bar at its mouth. *B.* has extensive yards for the building of ships of war and merchant-vessels. Its commerce is chiefly with Spain; it has no direct trade with America. The hams of *B.* have long enjoyed a high celebrity. Pop. 22,357.

**Bordeaux** is one of the finest and wealthiest commercial cities of *F.*, formerly the capital of Guienne and Bordelais, and now the capital of the department of Gironde. It is situated 370 m. S. E. of Paris, in lat. 44° 54' N., lon. 0° 25' W., on the left bank of the Garonne, about 60 m. from its mouth, and in the middle of an extensive plain, which comprises the district of Medoc, well known for its red wines. Opposite the city the river makes a semicircular curve, and winds out into an extensive basin, which serves as a harbor, and is lined with quays on both sides for a distance of 3 m. This port is capable of accommodating upwards of 1,000 vessels, and such as do not exceed 800 tons can come up to the town. Ships of the greatest ordinary tonnage have depth enough as far as *Pandillac*, about 35 m. from the mouth of the river. The trade of *B.* is very extensive, particularly in wines, and has undergone a remarkable development since the introduction of railroads and steamships. For a long time *B.* was greatly indebted to the Languec canal, but this means of communication is now of minor importance. The total value of the export and import trade is annually about \$75,000,000, about a third belonging to Great Britain. In 1878 the value of *B.* wines exported from *F.* was upwards of \$28,000,000, and the brandy and liquors from *B.* itself annually produce about \$5,000,000. The other articles exported comprise corn, fruits, sugar, wool, tannin, eggs, madder, tarlar, gums, indigo, and native manufactures. Ship-building is a leading industry, the number of firms in that department being about twenty in 1878. In the same year 231 vessels belonged to the port, with a total tonnage of upwards of 92,000 tons. Pop. 93,062.

**Boulogne-sur-Mer**, a fortified seaport, in the department of Pas-de-Calais is situated on the shore of the English Channel, at the mouth of the river Liane, in lat. 50° 44' N., lon. 1° 33' E., 157 m. from Paris. The entrance to the harbor of *B.*, which is tidal, is formed by two long piers running out from the mouth of the river, and serving during fine weather as excellent promenades. On the western side is the basin excavated by Napoleon for his flotilla of flat-bottomed boats in 1804. A large wet dock, constructed at a cost of upwards of

\$1,250,000, was opened in 1872, and adds greatly to the facilities of the port, its area being 17 acres and the length of its quay-wall 1,150 yards. The depth of water in the harbor is 23 feet at spring-tide and nearly 20 at neap-tide. In the sluice of the floating basin the numbers are 231 and 233 respectively. The foreign commerce of *B.* consists chiefly in the importation of manufactured goods, jute, silk, Australian wool, coal, machinery, hardware, paper hangings, malt, beer, and chemicals; and the exportation of wine, brandy, eggs, artificial flowers, haberdashery, and musical instruments. The total value of the exports in 1878 was \$67,884,070, and of the imports, \$61,068,000. In the value and extent of its fisheries *B.* is exceeded by no seaport in *F.* The most important branch is the herring-fishery, which is prosecuted northwards along the shores of Scotland; next in value is the mackerel-fishery, and next again the Iceland cod. *B.* has for a long time been one of the most Anglicized of French cities; and in the tourist season a continuous stream of English travellers reach the Continent at this point. There is regular steamboat service between the port and Folkestone, the average passage occupying 2½ hours, or about three quarters of an hour longer than from Calais to Dover. Pop. 49,055.

**Brest** is a strongly fortified maritime town in the department of Finistère, on the N. side of a spacious and magnificent land-locked bay, near the extremity of the peninsula of Brittany, 310 m. W. S. W. of Paris, in lat. 48° 23' 32" N., lon. 4° 29' 25" W. It occupies the slopes of two hills, divided by the river Penfeld, the part of the town on the left bank being regarded as *B.* proper, while the part on the right is known as Recouvrance, from the chapel of the Virgin, to whom the shipwrecked sailors used to address their prayers for the recovery of their property. The harbor, situate between *B.* and Recouvrance, is in the form of a long canal, and is capable of containing 60 ships of the line. The great convict establishment, which formerly held some 3,000 convicts, was vacated in 1890, and is now used as a storehouse. The government naval arsenal and dockyard are very extensive, and the *H. pital de la Marine* contains 26 wards, each with 53 beds. The manufactures are few, and the trade is of small extent considering the excellence of the ports, being principally limited to the supplying of provisions to the town and military post. Pop. 66,828.

**Calais** is a fortified seaport town in the department of Pas-de-Calais, 22½ m. E. S. E. of Dover, and 185 m. from Paris, in lat. 50° 57' 45" N., lon. 1° 51' E. The harbor is shallow, admitting vessels from 400 to 500 tons only at high water. There are two lighthouses at the entrance of the harbor, and a still larger one on the fortifications, with a revolving light visible 20 miles off. The imports are chiefly from Great Britain. The manufacture of *tulle*, or bobbinet, is one of the main sources of prosperity of the town and suburbs. Steamers carrying the mails cross twice a day to Dover and back. It is the principal landing-place for English travellers on the Continent. The terminus of the proposed tunnel beneath the Channel is near Sangatte, a village 6 m. W. of *C.* The project has received the sanction of the French and English governments. Pop. 19,843.

**Cette**, in lat. 43° 24' N., lon. 3° 42' E., is situated in the department of Hérault, on the narrow strip of land which separates the étang or lagoon of Thau from the sea, 15 m. S. W. of Montpellier. It forms one embouchure of the Great Canal of Languedoc, a circumstance to which its rise and prosperity is alone attributable, as the port is not very good, nor has it the natural facilities for becoming so; it has also a canal communication with the Rhone. The harbor, which has from 15 to 19 feet water, and can accommodate about 400 vessels, is formed by two lateral moles, with a breakwater across the entrance. The moles are fortified, and on the principal one is a lighthouse, elevated 84 feet above the level of the sea. A considerable trade is carried on in the wines and brandies of Languedoc, of which *C.* is the depot. The salt-works on the adjoining lagoon are pretty extensive, as are also the fisheries, particularly that of sardines. *C.* has regular steam-communication with Algiers, and the chief ports on the E. coast of Spain. About 150,000 tons of shipping (including coasters) enter annually. Pop. 28,152.

**Cherbourg** is a strongly fortified seaport town, and one of the principal naval depots of *F.*, in the department of the Manche, in lat. 49° 43' 9" N., lon. 1° 35' W., at the bottom of a bay formed by Cape Lévi on the E. and Cape La Hague on the W., at the mouth of the Divette, 185 m. W. N. W. of Paris. Its principal interest is derived from its arsenal and fortifications. From its advanced position in the English Channel, it has long been a favorite object with the French government to render *C.* a great naval stronghold, and a secure asylum for ships of war; and, to accomplish this, vast sums have been expended upon it. The harbors for merchantmen and vessels of war are quite distinct from each other. The latter, which was constructed by Napoleon I., is a magnificent work, excavated out of the solid rock. It is 328 yards long by 250 wide, and capable of accommodating 50 sail of the line, which may enter at will, there being 25 feet of water at low ebb. There are, besides, 4 superb graving-docks, and a basin. Near the naval port is the great and extensive dockyard, etc. The roadstead of *C.* is one of the best in the channel, and capable of contain-

ing 400 sail. It is defended on all sides by batteries, and further protected from N. winds and heavy seas by a massive breakwater, commenced in 1784, and finally completed by Napoleon III., in 1864. Its length is 4,120 yards; breadth at base, 262 feet, and at its summit 101 feet. On its central part a battery is erected. As a commercial port, C. is of comparatively small importance. Pop. 36,338.

**Dieppe** is a seaport town of the department of Seine-Inférieure, at the mouth of the Arques, on the English Channel, 33 m. N. of Rouen and 92 m. N. W. of Paris. The port, enclosed by two jetties and bordered by quays, can accommodate from 60 to 80 vessels under 600 tons; but it dries at low water, and it is otherwise inconvenient. D. has an active general trade, ship building docks, manufactories of ivory-ware, watches, lace, etc., and it is a packet station, communicating daily by steamboats with Newhaven, England. D. is also largely concerned in the herring, mackerel, and oyster fisheries. It is a favorite seaside resort. Pop. 19,946.

**Dunkirk** [*Fr. Dunkerque*], a strongly fortified seaport in the department of Nord, is on the Straits of Dover, 194 m. N. from Paris, in lat.  $51^{\circ} 2' N.$ , lon.  $2^{\circ} 22' 32'' E.$  It is divided into three parts: the town proper, which is the centre of trade; the low town, containing the principal industries; and the citadel, including docks and granaries, and containing the houses of laborers and sailors. D. is both a naval port and one of the merchant ports of Paris, and has two harbors, its maritime trade employing about 5,000 vessels, with a tonnage

consumption are imported thither. Nearly double the quantity of goods, estimated by weight, is annually imported at Marseilles; but the total value of the imports at Havre amounts very nearly to that of those at the former port. The principal imports are cotton, sugar, coffee, linen thread and linen goods, rice, indigo, tobacco, hides, dyewoods, spices, drugs, timber, iron, tin, dried fish, grain and flour from the U. States, etc. H. receives the  $\frac{1}{2}$  of the cotton imported into F., and is in this respect to F. what Liverpool is to England. The principal exports are silks, woollen and cotton stuffs, lace, gloves, and shoes, trinkets, perfume, champagne and other wines, brandy, glass, furniture, books, etc. H. is to the N. of F. what Marseilles is to the S., to which it is second in the number of its mercantile marine. Besides the navigation of the Seine, H. is connected with Paris by lines of railroad, and is visited annually by about 3,000 vessels engaged in the foreign trade, and about 3,500 coasting vessels. Lines of sailing ships are established between H. and New York, New Orleans, etc. A regular intercourse is kept up with New York by means of steamers of the *Compagnie Transatlantique*, which is here located, and of the German line of Hamburg, which has a station at H. Most of the goods imported into H. are destined for the internal consumption of F. The coasting and the foreign trades are of considerable importance, and are steadily increasing. The harbor, which takes in ships drawing 24 feet at all tides, consists of 3 basins separated from each other and from the outer port by 4 locks. A large body of water being

Fig 208. — MONT ST. MICHEL.

of 270,000. The docks occupy about 100 acres. It possesses sugar-refineries, starch-manufactories, distilleries, foundries, and large ship-building yards. The fisheries of the coast are valuable and extensive. Pop. 35,012.

**Fécamp**, a seaport town in the department of Seine-Inférieure, is situated on the English Channel, at the mouth of a small cognominal river 23 m. N. N. E. of Havre. It occupies the bottom and sides of a narrow valley opening out towards the sea, between two cliffs, on one of which stands a lighthouse. Its port, though small, is one of the best on the Channel, and has been greatly improved by the construction of an inner port with a fine quay, etc. It carries on a considerable trade in Baltic and colonial produce, brandy, salt, etc.; and sends out vessels to the whale, cod, mackerel, and herring fisheries. In 1878 there entered 178 vessels, with a total tonnage of 27,167. The river affords abundant water-power for numerous cotton, oil, and other mills. Fécamp has also sugar refineries, tanneries, building-docks, and manufactures of hardware, candles, soda, etc. Pop. 12,651.

**Havre, or Le Havre**, is the principal commercial seaport on the W. coast of F., in the department of Seine-Inférieure, on the English Channel, near the mouth of the Seine, on its northern bank, 109 m. W. N. W. of Paris, in lat.  $49^{\circ} 29' 14'' N.$ , lon.  $0^{\circ} 6' 38'' E.$  It was a saying of Napoleon I. that "Paris, Rouen, Le Havre, ne forment qu'une seule ville, dont la Seine est la grande rue." H. being, in fact, the seaport of Paris, most of the colonial and foreign products destined for its

retained by a sluice and discharged at ebb-tide, clears the entrance to the harbor, and prevents the accumulation of filth, sand, etc. Cape de la Heve, forming the northern extremity of the Seine, lies N. N. W. from Havre, distant about  $2\frac{1}{2}$  m. It is elevated 390 feet above the level of the sea, and is surmounted by 2 lighthouses 50 feet high. These, which are 325 feet apart, exhibit powerful fixed lights. There is also a brilliant harbor light at the entrance to the port, on the extremity of the western jetty. H. has 2 roadsteads. The greater or out road is about a league from the port, and rather more than  $\frac{1}{2}$  league W. S. W. from Cape de la Heve; the little or inner road is about  $\frac{1}{2}$  league from the port, and about  $\frac{1}{4}$  of a mile S. S. E. from Cape de la Heve. They are separated by the sandbank called *Leclat*, between which and the bank called *Les Hautes de la Rade* is the N. W. passage to the port. The Hoc, or S. passage, lies between the last-mentioned bank and that of Amfar. In the great road there is from 6 to  $7\frac{1}{2}$  fathoms water at ebb; and in the little, from 3 to  $3\frac{1}{2}$ . Large ships always lie in the former. The rise of the tide is from 22 to 27 feet; and by taking advantage of it the largest class of merchantmen enter the port. The water in the harbor does not begin perceptibly to subside till about 3 hours after high water, — a peculiarity ascribed to the current down the Seine across the entrance to the harbor being sufficiently powerful to dam up for a while the water in the latter. Large fleets, taking advantage of this circumstance, are able to leave the port in a single tide, and get to sea, even though the wind should be unfavor-

able. — There belonged to the port, in 1876, 422 merchant-vessels, of the aggregate burden of 149,211 tons. Pop. 85,417.

**Pilotage.** From the outer roadstead 28 francs per 1st 100 tons; 25 francs 21 do.; 23 francs 31 do.; and the pilot to be fed. If the vessel be boarded nearer the port, the charge is lessened accordingly. Boats, from 9 to 50 francs, according to the distance.

**Harbor Rules.** 1. It is forbidden to have fire, or lighted candle, or to smoke on board ships in the harbor. 2. Vessels coming into and lying in the docks must have the lower and topyards topped up, jib-booms and martingales rigged in, and anchors taken in. The wharf alongside the vessel must be swept every evening. 3. No gunpowder (whatever may be the quantity), is allowed to remain on board, and must be deposited in the gunpowder warehouse. 4. All foreign sailors found away from their ships after 10 o'clock at night, from the 1st of April to the 1st of October, and after 9 o'clock from the 1st of October to the 1st of April, shall be conveyed to prison and fined. Sailors are forbidden to wear sheathing-knives ashore. 5. The manifest of the cargo, signed by the captain, must be exhibited to and signed by the custom-house officers before being taken ashore. The vessel must be reported at the custom-house within 24 hours after arrival. 6. Tobacco, snuff, segars, loose or in boxes, belonging to the captain, officers and mariners to be declared as exactly as possible. All the tobacco, snuff, and segars declared or not declared, to be exhibited to the custom-house officers when they come and make the visit on board. After such exhibition, if any quantity of tobacco and segars be found on board, it shall be seized, the captain shall be condemned to pay a fine which may be as high as 500 francs, and the ship shall be confiscated.

**La Rochelle** is a fortified seaport of the department of Charente-Inférieure, on an islet of the Bay of Biscay, formed by the islands Ile and Oleron, 30 m. N. W. of Paris. The inner harbor, which has two basins, in which ships of any size may remain afloat, is surrounded by fine quays and commodious docks, close to which lie the principal streets and squares. The principal exports are wine and brandy. Pop. 15,547.

**Lorient** is a seaport of the department of Morbihan, at the confluence of the Scorff with the Blavet, at the head of the Bay of Port Louis, about 3 m. from the Atlantic, and 29 N. W. of Vannes. The harbor is ample, secure, and of easy access, and bordered by fine quays, on which are large and commodious buildings. Like Brest, it is a natural dockyard; as a port of war it ranks third, and as a port of construction it ranks first. More ships of war are now built at Lorient than at any other port in F. Its trade is chiefly coastwise. Pop. 37,655.

**Marseille** [*Vr. Marseille*] is a large commercial city and the chief seaport of F., capital of the department of Bouches-du-Rhône, on the E. side of a bay of the Gulf of Lyons, 429 m. S. E. of Paris, in lat. 43° 17' 49" N., lon. 5° 22' E. It is situated in the centre of a plain about 7 m. broad, bounded by lofty hills extending in the form of a crescent until each extremity reaches the sea. The port consists of the natural harbor, called *Vieux Port*, and the two basins formed within the breakwater, called respectively *Port de la Joliette* and *Port Napoleon*. The *Vieux Port*, about 1,400 yards long and 300 wide, has a very narrow entrance between two old forts, but is one of the safest ports in the world. Dredging-machines are constantly at work to maintain a uniform depth of about 18 feet throughout the Old Port, which is exclusively reserved for sailing ships, which usually lie in tiers on the N. and S. sides, and mostly discharge their cargoes over their bows on to the quays. A breakwater, 2,400 metres long, lies off the land on the N. side of the Old Port, and has a lighthouse on each end. A vessel on rounding the S. entrance of this breakwater enters the port of La Joliette to the left, a basin about 600 yards long by about 140 wide. It is surrounded on all sides by spacious quays, and furnished with iron tramways for the conveyance of merchandise in railway trucks to the dock buildings and railway station. La Joliette is used for steam as well as for sailing vessels of considerable draught of water; the whole N. and about half the W. sides being reserved for the fleet of steamships belonging to the *Messageries Nationales*. An opening with a turning bridge leads from La Joliette to the Port Napoleon, which is considerably more spacious than the former. On its E. side there are two basins, *du Lazaret* and *d'Arcen*, with spacious quays for the whole. In this harbor the ships lie broadside on to the wharves, and discharge their cargoes. The great dock warehouses form a range of buildings of stone and iron, six stories high, and capable of containing 40,000 tons of general merchandise. In both of these artificial ports there is ample depth of water for the largest ships, but unfortunately neither of them is very safe when the wind blows violently from the N. W. or N. E. The whole, including the old harbor, would contain at one time as many as 2,000 vessels. The isles of Rattoneau and Pomegues, and that named after the celebrated Chateau d'If, all fortified, lie in a cluster off the port, the latter distant about 1½ m. in a W. S. W. direction. Rattoneau and Pomegues are connected by a breakwater, and thus form a very convenient port, almost exclusively used for the quarantine service. Outside of these islands lies a reef with a lighthouse called *Le Phare* in lat. 43° 11' 51" N., lon. 5° 13' 59" E. It is distant about 4½ m. from the island Le Maire, lying to the E. of it, both of them being about 7 m. from the

Chateau d'If. The custom-house is on the quay of the Old Port, and there is a branch at Port de la Joliette, principally for the examination of passengers' luggage. The Tribunal of Commerce sits in the Exchange, and the judges are periodically elected from amongst the leading merchants. All the principal mercantile offices are near the head of the Old Port. Vessels approaching the harbor of M. generally heave to for a pilot on approaching the islands, and they are charged pilotage whether they take one or not. French ships and foreign vessels having reciprocity treaties, upwards of 80 tons burden, pay for pilotage 22 centimes per ton inwards, and 15 outwards. If the pilot is taken on board 6 or 7 m. off the port, the full charge is paid; it is reduced 4 if he comes on board 2 or 3 m. off, and 4 if he comes on board at the entrance of the port. Immediately on receiving pratique, the ship is taken to the old or new harbor, according to the nature of the cargo she has on board, or the goods she may have to take in. The only charge leviable on ships visiting M. consists of a small payment at the health office for the bill of health. It amounts to from 5 to 15 centimes per ton. There are no tonnage, anchorage, or light dues of any sort. Ballast is at once paid for. Vessels can be well repaired at M., but the charges are high. The charges for docking are as follows:—

#### Sailing Ships.

	Francs.	Centimes.
Entering into and leaving the dry dock on the same day, per ton, .....	0	40
For every day beyond the first day and per ton ..	0	80

#### Steamships.

	Francs.	Centimes.
Entering into and leaving the dry dock on the same day, per horse power, .....	4	0
For every day beyond the first day and per horse-power .....	2	0

No payment will be received on any sailing vessel for less than 250 tons. No payment will be received on any steam-vessel for less than 60 horse-power. Upon steam-vessels whose horse-power exceeds that of 250 horses, the prices above mentioned will be reduced  $\frac{1}{4}$  for every horse-power above the 250 first and up to 400, and  $\frac{1}{2}$  for all beyond the first 400. For sailing ships upwards of 1,000 tons, the foregoing prices will be reduced  $\frac{1}{4}$  for every ton above the first 1,000 and up to 1,500, and  $\frac{1}{2}$  for every ton above 1,500. — The Rules of the harbor are the same as those enforced in the port of Havre, and given above. — The approaches to the port are admirably lighted, and the service is kept up without any charge to the shipping. The different lights in the bay or at the entrance of the port are described at the end of this article. The mistral, or N. W. wind, is the prevailing one; it blows in very heavy gusts, which render the approach to the port of M. exceedingly difficult at times, and vessels rarely leave the port until it subsides.

M. is a city of great antiquity, and has long enjoyed a very extensive commerce. It is the grand emporium of the S. of France, and the centre of  $\frac{2}{3}$  of its commerce with the countries to the Mediterranean and Black Seas. The exports consist principally of silk stuffs, wines, brandies, and liquors; woollens and linens; madder, oil, soap, refined sugar, perfumery, stationery, verigris, and all sorts of colonial products. Among the principal imports are sugar, coffee, and other colonial products; dyestuffs; corn from the Black Sea and the N. coast of Africa; cotton from Egypt and America; coal, linen, thread, and various descriptions of manufactured goods from England; with hides, wool, tallow, timber, etc. M. engrosses almost the whole trade between France and Algiers. It is now also the principal seat of the intercourse carried on by steamers with Malta, Alexandria, and Constantinople, and besides the steamers employed by the government as packets, it ran upward of 40 steamers belonging to private companies. In 1877 there belonged to the port 895 sailing and steam vessels of the burden of 153,714 tons. In 1878, 42 American vessels (tonnage 29,737) entered, and 24 (tonnage 16,494) cleared the port. The manufactures of M. are very important and various. The most important are soap, coral articles, silk stuffs, woollens, cottons, linens, hats, leather, sail clothes, china, alum, sulphur, vitriol, salt, etc. There are, besides, refineries for sugar, and manufactures of vinegar and liquors. Another branch of industry is the pickling and preparing for exportation of capers, olives, and other fruits, as well as large quantities of fish. It has also a great variety of trades connected with the building and fitting out of ships and steamers. Pop. 231,380.

**Nantes**, an important city and seaport, capital of the department of Loire-Inférieure, is situated on the Loire, about 34 m. from its mouth, 210 m. S. W. of Paris, in lat. 47° 13' 6" N., lon. 1° 32' 41" W. Its situation renders N. the emporium of all the rich and extensive country traversed by the Loire, so that it has a pretty considerable import and export trade, particularly with the West Indies. The exports consist of all sorts of French produce, but principally of brandy, wine, and vinegar, silk, woollen, and linen goods, refined sugar, wheat, rye, and other kinds of grain, biscuits, sailines, preserves, etc. The principal imports are sugar, coffee, and other

colonial products, cotton, indigo, timber, hemp, etc. N is a considerable entrepôt for the commerce of salt, large quantities being made in the department, principally at Noirmoutier and Croisic. No vessel drawing more than 11 or 12 feet can come up to the city, unless at high water a day or two before *full and change*. Vessels drawing 18 or 19 feet water come up to Palumbo, about 24 m. lower down the river. Larger ships either remain at St. Mazaire, at the mouth of the river, or at least discharge part of their cargo there. There are three entrances to the Loire. The first and most generally frequented is between the bank called *Le Four* and *Point Croisic*; there is a second between *Le Four* and the bank called *La Banche*; and a third, which in southerly winds is much resorted to, between the latter and the rocks, called *La Couronne*. The navigation, which is naturally rather difficult, has been much facilitated by the erection of lighthouses and beacons. The depth of water on the bar at the mouth of the river varies from 2 to 2½ fathoms. At springs the rise is 14, and at neaps, 7 or 8 feet. High water at full and change 3½ hours. In 1877 there belonged to the port of N, ex-river craft, coasters, and steamers, 763 ships, of an aggregate burden of 147,851 tons. N is the second port in F. for commercial shipping. The city, with its magnificent quays, its splendid river dotted with islands, its handsome bridges spanning its surface and uniting its different parts, the harbor of Lafose, its lofty edifices, its crowd of shipping of all rig and nations, and its miles of lawn-like meadows stretching far away on either bank of the Loire and Erdre, produces a *coup d'œil* of beauty, magnificence, and prosperity, not to be surpassed by any other city in France. Pop. 116,063.

**Nice** is a city and seaport in the department of Alpes Maritimes, on the Mediterranean, 95 m. S. W. of Genoa. It is beautifully situated at the foot of the Alps, which protect it from the N. and E. winds. Owing to its genial climate, it is a resort for invalids from all parts of Europe during the winter months. The port is small, but is convenient for vessels of 300 tons burden. The principal exports are oil, wine, oranges, and hemp. Pop. 46,683.

**Rochefort** is a seaport and naval arsenal in the department of Charente-Inférieure, on the Charente, 5 m. from its mouth, and 18 m. S. E. of La Rochelle, in lat. 45° 53' 6" N., lon. 1° 57' 7" W. It is the third military port of F. in importance, and contains numerous public works, but its foreign trade is little. Pop. 25,454.

**St. Mulo** is a seaport town of the department of Ille-et-Vilaine, on the British Channel, 200 m. S. W. of Paris. It is built on the peninsula of Aron, connected by a causeway with the mainland, and strongly fortified. The port on the S. side is commodious and secure, but rather difficult of entrance. *Manuf.*, rope, fishing-nets, blocks, and other marine fittings. It has a considerable trade in provisions with the French colonies, a brisk coasting-trade and numerous vessels engaged in the mackerel, cod, and whale fisheries. Pop. 12,000.

**Toulon** is the second naval port of F. in importance, in the department of Var, at the bottom of one of the finest harbors of the Mediterranean, 32 miles E. S. E. of Marseilles, and 190 m. S. E. of Lyons, in lat. 43° 7' 5" N., lon. 5° 56' E. The town is strongly fortified, being surrounded by a double rampart, and a large and deep ditch, defended to the E., W., and N. by hills covered with redoubts. Both the old and new harbors are artificial. The latter, formed by hollow and bomb-proof jetties running off from the E. and W. sides of the town, is sufficiently extensive to accommodate 30 sail of the line, as many frigates, and an equal proportion of small craft. The entrance is shut by a boom, and it is never ruffled by any wind to occasion damage. The arsenal of T. is one of the finest in Europe. The *Bagne*, instituted in 1682, is, from want of room on shore, established on board some hulks; it is occupied by criminals condemned to hard labor for ten years and under. The foreign trade of the port is inconsiderable. Pop. 61,332.

**Frangipane**, a perfume of jasmine.

**Frangote**, a bale of goods in Spain.

**Frankfort-Black**, a pigment said to be prepared by burning vine-branches, grape-stones, and the refuse lees of the wine manufacture, etc., used for copperplate printing.

**Frankincense**, a name for the gum olibanum of commerce, an odoriferous resin obtained from several species of *Boswellia*. The European frankincense is a resinous exudation from the spruce fir, and is used in the composition of plasters.

**Franking**, a carpenter's term for window-sashes in which the cross-pieces of the frame intersect each other.

**Franklin**, a fire-insurance Co., located in Boston, Mass., organized in 1873. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$200,000; net surplus, \$7,980.31; total cap. and surplus, \$207,980.31; risks in force, \$7,346,961; premiums, \$87,715.11; premi-

ums received since the organization of the Co., \$604,559.85; losses paid, \$291,461.95; cash dividends paid to stockholders, \$66,000.

**Franklin**, a fire-insurance Co. located in New York City, organized in 1876. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$200,000; risks in force, \$4,512,819; premiums, \$30,741.83; premiums received since the organization of the Co., \$268,067.78; losses paid, \$159,528.21.

**Franklin**, a fire-insurance Co., located in Philadelphia, Pa., organized in 1829. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$400,000; net surplus, \$960,476.32; total cap. and surplus, \$1,360,476.32; risks in force, \$142,867,352; premiums, \$2,561,774.19; premiums received since the organization of the Co., \$19,866,252.51; losses paid, \$11,088,837.23; cash dividends paid to stockholders, \$3,708,000.

**Franklinite**, an ore of iron, zinc, and manganese.

**Frasco**, the name of a flask or case bottle in Brazil, containing about 3½ pints.

**Fraud**, a dishonest transaction; adulteration, deception; a cheat, etc.

**Fray**, to fret or rub; to unweave.

**Frazil**, **Frazli**, the Arabian name for a bale of variable weight, ranging from 18½ lbs. to 30 lbs.

**Frederick d'or**, an old gold coin of Prussia, worth about \$4.

**Freeboard**, that part of a vessel's side which is included between the plank-sheer and the water-line.

**Freebord**, ground outside a fence.

**Free Goods**, goods which are admitted into a country free of duty.

**Free-Martin**, a heifer incapable of breeding; the barren twin calf whose mate is a bull calf.

**Free on Board**. See F. O. B.

**Free Port**, a port or harbor where goods may be landed, warehoused, and exported free of custom-duty.

**Freestone**, is not in itself a particular kind of stone, but is the name given by the quarryman and the mason to any stone which, having no grain, works freely under the tools. The name applies to some kinds of limestone as well as to some of sandstone.

**Free-Trade**. See PROTECTION AND FREE TRADE.

**Free Vintner**, in England, a member of the vintners' company; one who can sell wine without a license.

**Freezer**, an apparatus for freezing cream, fruits, or water ices, of which there are many kinds. They substantially consist of a metallic cylinder containing the liquid to be cooled or congealed, enclosed by another cylinder, and surrounded by the freezing mixtures. The machine is rotated (Fig. 209) or oscillated to thoroughly agitate the liquids, and bring new particles to the cold surface. The *freezing mixture* commonly used consists of ice broken small, and mixed with about half its weight of common salt.

**Freight** is the sum paid by the merchant or other person hiring a ship, or part of a ship, for the use of such ship or part during a specified voyage or for a specified time. The *F.* is most commonly fixed by the charter-party or bill of lading, but in the absence of any formal stipulations on the subject, it would be due according to the custom or usage of trade. In the case of a charter-party, if the stipulated payment be a gross sum for an entire ship, or an entire part of a ship, for the whole voyage, the gross sum will be payable, although the merchant has not fully laden

the ship; and if a certain sum be stipulated for every ton, or other portion of the ship's capacity, for the whole voyage, the payment must be ac-

Fig. 209. — PACKER'S DOUBLE-ACTION FREEZER.

ording to the number of tons, etc., which the ship is proved capable of containing, without regard to the quantity actually put on board by the merchant. On the other hand, if the merchant have stipulated to pay a certain sum per cask or bale of goods, the payment must be, in the first place, according to the number of casks and bales shipped and delivered; and if he have further covenanted to furnish a complete lading, or a specific number of casks or bales, and failed to do so, he must make good the loss which the owners have sustained by his failure. If an entire ship be hired, and the burden thereof be expressed in the charter-party, and the merchant bind himself to pay a certain sum for every ton, etc., of goods which he shall lade on board, but does not bind himself to furnish a complete lading, the owners can only demand payment for the quantity of goods actually shipped. But if the merchant agree to load a full and complete cargo, though the ship be described as of less burden than she really is, the merchant must load a full cargo, according to the *real burden* of the ship, and he will be liable for *F* according to what ought to be loaded. — The delivery of goods at the place of destination is in general necessary to entitle the owner to *F*; but with respect to living animals, which may frequently die during the voyage without any fault or neglect of the persons belonging to the ship, it is ruled that if there be no express agreement whether the *F* is to be paid for the lading or for the transporting them, *F* shall be paid as well for the dead as for the living; if the agreement be to pay *F* for the *lading*, then death certainly cannot deprive the owners of the *F*; but if the agreement be to pay *F* for *transporting* them, then no *F* is due for those that die on the voyage, because as to them the contract is not performed. These distinctions have been made in the civil law, and have been adopted into the modern systems of maritime law. — *F* is most frequently contracted to be paid either by the whole voyage, or by the month, or other time. In the former case the owners take upon themselves the chance of the voyage being long or short; but in the latter the risk of the duration falls upon the merchant; and if no time be fixed for the commencement of the computation,

it will begin from the day on which the ship breaks ground and commences her voyage, and will continue during the whole course of the voyage, and during all unavoidable delays *not occasioned by the act or neglect of the owners or master*, or by such circumstances as occasion a suspension of the contract for a particular period. Thus, the *F* will be payable for the time consumed in necessary repairs during a voyage, provided it do not appear that the ship was insufficient at the outset, or that there was any improper delay in repairing her. In the absence of an express contract to the contrary, the entire *F* is not earned until the whole cargo be ready for delivery, or has been delivered to the consignee according to the contract for its conveyance. — If a consignee receive goods in pursuance of the usual bill of lading, by which it is expressed that he is to pay the *F*, he, by such receipt, makes himself debtor for the *F*, and may be sued for it; but a person who is only an agent for the consignor, and who is known to the master to be acting in that character, does not make himself personally answerable for the *F* by receiving the goods, although he also enters them in his own name at the custom house. — In some cases *F* is to be paid, or rather an equivalent recompense made to the owners, although the goods have not been delivered at the place of destination, and though the contract for conveyance be not strictly performed. Thus, if part of the cargo be thrown overboard for the necessary preservation of the ship and the remainder of the goods, and the ship afterwards reach the place of destination, the value of this part is to be answered to the merchant by way of general average, and the value of the *F* thereof allowed to the owner. So, if the master be compelled by necessity to sell a part of the cargo for victuals or repairs, the owners must pay to the merchant the price which the goods would have fetched at the *place of destination*, and therefore are allowed to charge the merchant with the money that would have been due if they had been conveyed thither. — When goods are deteriorated during a voyage, the merchant is entitled to a compensation, provided the deterioration has proceeded from the fault or neglect of the master or mariners; and of course he is not answerable for the *F*, unless he accept the goods, except by way of deduction from the amount of the compensation. On the other hand, if the deterioration has proceeded from a principle of decay naturally inherent in the commodity itself, whether active in every situation, or in the confinement and closeness of a ship, or from the perils of the sea, or the act of God, the merchant must bear the loss and pay the *F*; for the master and owners are in no fault, nor does their contract contain any insurance or warranty against such an event. *F*, being the return made for the conveyance of goods or passengers to a particular destination, no claim arises for its payment in the event of a total loss. In case of a total loss with salvage, the merchant may either take or abandon the part saved, but after the merchant has made his election he must abide by it. — It frequently happens that the master or owner fails to complete his contract, either by not delivering the whole goods to the consignee or owner, or by delivering them at a place short of their original destination; in these cases, if the owner or consignee of the goods *derive any benefit from their conveyance*, he is liable to the payment of *F* according to the proportion of the voyage performed; and though contracts of this nature be frequently entire and indivisible, and the mas-

ter or owner of the ship cannot, from their nature, sue thereon, and recover a ratable freight, yet he may do so upon a fresh implied contract, for as much as he deserves to have, unless there be an express clause in the original charter-party or contract to the contrary. A fresh implied contract is inferred from the owner's or consignee's acceptance of the goods. Many difficulties have, indeed, arisen in deciding as to what shall amount to an acceptance: it is not, however, necessary actually to receive the goods; acceptance may be made by the express or implied directions, and with the consent of the owner or consignee of the goods, but not otherwise. — The time and manner of paying *F.* are frequently regulated by express stipulations in a charter-party, or other written contract; and when that is the case they must be respected; but if there be no express stipulation contrary to or inconsistent with the right of *lien*, the goods remain as a security till the *F.* is paid; for the master is not bound to deliver them, or any part of them, without payment of the *F.* and other charges in respect thereof. But the master cannot detain the cargo on board the vessel till these payments be made, as the merchant would, in that case, have no opportunity of examining the condition of the goods. In this country, the practice is, when the master is doubtful of payment, and that *F.* is not paid in the 24 hours of the landing, to send such goods to a public warehouse, ordering the warehouseman not to part with them till the *F.* and other charges are paid. No right of *lien* for *F.* can exist unless the *F.* be earned; if the freighter or a stranger prevent the *F.* from becoming due, the ship owner or master's remedy is by action of damages.

**Freighter**, he to whom a ship or vessel has been hired.

**Fremont, Elkhorn, and Missouri Valley R.R.** runs from Fremont to mouth of Niobrara River, Neb., 150 m., of which only 51.13 m., from Fremont to Wisner, Neb., are at present in operation, and leased under temporary contract to the Sioux City and Pacific R.R. Co. for 33 $\frac{1}{3}$ % of gross earnings. The Co.'s offices are in Cedar Rapids, Ia. *Financial statement*: Cap. stock paid in, \$690,000; funded debt, 1st mortgage 7% bonds, issued 1871, \$690,000, payable 1901, interest April and October.

**French-Bean**, a dwarf variety of the *Phaseolus vulgaris*, or common bean.

**French-Berries**, berries used in dyeing. See AVIGNON-BERRIES.

**French-Chalk**, indurated talc; a magnesian mineral used to remove grease, stains, etc.

**French-Horn**, a musical wind-instrument of copper, having several curves. See HORN.

**French Leaf**, a kind of bronze leaf composed of copper and zinc, the proportion of zinc being larger than in the common Dutch leaf, and less than in the Florence leaf, and of a yellow color.

**French Polish**. Several varnishes for furniture are used under this name. That most generally employed is a simple solution of 5 $\frac{1}{2}$  oz. pale shell-lac in one pint of the finest wood naphtha. Sometimes a little mastic, sandarac, or elemi, or copal varnish is added to render the polish tougher. Sometimes, also, it is colored, in order to modify the character of the wood. A reddish tinge is given with dragon's blood, alkanet root, or red sanders wood; and a yellowish tinge, by turmeric root or gamboge. When it is simply desired to darken the wood, brown shell-lac is employed to make the polish; and when the object is to keep the wood light colored, a little oxalic acid (2 to 4 dr. to the

pint) is commonly added. These substances are either steeped in or agitated with the polish, or with the solvent, before pouring it on the "gums," until they dissolve, or a sufficient effect is produced. French polish is not required to be so clear and limpid as other varnishes, and is, therefore, never artificially clarified.

**French Polishing**. This process, now so generally employed for furniture and cabinet work, is performed as follows: The surface to be operated on being finished off as smoothly as possible with glass paper, and placed opposite the light, the "rubber" being made as directed below, and the polish (see above) being at hand, and preferably contained in a narrow-necked bottle, the workman moistens the middle or flat face of the rubber with the polish, by laying the rubber on the mouth of the bottle and shaking up the varnish against it, once, by which means the rubber inhibits the proper quantity to cover a considerable extent of surface. He next encloses the rubber in a soft linen cloth, doubled, the rest of the cloth being gathered up at the back of the rubber to form a handle. The face of the linen is now moistened with a little raw linseed-oil, applied with the finger to the middle of it, and the operation of polishing immediately commenced. For this purpose the workman passes his rubber quickly and lightly over the surface, uniformly in one direction, until the varnish becomes dry, or nearly so, when he again charges his rubber as before, omitting the oil, and repeats the rubbing until three coats are laid on. He now applies a little oil to the rubber, and two coats more are commonly given. As soon as the coating of varnish has acquired some thickness, he wets the inside of the linen cloth, before applying the varnish, with alcohol, or wood naphtha, and gives a quick, light, and uniform touch over the whole surface. The work is, lastly, carefully gone over with the linen cloth, moistened with a little oil and rectified spirit or naphtha, without varnish, and rubbed, as before, until dry. — The rubber is made by rolling up a strip of thick woollen cloth (dist) which has been torn off, so as to form a soft elastic edge. It should form a coil, from 1 to 3 inches in diameter, according to the size of the work.

**French Sand**, a silicious mineral imported from France, and used in the manuf. of glass.

**French White**, pulverized talc; carbonate of lead.

**French Wine**. See BURGUNDY, CHAMPAGNE, CLARET, etc.

**Frequin**, a cask used in France for holding sugar or treacle.

**Fresco**. This Italian word means *fresh*; and *fresco-painting* consists in painting upon fresh or wet plaster. When the rough plaster-work of a wall is finished, a surface of fine, smooth plaster is given to it. While this surface plaster is still wet, the artist paints upon it with mineral colors mixed with water. Only as much of the surface is plastered as can be painted the same day, while the surface remains sufficiently damp. There are many difficulties connected with the art, — to make the joinings in successive days' work invisible; to insure that the color on the wet plaster shall present the proper tints when the plaster is dry; and to produce a peculiarity of surface due to the line when the plaster dries properly.

**Fret**, to fray; to unweave. — In French, the hire of a ship; the cargo; the sum paid for the transport of goods; the freight.

**Frett**, a glass composition, composed of silica, lime, soda, borax, and lead, used as a glaze by potters.

**Fretwork**, carved or open wood-work, in ornamental devices and patterns.

**Friar**, in printing, a pale patch in a printed sheet.

**Friar's-Balsam**, a specific for wounds, popular in England. It is an alcoholic solution of benzoin, styrax, tolu balsam, and aloes.

**Frickle**, a bushel-basket.

**Friction**, in a general sense, the act of rubbing one body against another; attrition. — In mechanics, the resistance which the surface of a moving body meets with from the surface of the body on which it moves. The *F.* between two surfaces

varies greatly according to the material, although the perfection of workmanship may be quite equal. In oak upon cast-iron, the *F.* is greater than for brass upon cast-iron; while wrought-iron on wrought-iron is the greatest of the three. Generally speaking, two similar substances have more *F.* than two that are dissimilar; soft substances more than hard; and tables have been prepared showing the relative tendency of various combinations. One mode of lessening *F.* is by the use of lubricants, such as oil, grease, lard, soap, tar, black-lead, etc. Another is by the use of *friction*, or rather *anti-friction wheels*. This is an arrangement by which the *F.* of an axle is spread over a larger surface, and rendered less intense at the actual point of working. *F.* is not always a defect in machinery; the working of belts, bands, knots, breaks, etc., very much depends on the utilization of *F.*

**Frieze**, the nap on woollen cloth. — A kind of coarse woollen cloth or stuff, with a nap on one side. — In architecture, that portion of the entablature which is between the architrave and the cornice.

**Friezing**, the forming of the nap of woollen cloth into a number of little hard bars or prominences.

**Frigard** [Fr.], a pickled herring.

Fig 210. — FRIGATE.

**Frigate**, a fast-sailing ship of war (Fig. 210), carrying from 36 to 60 guns.

**Frigeratory**, a chamber maintained at a low temperature for the preservation of meat or vegetables.

**Frill**, a ruff or edging round the neck, sleeves, etc., of a lady's dress.

**Fringe**, an ornamental bordering or edging; trimming for articles of dress and drapery; as, to bed-furniture, window-curtains, table-covers; made of various material, silk, worsted, gold, etc.

**Frippery** [Fr. *frippe*], old garments or furniture; trade in old clothes.

**Frisado** [Sp.], silk plush or shag.

**Frisket**, the iron frame of a printing-press, which keeps the sheet on the tympan.

**Frit**, in glass-making, the calcined materials; an imperfectly fused mass of silica, etc., having to be re-melted.

**Frizettes**, curls of hair or silk.

**Frizons**, a name for silk-waste in France.

**Frizzing**, in leather-manufacture, a process which consists in rubbing *chamois* and *wash* leather with pumice-stone or a blunt knife, after the skins have been *fleshed* and *raised*, till an even thickness is obtained throughout. — Also a peculiar finish

given to the nap of woollen cloth, by forming it into a number of little prominences or tufts.

**Frizzle** [Scotch], the hammer of a gun or pistol; the fire-steel for a tinder-box.

**Frock**, a child's gown; a monk's dress; a gentleman's surtout or square-tailed long walking-coat.

**Frog**, an oblong button for coats or overcoats, swelling in the middle and tapering on both ends, covered with netted thread, and fastening into a loop instead of a button-hole. — A grooved piece of iron placed at the junction of the rails of a railroad where one track crosses another. When placed at a regular intersection of tracks, it is called *cross-frog*. — A loop or other ornament for a sword-hilt.

**Fromage**, the French name for cheese.

**Froment**, the French name for wheat.

**Front**, a set of false hair or curls for a lady. — The dicky for a shirt.

**Frontignan**, a luscious, fine, spirituous, and sweet muscadine white wine, made in the French department of Hérault. The Frontignan vine was almost destroyed by the oidium, and the genuine wine is now very scarce.

**Frontispiece**, the illustration of a book which faces the title-page. — In architecture, the principal face of a building.

**Frontlet**, a bandage for the forehead.

**Frosted**, the dead or lustreless appearance of unpolished gold, silver, or glass.

**Frow**, **Frower**, a cleaving tool, used by coopers for riving staves, etc.

**Frowy-Stuff**, a builder's name for short, or brittle and soft, timber.

**Fruit** [Fr. *fruit*; Ger. *Obst*, *Früchte*; It. *frutta*; Sp. *fruta*]. In familiar language this term is applied to any product of a plant containing the seed, more especially those that are eatable. Among botanists, however, and also in commerce, a *F.* is the mature ovary or pistil containing the ripened ovules or seeds, that is to say, the seed or seeds with the pericarp, as in i, Fig. 211. When divested of the walls or pericarp, a *F.* becomes, commercially, either seed or nut. Currants, strawberries, cranberries, and other kinds of berries are called *small F.* The term *dried F.* applies in commerce to such *F.* as raisins, currants, and figs dried (in the air or in sunshine) in the country of their growth, and packed for exportation. Each fruit being given in this work under its specific name, *F.* is considered here only collectively, as an extensive article of diet and general commerce. — The acidulous and subacid *F.* are antiseptic, aperient, diuretic, and refrigerant. They afford little nourishment, and are apt to promote diarrhoea and flatulency. The saccharine *F.*, or those abounding in sugar, are nutritious and laxative, but are apt to ferment and disagree with delicate stomachs when eaten in excess. Stone-fruits are more difficult of digestion than the other varieties, and are very apt to disorder the stomach and bowels. As a rule, *F.* should never be eaten in large quantities at a time, and only when quite ripe. It then appears to be exceedingly wholesome, and to be a suitable corrective to the grossness of animal food. It also exercises a powerful action on the skin, and is a specific for scurvy in its early stages. Many cutaneous diseases may likewise be removed by the daily use of a moderate quantity of *F.* or other fresh vegetable food. Cases are not uncommon which, after resisting every variety of ordinary medical treatment, yield to a mixed *F.* or vegetable diet. *F.* should be gathered in dry weather, and preferably about noon, because the dew and moisture deposited on them during the night and

earlier part of the morning has then evaporated. They should be quite ripe when gathered, but the sooner they are removed from the tree after this point is arrived at, the better. Immature *F.* never keeps so well as that which has ripened on the tree; and over-ripe *F.* is liable to be bruised and to lose flavor. The less *F.* is handled in gathering the better. Some of them, as *peaches*, *nectarines*, *grapes*, *plums*, etc., require to be treated with great delicacy, to avoid bruising them or rubbing off

FIG. 211. — PEACH TREE AND FRUIT.

the bloom. Some *F.*, as a few varieties of *apples*, *pears*, and *oranges*, etc., are gathered before they are fully ripe, in order that they may the better undergo the perils of transit and storage.

In the statement of the Chief of the Bureau of statistics on the commerce of the U. States for the year 1878, our imports of *F.* for that year are valued at \$9,738,546; but it must be observed that in this large figure are included the nuts (almonds, walnuts, filberts, etc.) which certainly enter for a large part in the total. Our exports of *F.* during the same year were as follows:—

Apples (green or ripe).....	\$386,261
(dried).....	290,085
Other fruits (green, ripe, or dried).....	296,310
Fruit preserved in cans or otherwise.....	435,450
Total.....	\$1,378,106

*Imp. duty:* green, ripe, or dried fruit, 10 per cent. Preserved in their own juice, or put up with water only in hermetically sealed cans, jars, or bottles, 25 per cent. Preserved in sugar, 35 per cent.

**Fruit-Essences** are sweet flavoring substances obtained from various kinds of *F.*, but most generally prepared artificially from amylic, butyric, pelargonic, valerianic, and other ethers mixed in alcohol, and colored to represent the juice of the *F.* from which they are supposed to be derived. By judicious mixtures, the flavor of almost any fruit can be more or less perfectly imitated. They are used by confectioners, and largely manufactured at Wolverhampton, England, and at Philadelphia.

**Fruit-Jar**, a jar for preserving fruit, usually made of glass, and sometimes of earthenware.

**Fruit-Knife**, a dessert-knife for cutting fruit. The blade is usually made of silver (or plated), which is not perceptibly acted upon by the acids of the fruit.

**Fruit-Picker**, an implement for reaching up to and picking fruit from a tree.

**Fru mentaceous**, pertaining to wheat or other grain.

**Fru mentazzo**, a name in the Mediterranean ports for damaged grain unfit for human food.

**Fru ndele**, a dry measure of two pecks.

**Frying-Pan**, a flat open iron cooking vessel with a handle, for frying meat, etc., over a fire.

**Fuang**, a small Siamese money, the half of a salung, equal to about 8 cents.

**Fuchsine**. See ANILINE (RED).

**Fucus**, a name for many kinds of seaweed, some of which are eaten raw as food by man and beast; while others afford soda, iodine, and glue.

**Fuel**, any substance used for making a fire to obtain heat, as wood, coal, coke, charcoal, lignite, turf, etc. Many kinds of so-called *artificial fuel* are in use, made of various mixtures, in which coal-dust, coke-dust, sawdust, peat, asphaltum, bitumen, pitch, and other ingredients are employed. They are not very extensively used, except as substitutes for steam-coal on board ship, wherein peculiar qualities are needed. The cost of fuel being a direct element in estimating the relative efficiency of steam-power compared with other sources of power, engineers are directing attention to the capabilities of different kinds of fuel, measured by the quantity of water which the heat from a given weight of fuel will evaporate.

**Fulcrum-Forceps**, a dentist's instrument, in which one beak is furnished with a hinged plate which bears against one side of the object, while the other beak has the usual tooth or gouge shape. — *E. H. Knight.*

**Full-Bound**, a book bound with leather.

**Fuller**, a scourer and cleanser of woollen cloths.

— A half-round set hammer, used by blacksmiths for widening out a piece of iron, and condensing the particles thereof.

**Fuller's-Earth** [*Fr. terre à foulon*; *Ger. Walkererde*; *It. terra da purgatori*; *Sp. tierra de batan*], a species of clay, of a greenish white, greenish gray, olive and olive green, and sometimes spotted color. It is usually opaque, very soft, and feels greasy. It is used by fullers to take grease out of cloth before they apply the soap. The best is found in Buckinghamshire and Surrey, England. When good, it has a greenish white or greenish gray color, falls into powder in water, appears to melt on the tongue like butter, communicates a milky hue to water, and deposits very little sand when mixed with boiling water. The remarkable detergent property on woollen cloth depends on the alumina, which should be at least one fifth of the whole, but not much more than one fourth, lest it become too tenacious. In recent times other substances have frequently been substituted.

**Fulling**, a process whose invention is lost in antiquity (Fig. 212), by which cloths, stuffs, and stockings are cleansed, scoured, and pressed, to render them stronger, closer, and firmer.

The asperities upon the surface of wool render the spinning of it and the making it into cloth difficult operations. In order to spin wool, and afterward convert it into cloth, its fibres must be covered with a coating of oil, which, filling the cavities, renders the asperities less sensible; in the same way that oil rubbed on the surface of a very fine file renders it less rough. When the piece of cloth is finished, it is carried to the *fulling-mill*, where it is beaten with heavy stampers in a trough full of water in which some fuller's-earth has been mixed, for the purpose of cleansing it from the oil. The clay combines with the oil, which it separates from the cloth, and both are washed away together by the fresh water which is brought to it by the machine. But the scouring of the cloth is not the only object in view in fulling it. The alternate pressure given

by the stampers to the piece of cloth occasions (especially when the scouring is pretty far advanced), an effect analogous to that which is produced upon felt by the hands of the latter. The fibres of wool which compose one of the threads, whether of the warp or the woof, assume a progressive movement, introduce themselves among those of the threads nearest to them, then into those which follow; and thus, by degrees, all the threads, both of the warp and the woof, become felted together

Fig 212. — FELLING IN ANCIENT EGYPT  
(From a tomb at Bent Hassan)

The cloth, after having by this means become shortened in all its dimensions, partakes both of the nature of cloth and of that of felt, and may be cut without being subject to ravel. Lastly, the cloth has acquired a greater degree of thickness, and forms a warmer clothing. Kuit worsted also may thus be rendered less apt to run in case a stitch happen to drop. — The felling-machine is being gradually superseded by the *felling-machine*, in which rollers perform the operation more quickly and economically than the stocks.

**Fulminating Compounds** are many in kind, all possessing extremely violent explosive power. Some of them are given under the names of the metals, they being usually metallic salts, more or less complex in character. Among the most powerful and dangerous are the chloride and iodide of nitrogen, the fulminate of silver, and the fulminate of mercury, which is largely used for priming percussion caps. See PERCUSSION-CAP.

**Fulwa**, a solid oil of vegetable butter obtained in India from *Bassia butyrosa*.

**Fumler**, a French word for dung, or manure.

**Fumigation** is the employment of vapors of gases extemporaneously extricated for the purpose of destroying contagious or noxious miasmata or effluvia, or to mark unpleasant odors, or to produce a medical action on those parts of the body with which they are brought in contact.

**Fuming-Box**, in photography, a tight box in which the sensitive paper, after receiving the chloride and nitrate of silver, and before its exposure to light under the negative, is exposed to the fumes of ammonia for having greater depth and brilliancy in the resulting print.

**Function**, an employment; a duty.

**Functionary**, one who holds a public office.

**Fund**, a stock or capital. — Money or income destined to the payment of the interest of a public debt, or for the support of some permanent object. — (Used in the plural.) Money lent to a government, constituting the stock of a national debt, for which interest is paid; as, the *funds* have fallen. See NATIONAL DEBT.

**Fund-Holder**, an owner of government stock or public securities; one who has property in the funds.

**Funded Debt**, a permanent loan on which an annual interest is paid.

**Fünen**. See DENMARK.

**Fundy (Bay of)**, an inlet of the Atlantic, sets up between Cape Sable, the S. point of Nova Scotia, and Mount Desert Island, in Maine, a distance of 150 m. The bay is divided, in its S. E. part, into two branches, the N. called Chignecto Bay, the head of which is 170 m. from Eastport. The S. E. part is called the Basin of Mines, 150 m. from Eastport. Passamaquoddy Bay opens into it on the N. W., near its mouth. Gypsum is ob-

tained on the Basin of Mines, and grindstones on Chignecto Bay. This bay is very peculiar; its shores, on both sides, are rocky and abrupt, while near its head the tide, pressed and confined within diminished limits, rushes with much violence over extensive and wide-spread mud-flats, and rises generally 60 feet or more. Its fisheries are valuable and extensive.

**Funeral**, an interment; a common name for the carriages or procession attending the burial.

**Funeral Plume**, an elaborately prepared and expensive set of sprays of ostrich feathers mounted on wires for fixing on horses' heads, harnesses, or coffin-lid boards.

**Funifera Cordage**. See PIASSARA.

**Funnel**, a hollow conical vessel, usually of glass, tin, or earthenware, with a pipe at the apex, for pouring liquids into small-mouthed vessels (see FILTRATION). — The sheet-iron chimney of a steamer, carried to a sufficient height to assist the draught of the furnace.

**Funt**, the Russian pound weight of 14 oz.  $7\frac{1}{2}$  drachms.

**Fur**, the fine soft short hair on the skin of certain animals inhabiting the colder climates, which is worn for warmth or ornament. In fur-bearing animals the fur lies alongside of another covering, called the *over-hair*. The fur differs from the over-hair in that it is soft, silky, curly, downy, and curled lengthwise, while the over-hair is straight, smooth, and comparatively rigid. These properties of fur constitute its essential value for felting purposes, and mark its difference from wool and silk, the first, after some slight preparation by the aid of hot water, readily unites its fibres into a strong and compact mass; the others can be best managed for spinning and weaving. On the living animal the over-hair keeps the fur filaments apart, prevents their tendency to felt, and protects them from injury, thus securing to the animal an immunity from cold and storm; while, as a matter of fact, this very over-hair, though of an humbler name, is most generally the beauty and pride of the pelt, and marks its chief value with the furrier. We arrive thus at two distinct and opposite uses and values of fur. Regarded as useful for felt, it is denominated *staple fur*, while with respect to its use with and on the pelt it is called *fancy fur*. For the one purpose the Russian hare skin is more valuable than the Russian sable, while for the other the sable may be valued at one thousand times the former. — The history of fur can be read in Marco Polo, as he grows eloquent with the description of the rich skins of the khan of Tartary; in the early fathers of the church, who lament their introduction into Rome and Byzantium as an evidence of barbaric and debasing luxury; in the political history of Russia, stretching out a powerful arm over Siberia to secure her rich treasures; in the history of the French occupation of Canada, and the ascent of the St. Lawrence to its source in Lake Superior, and the subsequent contest to retain possession against England; in the early settlements of New England, New York, and Virginia; in Irving's "Astoria," in the records of the Hudson's Bay Company; and in the annals of the fairs held at Nijni-Novgorod and Lepsic. Here it may suffice to give some account of the present condition of the trade in fancy fur. The collection of skins is now chiefly a matter of private enterprise. Few, if any, monopolies exist. The Alaska Commercial Company, now about twelve years old, enjoys some special privilege for the taking of seal-skins on the Pribiloff Islands, and some peculiar restrictions exist in Russia in relation to certain peltries,

but beyond this, the trade in furs is a free one the world over. Individual enterprise, skill, forecast, and capital have an open field. The Hudson's Bay Company, with its chief office in London, still maintains its organization, but conducts its affairs in North America under no special or royal grant, and competes in the open market with individual traders throughout Canada, Labrador, Manitoba, and Columbia. Its collection of peltries is offered to the highest bidder at public auction in London, in January, March, and September of each year. Private collectors and dealers throughout Canada and the U. States forward their furs to the seaboard, chiefly to New York, for sale there, or for consignment principally to London and to Leipsic. The latter town still maintains the custom of spring and autumn fairs, at which most kinds of wares are sold or exchanged with dealers from Turkey, Austria, and Russia. Nijni-Novgorod is the chief fair for European Russia, though very important fairs are also held in Kasan and in Irbit among the Ural Mountains. The most important fair for Eastern Siberia is held at Kiachta, on the borders of China, where an extensive exchange of furs is carried on with the Celestials. Japan has added but little to the activity or extension of the fur-trade, though her northern shores have furnished many a fine fur seal and sea-otter to the hardy navigator. Staple furs, or those used chiefly in the manufacture of hats, are those of the hare and the rabbit, collected mainly in Russia, Germany, France, and England, dressed, carotred, and cut from the skin in Western Germany, France, Belgium, and England, and thence distributed to the manufacturing centres of the world; and here it may be added that the clippings and cuttings of fancy furs from the workshops of furriers are all saved, and find their way to the machinery, which utilizes the waste, and transforms them into hat-makers' furs. But of all these fur marts, that of London is the chief, for thither tend, by the laws of trade, not only much of the produce of Asia and Europe, but also the fine peltries of Chili and Peru, the nutria from Buenos Ayres, the fur seal of Cape Horn and South Shetland, the hair seal from Newfoundland, as well as the inferior peltries of Africa. To prepare fur skins in a way to endure this long transportation is a simple and easy matter. When stripped from the animal the flesh and fat are carefully removed, and the pelts hung in a cool place to dry and harden; nothing is added to protect them. Care is taken that they do not heat after packing, and that they are occasionally beaten to destroy worms. A marked exception is the case of the fur seal, which is best preserved by liberal salting and packing in hogsheds. All other raw furs are marketed in bales. — *Kinds and Quantities.* Few kinds of animals furnish a pelt of suitable weight and pliability, and all of them differ widely in elegance of texture, delicacy of shade, and fineness of over-hair, and it is these differences which determine their place in the catalogue of merchandise. These few animals are not very prolific, and many of them attain their greatest beauty in wild and uncultivated regions. To this remark there are some notable exceptions. Being thus few in kind, and limited in quantity, one might fear the extinction of the several choice varieties through the persistent energy of the trapper. But here the fickleness of fashion steps in, and does for the fur-trade what the law of supply and demand does for the more staple articles of commerce. Fashion, fastidious and fickle, neglects the use of certain kinds for a season; the market price of the pelt no longer repays the outfit of the

trapper; the hunt is intermitted, and in two or three years the animal regains its numbers and strength. The annual collection of furs is thus a matter of ceaseless change; but the following may be relied on as an estimate correct enough for all practical purposes: —

*Average Annual Collection.*

Badger .....	America .....	5,000

We give here a brief account of the qualities of the pelts, with some general remarks as to their average value and their customary uses.

*Badger.* — Size, 2 by 3 feet; overhair coarse, 3 to 4 inches long, black with silver spots. The German are the best. Fur woolly. American have softer overhair. Used for robes, military trappings, and brushes. Value of prime, from 50 cents to \$1.50 per skin.

*Bear, Black.* — Size 3 by 6 feet; overhair 6 to 8 inches long, fine, flowing, and glossy; fur thin. Best are American. Used for robes, military caps, and mats. The finest are the cubs. Value of prime, from \$5 to \$20.

*Bear, Brown.* — Same size as the black, and very fine in overhair. Found only in the Hudson's Bay territory. Used for muffs and garniture. Value of best prime, \$75. Quantity very small.

*Bear, Grizzly.* — Larger than the black; coarse hair; thick heavy pelt. Only found in western part of the U. States. Used as robes. Value \$5 to \$10.

*Bear, White.* — Largest of the bear family; hair short and rigid; pelt thick. Found only in the Arctic regions. The best pure white are used for robes. Value from \$50 to \$100.

*Beaver.* — Size 2 by 3 feet; overhair 3 inches long, coarse and brown in color; fur thick, fine, and dark gray. Best are from Labrador and Moon Fort. Used in every form and fashion in all northern countries; highly prized in Russia and China. Value from \$1 to \$3 per pound in the raw parchment state.

*Buffalo.* — Size, 8 to 12 feet long; hair coarse, color dun brown. Only found on the western and northern American prairies. Best are from the region of the Saskatchewan River. Prime are used as robes; coarse and unprime as leather for moccasins. Value \$3 to \$10.

*Chinchilla*. — Two kinds, real and bastard. Size of real 8 by 12 inches; overhair and fur of equal length, — about 1½ inches long, very fine, and like wool may be spun and woven color silver-gray and dark. Best are from Peru. Used for muffls, boas, and borders on garments. Value from \$1 to \$3. The bastard are from Chili (chinchilla means the Chilian skin), short in fur, small in size, weak in pelt, and are worth from 10 to 20 cents.

*Cat, Wild*. — Overhair and fur thin and coarse; color gray; value and uses very limited. Civet cats are sometimes admired for their singular marks, but are in poor demand. House cats are too well known to require a description. Their colors are black, gray, red, and mottled. Best come from Holland, the poorest from Russia. Used very generally for fur-work. Price of best black \$1 to \$2; other sorts nominal.

*Ermine*. — Size 4 by 10 inches, overhair and fur fine, soft, and close, pelt thin and tough; color pure white, the tip of the tail black. Best are from Barabinsk and Ichiun, in Siberia. Used for muffls, garments, and linings. Value variable; the best have been as high as \$1.50, and as low as 15 cents.

*Fisher*. — Size, 15 by 30 inches; overhair very fine, glossy, dark, and durable, 2 inches long; fur close, tail 12 inches long, bushy, and dark. A right noble skin. Best from British America. Value from \$10 to \$20.

*Fitch*. — Size about that of the American mink; overhair fine, 1½ inches long, with dark points; fur a golden yellow. Best from Germany, Holland, and Denmark. Smallest from Russia. Used for ladies' furs according to the prevalent fashion. Value from 50 cents to \$1.50.

*Fox, Silver*. — Size, 2 by 4 feet; overhair thick and fine, 3 inches long, varied in color from pale silver to a brilliant blue black; fur fine and curly; its beauty places it at the head of all fancy furs, the tail is a royal bush. The choicest are from Labrador and Moon Fort; those of Russia are more woolly and less valuable. Used for muffls, boas, and linings of robes. Price from \$50 to \$200.

*Fox, Cross*. — Not quite so large as the silver, with fine overhair, but a shade of red at the points, and from the paleness of the fur making a distinct dark cross at the shoulders. Best are from the Hudson's Bay Territory, and valued from \$10 to \$40.

*Fox, Blue*. — Size the same as the cross, with gray-blue overhair, and a woolly fur. The finest are from Archangel on the White Sea, and from Greenland. Value from \$10 to \$20.

*Fox, White*. — Size the same as the cross, with pure white overhair and fur. The best are from Labrador, the poorest from Asia. Value from \$1 to \$3.

*Fox, Red*. — Well known to all northern nations; abundant in Europe, but in size and beauty inferior to the American family. The former fetch \$1, while those from Labrador are valued at \$4.

*Fox, Gray*. — Only found in the U. States. Overhair is gray, sprinkled with silver on the back, the sides are yellow, and the tail an ashen gray. — Value from \$1 to \$2.

*Fox, Kitt*. — Found in northwest America and in Tartary. Overhair fine, the back is a pure gray, the sides yellow, and the belly white. In size it is the smallest of the faxes. Price from 25 to 75 cents.

*Hatterer*. — Size, 3 by 5 inches; hair short and close, back gray and the sides yellow. A great trouble to the farmers in Germany, who spare no pains to exterminate them. The pelt is made into linings for cloaks.

*Hare*. — Overhair fine, fur very long, fine, abundant, and strong; pelt weak; color gray and white. Best are from Russia. This skin is largely used by furriers, but its fur is among the best for hatters' purposes. Value from 10 to 25 cents.

*Kediak*. — Found only in Asia, and attains the size of the American mink, overhair a golden red, 1½ inches long. The tails make excellent pencils for painters. Value from 50 cents to \$1.

*Lamb*. — The finest, dark, close-curling skins come from Persia; the next grade from the Crimea, and are gray in color; inferior skins from Astrakhan. All these are used by furriers for caps, borders, and garments. The finest Persian are worth \$3 to \$5, the Crimean \$1.50, and the Astrakhan from 25 to 50 cents. The lamb-skins of western Europe are used for lining gloves. Angora sheep are sometimes in demand, and are colored red, blue, gray, and orange to suit the fashion for fringes and borders. Their value is from \$3 to \$10.

*Leopard*. — The finest from Asia. Specimens are rare, and price variable.

*Lynx*. — Size, 2 by 3½ feet, overhair fine and flowing, of a clear silver-blue shade, sprinkled with black; length of overhair 3 to 4 inches. Best are from Sweden and Labrador. Value from \$2 to \$5.

*Marten, American*. — Size from 5 to 15 inches to 8 by 20 inches; overhair fine and flowing, 1 to 2 inches long; fur close and thick; color of best a dark coffee brown, of poorest a pale yellow. The finest are from the Great Whale River and Labrador. Always a choice and valued pelt. Price of best

\$25, of poorest 50 cents. The tips of the tails are highly prized for artists' brushes.

*Marten, Stone*. — Found in Europe; the best from Hungary and Turkey. Color a dull gray, overhair coarse, and fur woolly. Value of best prime, \$2 to \$3.

*Marten, Beaver*. — Found in Europe and Asia, of fine overhair, but woolly fur, of a brownish color, approaching that of the American marten, and furnished with a long and bushy tail. Value from \$5 to \$10.

*Marten, Russian Sable*. — These skins are in the highest estimation with furriers. Size about the same as the American marten, but the overhair is much more fine and flowing, of a rich bluish dark shade, and from 1½ to 2½ inches long, the pelt is very soft, tough, and durable. The best are from Yakutsk in Siberia, the next from the Lena River, and the poorest from the Lower Amoor. Very choice grades, but of a browner shade, are furnished by Kametchatka. Value of the poor Saghalien from \$1 to \$2; while the darkest from Okhotsk will command \$1.50.

*Mink, American*. — This valuable skin has nearly the size of the marten, with an overhair that is shorter and slightly more rigid, but vies with the marten in elegance of lustre, the choicest having a dark blue shade that is always admired in furs. The best are from Nova Scotia, the State of Maine, and the Labrador coast. It is most abundant in the middle and north-western States. Value of the best, from \$3 to \$10.

*Mink, Russian*. — Of smaller size than the American, and inferior in all other respects, but still a valuable pelt. Price of prime, from 50 cents to \$1.50.

*Monkey*. — From the west coast of Africa, has a long, thin, flowing hair; of various colors, chiefly black and dun gray. Has a limited use with furriers, fetching from 50 cents to \$1.50.

*Musk-Rat*. — A well-known fur in the U. States. Size 8 by 12 inches; overhair coarse and light brown; fur fine, thick, and silky; in general favor with furriers, and available for a great variety of purposes. Best are from New England and New York; very prolific in cultivated regions. The price is very fluctuating, and as the annual collection varies from three to

Fig. 213. — Fox.

five millions of skins, it is difficult to forecast the market value. Price for prime, from 12 to 75 cents. A variety of black-colored musk-rat from Delaware and Maryland fetches double these prices.

*Nutria*. — From the La Plata, South America; in size and value between the beaver and the musk-rat, overhair coarse and rigid; fur short and fine; pelts too often unsound, and hence the value of the fur is chiefly for hats. Price of dry skins from 25 to 50 cents per pound.

*Opussum*. — Chiefly from the U. States, but some also from Australia. Overhair long, coarse, and whitish gray, fur woolly. Best from Ohio. Value from 10 to 50 cents.

*Otter*. — Comes from all northern countries. Size of best, 2 by 5 feet; overhair thick and close; color brown black. Best are from Labrador and Canada. The skin is in high reputation and general use with furriers. Value of best, \$7.50 to \$15.

*Otter, Sea*. — Found only in the North Pacific Ocean, on the coasts of Alaska, Kametchatka, and Japan. Size, 2 by 6 feet, overhair exceedingly fine, and extending but little beyond the fur, which itself is very thick, close, fine, and silky, color dark brown, occasionally with silver points regularly interspersed; pelt pliable and firm. The poorest skins are not more valuable than those of the beaver, but the fine choice specimens command from \$100 to \$500. They are in high repute with the Russians and Chinese.

*Rabbit*. — Size, 10 by 16 inches; fur thick and fine; pelt weak; color all shades from black to white. Best are found in England, but the purest come from Poland. The best colored skins are used by furriers, but much the larger portion is cut for hatters' fur. The animal is largely bred in warrens, and its flesh used as food; the pelts thus become of secondary importance, and, being abundant, supply a cheap fur.

**Raccoon.** — One of the peculiar and valuable pelts of the U. States, and flourishing best in cultivated regions. Size, 1 by 2 feet; overhair not fine, but bright in color, 3 inches long, thick, and flowing; fur resembling that of the beaver; color from silver blue to gray brown and coffee brown. Best are from Michigan and Ohio. Average value of prime, \$1. Some specimens vie with the fisher in its peculiar shade, and some even with the silver fox, and such rare skins bring from \$5 to \$20.

**Seal, Hair.** — Chiefly from the North Atlantic. Size from 3 to 10 feet; hair coarse and rigid; no fur; divided into white coats, blue-blacks, mottled, and ordinary. Used for saddlery and military purposes. Average price, 50 cents.

**Seal, Fur.** — Found only in the Pacific and in the South Atlantic. Size of the wigs, 4 by 8 feet; of the large, 3 by 6 feet; middling, 2½ by 5 feet; small, 2 by 4 feet; the pups vary in length from 2 to 4 feet. Overhair coarse and rigid; fur fine, thick, silky, and very uniformly distributed. Pelt thin, pliable, and of light weight. The largest number come from Alaska, whence 100,000 are allowed by law to be brought annually. The best of these are the prime middling pups. Value varies from \$5 to \$15 in the salted state. A few fine skins come from the coast of British Columbia, and being caught in winter are in prime condition. The choicest skins are taken on the South Shetland and South Georgia Islands in the Antarctic Ocean. Fur fine beyond comparison; pelt very pliable, light and thin and firm. Value, salted, from \$10 to \$50.

**Skunk.** — Another peculiar production of the U. States. Size, 10 by 16 inches long, overhair fine, 3 inches long, dark blue and coffee brown, thick, glossy, and flowing. Many have two white stripes, more or less broad, extending from the head to the tail. It is now easy to deodorize the skin, and the

Fig. 214. — OTTER.

fur is a popular one in all countries. The best are from New York and Ohio; value of best prime black, from \$1 to \$2.50.

**Squirrel.** — Only those of northern Europe and Asia have a value as merchandise. American are worthless. Size 3 by 6 inches; overhair and fur equally fine; color from pale blue to clear dark blue; best are from Eastern Siberia; palest and poorest from European Russia; bellies white; tails long and bushy. This fur is in universal demand among furriers for muffs and linings, as well as for large garments. Pelt pliable and tough; fur durable, close, and fine. The tails are made into boas and brushes.

**Tiger.** — Specimens are rare. Those from Bengal are large and short in hair, but well marked; while those from Northern China have hair 2 to 3 inches long, and frequently measure 10 to 14 feet in length. Value of the latter, from \$50 to \$100.

**Wolf.** — The largest are from Labrador, measuring from 4 to 6 feet long, chiefly gray-brown in color, with long, flowing, coarse overhair. The finest are from Fort Churchill, and fetch a high price. The American prairie-wolf is a variety inferior in every respect. Price of best, \$10; of the inferior, \$1. The wolf is very destructive of the fur-bearing animals, and is an object of extermination with all trappers.

**Wolverine.** — From Russia, Norway, and Hudson's Bay. Color a clear dark brown, overhair coarse, 2½ inches long. Value from \$3 to \$6.

Of the fur-bearers, those that seek their food in water have their finest but shortest fur on the belly, and longer fur upon the back; while those that avoid the rivers have their longest and finest fur upon the back, and their bellies clothed with fine, long, flowing overhair. — **Dressing.** Raw furs are made ready for use by softening the pelt with pure butter or sweet oil, trampling them in tubs filled with fine hardwood sawdust at about blood-heat, drawing the pelt over a sharp knife to remove every particle of flesh, and finally trampling them again in clean sawdust. The pelt thus becomes soft and pliable, like the fine kid used for gloves.

They are then ready for the furrier, who assort the skins as to color and overhair, and cuts them in various ways to bring them to the pattern of the article required. Having been sewed together with a close, fine overseam, the article is dampened, and stretched upon a smooth pine board after a pattern marked, then nailed along its edges and left to dry. After removal from the board the article is trimmed, and softened by rubbing, and is then ready for the liner. The skill of the furrier lies in the taste exhibited in the arrangement of the furs, and in the economy of use of material. — **Dyeing.** Furs are dyed in a variety of ways to make them uniform in color, and adapt them to the fashion and taste of the time. Ordinarily this is a cheap and ready process, and only becomes an art when employed upon fine skins, from which the overhair has been first removed by plucking, leaving the fur alone to receive the dye-stuff. Among these are the skins of the musk-rat, beaver, otter, and especially the fur seal; the last has received very careful attention, as its entire value depends upon the perfection and success of the process. Unprime fur seals part with their overhair very reluctantly, while the seasoned skins

are very readily unhaired, leaving the fur in all its smoothness; thus the best grades are likely to be very good, while the rest rank only from ordinary to very common. A subsequent process is the removal of all grease from the fur, which is effected by repeated washings in softened water; if this is imperfectly done, the color will be uneven and not permanent. The final work is to prepare a dye of suitable strength, and apply it in a suitable way, to infuse the coloring matters into the fur, without suffering too much of it to reach the pelt, whereby its durability might be ruined. London claims to have accomplished this

for the seal-skin in a manner that distances all competition; and it certainly enjoys a wide popularity, as well as the substantial fruits of the sale of its production of colored seals. But America also has its successful dyers of seals, one of the most important of the results we have achieved being the giving to the fur seal a fine deep brown color, without injuring or burning the fur, while leaving the pelt soft, light, and durable. — **Prices of Fancy Furs.** The market value of dressed and manufactured furs is at the mercy of fickle fashion and the weather. The production of any one variety is very limited, and consequently those that are in fashion during a cold winter command full and even extravagant prices, while others, of equal intrinsic merit, have a merely nominal value. The consumer is not more responsible for this than are the furrier and the fur merchant. It was the remark of an old and successful fur-dealer that "furs when wanted are diamonds, when not wanted are charcoal." This fact renders the trade an extremely hazardous one, and tends to make the venture in it a matter of speculation rather than of provident enterprise; and while the consumer occasionally may have to pay a very extravagant price for some few varieties of furs for a short period, it happens far more frequently that the fur-dealer is a severe sufferer by reason of sanguine anticipations of advance in values, which in nine cases out of ten are doomed to disappointment.

For further information, see the excellent work "Fur and the Fur-trade," by M. M. Backus (Little, Brown, and Co., Publishers, Boston, 1879), from which the foregoing is borrowed.

Our foreign trade in furs for the year 1878 was as follows: Imports of undressed skins (chiefly from England and the Canadas), \$1,714,066; imports of furs and dressed fur skins (mostly from England, France, and Germany), \$2,230,204. Exports of furs and fur skins (mostly to England and Germany) \$2,618,100.

*Imp. duty:* caps, hats, muffs, tippets, and all manuf. of fur, or of which fur shall be a component (including money-plates), 35 per cent. — *Hares' furs*, undressed and not on the skin, 20 per cent. — *Hatters' furs*, not on the skin, and dressed furs on the skin, 20 per cent. — *Fur skins* of all kinds not dressed in any manner, free.

**Furbelow**, a plaited border; the flounce for a dress.

**Furbisher**, a burnisher or polisher.

**Fur Cap**, a seal or other skin cap.

**Fur Coat**, a wrapper for cold weather made of bear-skin, beaver, seal, or other fur.

**Fur-Cutting Machine**, a mechanical contrivance for shaving peltries at the back of the skin, so as to loosen the long hairs, leaving only the fine under-fur.

**Furdingar**, a liquid measure of Finland, about 7½ pints, the fourth part of the tunna.

**Furling**, in naval parlance, the wrapping or rolling a sail up snugly to the yard or boom, and binding or securing it.

**Furlong**, an English measure of length, 40 poles, the eighth part of a mile.

**Furnace**, an apparatus to contain combustible matter, and supplied with air in various ways to facilitate its combustion and produce heat, which is directed upon an object in the vicinity, such as an ore or metal under treatment, a steam-boiler, etc. *F.* are constructed according to many different patterns, with varying degrees of complexity in arrangement, but all may be considered as combining three essential parts, namely, the fire-place in which the fuel is consumed; the heated chamber, laboratory, hearth, or working-bed, as it is variously called, where the heat is applied to the special work for which the *F.* is designed; and the apparatus for producing rapid combustion by the supply of air under pressure to the fire. In the simplest cases the functions of two or more of these parts may be combined into one, as in the smith's forge where the fireplace and heating chamber are united, the iron being placed among the coals, only the air for burning being supplied under pressure from a blowing engine by a second special contrivance, the tuyere, tuyron, twyer, or blast-pipe; but in the more refined modern *F.*, where great economy of fuel is an object, the different functions are distributed over separate and distinct apparatus, the fuel being converted into gas in one, dried in another, and heated in a third, before arriving at the point of combustion in the working-chamber of the *F.* proper. The most obvious distinction that can be used in the classification of *F.* is founded on the method adopted for supplying air, which may either be blown into the fire, under a pressure above that of the atmosphere sufficient to overcome the resistance presented by the packed columns of fuel and other materials to its free passage, or be drawn through it by a partial vacuum in a chimney formed by the heated gases on their way to the atmosphere. The former are known as *blast furnaces*, and the latter as *chimney, draught, air, or wind furnaces*.

**Furnished**, a term applied to anything completed or having the necessary appurtenances; a house which is properly filled with necessary goods, upholstery, cabinet-ware, culinary utensils, and garniture; fit for occupation.

**Furniture Japanner and Polisher**, a workman who oils, varnishes, and prepares for sale new cabinet articles, and cleans and polishes old worn pieces of room furniture.

**Furniture-Polish**, see French Polish.

**Furniture-Printer**, a maker of fabrics for covering articles used in rooms.

**Furniture-Woods**, hard, ornamental woods, used for cabinet-work.

**Furrier**, a dealer in skins; a manufacturer and vender of various articles of fur.

**Furriery**, furs in general; the trade in furs.

**Furring**, fixing thin scantlings on the edges of timber to make the surface even. — *Incrusting a boiler with a scaly deposit.*

**Furrow**, the trench made by a plough. — *The grooves in the face of a millstone.*

**Fur-Trade**. See *FUR*.

**Fur-Waste**, the clippings and refuse of fur manufacturers' shops, which are imported in bales from England and France and used in the manuf. of felting-cloths.

**Fuse**, a case of wood or metal charged with an explosive composition, and having a slow match attached for firing a shell or blast charge.

**Fusee**, the conical part of a watch or clock, round which the chain or cord is wound (see *C* in Fig. 27, and *B* in Fig. 83). — *A lighted or slow match used by smokers for igniting tobacco.*

**Fusee-Engine**, a clock-maker's machine for cutting and shaping fusees.

**Fusel Oil**, a strong-smelling oil, produced along with alcohol during the fermentation of grain, potatoes, etc., on the large scale, and which gives the peculiar and disagreeable flavor and odor to raw whiskey. It is found chiefly in the last portion of the spirit which passes over, called the "faints," to which it imparts its characteristic odor and flavor. By rectifying the faints at a very gentle heat, most of the alcohol and water first pass over together with only a little fusel oil, whilst the latter forms the residuum in the still. It essentially consists of hydrated oxide of amyl, but trifling and variable quantities of other organic compounds are mixed with it, which slightly modify its character, more particularly its odor and flavor. The oil of potato spirit is the purest form of crude fusel oil. The exertions of the distiller are directed as much as possible to lessen the formation of fusel oil during the fermentation of his "worts," and to eliminate, during the distillation and rectification of his liquors, the greatest possible proportion of that with which they may be contaminated. Fusel oil is a nearly colorless volatile liquid, with a rather high boiling-point, a durable, penetrating, offensive smell, and an acrid, burning taste; when swallowed, it occasions nausea, giddiness, headache, etc.; in slightly larger quantities, vomiting, delirium, oppressive respiration, and lessened sensibility to pain; its vapor also produces these effects. In quantity, it is a narcotic poison. The greater intoxicating power of whiskey, more especially that from raw grain, than other spirit is due to the larger quantity of fusel oil which it contains. *Imp. duty* \$2 per gallon.

**Fuse-Setter**, an implement used by miners for driving home wooden fuses.

**Fusible Metal**, an alloy of bismuth, lead, and tin, which melts at a surprisingly low temperature. Different degrees of fusibility are obtained by varying the proportions as follows: 1. Bismuth, 2 parts; lead, 5 parts; tin, 3 parts. Melts in boiling water. 2. Bismuth, 8 parts; lead, 5

parts; tin, 3 parts. Melts below 212° F. 3. Bismuth, 8 parts; tin, 4 parts; lead, 5 parts; antimony, 1 part. The metals should be repeatedly melted and poured into drops, until they are well mixed. 4. Lead, 3 parts; tin, 2 parts; bismuth, 5 parts. Melts at 197° F. 5. To the last, after removing it from the fire, add of quicksilver (warm) 1 part. Liquid at 172°, solid at 140° F. The first four of the above are used to make *toy-spoons*, to surprise children by their melting in hot liquors. A little mercury may be added to lower their melting points. Nos. 2 and 3 are specially adapted for making *electrotype moulds*. The beautiful casts of the French medals known to all electrotypers as *Cliché* moulds are in the alloy No. 3. The above alloys are also used to form *pencils* for writing on asses' skin, or paper prepared by rubbing burnt hartshorn into it, etc.; also as a *metal bath* in the laboratory. The last is used for *anatomical injections*.

**Fusil**, a light musket of an antiquated pattern.

**Fusing-Point**, see **FUSION**.

**Fusion**, a melting; the converting of a solid into a liquid by heat. The liquefaction of ice may be called either fusing or melting. Thus 32° F. may be called the fusing or melting point of ice, the freezing or solidifying point of water. The fusing points of the more refractory substances are only to be ascertained approximately on account of the doubtful accuracy of the indications given by the *pyrometers* at very high temperatures. The pyrometer constructed of platinum is the most delicate, although the rate of its expansion must be uncertain as it approaches its own fusing point. The following are considered to be the fusing points of metals:

Platinum .....	F 3080°	Silver.....	F. 1830°
Wrought iron .....	2910	Zinc .....	700
Steel .....	2500	Lead .....	590
Gold .....	2190	Bismuth .....	500
Cast iron .....	2100	Tin .....	450
Copper .....	1920		

A dull red heat is estimated as 1480°; a bright red heat as 1830°; and a white heat as 2370° to 2910°, F.

**Fusta** [Sp.], a small vessel with lateen sails; a kind of woollen cloth.

**Fustian** [Fr. *futaine*; Ger. *Barchent*; It. *fustagno*; Sp. *fustan*] is a species of coarse, thick tweeled cotton, and is generally dyed of an olive, leaden, or other dark color. Besides the common fustian, which is known by the name of pillow (probably pilaw), the cotton stuffs called *corduroy*, *velverett*, *velveteen*, thick-set used for men's wearing apparel, belong to the same fabric. The commonest kind is merely a tweel of four, or sometimes five leaves, of a very close stout texture, and very narrow, seldom exceeding 17 or 18 inches in breadth. It is cut from the loom in half pieces, or ends, as they are usually termed, about 35 yards long, and after undergoing the subse-

quent operations of dyeing, dressing, and folding, is ready for the market. Of velvet, there are properly only two kinds,—that with a plain, and that with a tweeled, or, as it is here called, a *Genoa ground*, or back. When the material is silk, it is called velvet; when cotton, *velveteen*; and this is the sole difference. In the same way a common tweeled cloth, when composed of silk, is called satin; when of cotton, *fustian* or *jean*; of woollen, *plaiding*, *serge*, or *kerseymere*; and in the linen trade is distinguished by a variety of names according to the quality or fineness, or the place where the article is manufactured.

**Fustic** [Fr. *bois jaune*; Ger. *Gelbbolz*, *Fustic*; It. *legno giallo de Brasilio*; Sp. *palo del Brasil amarillo*], a dye-wood, the produce of a large tree, a species of mulberry (*Morus tinctoria*), a native of tropical America and the West Indies; the best being that of Cuba. It is of a sulphur-color with orange veins, hard and strong, and is imported in the form of logs or large blocks. Its decoction dyes woollens yellow of different shades, according to the "mordant." Alum, tartar, and spirits of tin brighten the tint; acetate and sulphate of iron and common salt darken it; with sulphate of iron it gives olives and browns; with the indigo vat and sulphate of indigo, green. These colors are very permanent. Its yellow turns on the lemon when pale, and on the orange when darker. 1 lb. of old fustic will dye 3 to 5 lbs. of wool. *Zante*, or *young fustic*, is really a species of sumach (*Rhus colinus*), and is quite distinct from the *Morus tinctoria*, or *old fustic*; the latter being a large American tree, while the former is a small European shrub. It grows in Italy and the South of France, but is principally exported from the Ionian Islands and Patras in the Morea. It gives a yellow, turning on the green, but its colors are not very permanent. It is chiefly used in combination with other dyestuffs. It is conveniently stowed among a cargo of dry-goods, as it may be cut into pieces of any length without injury. Only a small quantity of this species of sumach is imported. Its price fluctuates considerably. *Imp.* (in stocks) free.

**Fut**, the French name for a cask, a vessel for liquids; a stock for a gun, or tool; a bookbinder's plough.

**Futaille** (Fr), a cask of any kind for wine, water, or provisions.

**Futainier** (Fr.), a fustian-weaver.

**Futfaill**, **Futfell**, a name in Scotland for the dressed skins of a slink lamb, or one prematurely dropped.

**Futtocks**, in a ship, the timbers raised over the keel, or the encompassing timbers which form her breadth and capacity. *Futtock plates* are iron plates crossing the sides of the top-rim perpendicularly. The dead-eyes of the topmast rigging are fitted to their upper ends, and the futtock shrouds to their lower ends.

**Fyke**, a bow-net for catching fish.

## G

**Gab**, the hook on the end of an eccentric rod, opposite the strap.

**Gabarage**, coarse packing-cloth; a term formerly used for the wrappers in which Irish goods were packed.

**Gabardine**, a coarse smock-frock, or blouse.

**Gabare**, a French lighter; a fishing-boat; a kind of net.

**Gabbart**, a name in Scotland for a canal barge or lighter.

**Gabelle**, a tax formerly levied upon salt and other provisions.

**Gabilla**, a finger or parcel of tobacco in Cuba, consisting of about 30 or 40 leaves. The bales are usually made up of 80 hands, each of four gabillas.

**Gad**, a small iron punch, with a wooden handle, used by miners to break up ore. — A jumper; a boring-bar. — In Scotland, a fishing-rod; a bar of metal.

**Gadesden-Pan**, an evaporating sugar-pan, named after the inventor.

**Gaeta**. See ITALY.

**Gaff**, a spar to which the head of a fore-and-aft sail is bent. — In Scotland, a sort of net.

**Gaff-Topsail**, a light sail set over a gaff.

**Gage**, a pawn or pledge. — A token. — The depth of water displaced by a ship; also the position of a ship in relation to the wind with another vessel, as weather-gage, lee-gage. — The width of a railroad track (see RAILROAD GAGE). — Fine mortar with an addition of plaster of Paris for a finishing coat. — Any instrument used to measure. (See GAUGE.)

**Gage-Cock**, one of two or more stopcocks which are screwed into the boiler of a steam-engine, one above the level at which water ought to stand in the boiler and the other below it. The ejection of steam and water respectively from the cocks indicates the water-level in the boiler to be between the two gage-cocks. Steam from both shows the water to be too low. Water from both shows the water to be too high. — *E. H. Knight*.

**Gagger**, a lifter used by the founder, consisting of a light T-shaped piece of iron.

**Gag-Rein**, in saddlery, a rein which, passing over runners attached to the throat-latch, draws the bit up into the corners of the horse's mouth when pulled upon.

**Gain**, profit; overplus in a computation. — A mortise. — A bevelled shoulder of a binding-joint to strengthen the tenon.

**Gainings**, the acquisitions made by successful trade.

**Gainier** [Fr.], a maker of sheaths or cases.

**Gaiter**, a covering of cloth or leather for the lower portion of the leg and ankle, fitting closely to the shoe; also a sort of high shoe covering the ankle-joint.

**Gala**, a great entertainment. — A Scotch cotton fabric.

**Galactin**, a nutritious milky substance obtained from the sap of the *galactodendron*, the milk or cow tree of South America.

**Galactometer**, **Lactometer**, an aerometer or glass instrument (Fig. 215), for testing the density of milk, consisting of a stem, enclosing scales; of a cylinder serving to float it, and of a bulb charged with shot, serving as a ballast, so that the instrument floats upright in the milk. It is centesimally graduated.

**Galam-Butter**, a reddish-white solid oil obtained in India and Africa from the *Bassia butyracea*.

**Galangal**, a commercial name for the rootstocks of the *Alpinia galanga*, and *A. racemosa*, which have the same properties as ginger. The roots are imported from China, Sumatra, and Java. *Imp. free*.

**Galatz**. See ROMANIA.

**Galbanum**, a gum-resin derived from an uncultivated umbelliferous plant. It is brought from Turkey and the East Indies in irregular tears about the size of a pea, usually agglutinated into masses; of a greenish-yellow color, translucent, having a strong disagreeable odor, and an acrid bitter taste. Its properties are similar to the other fetid antispasmodic gum-resins. It ranks between assafoetida and ammoniacum.

**Galena**, **Lead-Glance**, **Blue-Lead** [Fr. *plomb sulfuré*; Ger. *Bleiglantz*], a native sulphuret of lead, which usually occurs in heavy, shining, black, or bluish lead-colored cubical masses. It is the richest ore of lead, and nearly all the lead of commerce is obtained from it. It is used in the form of powder, called *alquifoux*, for glazing pottery. Immense deposits of it exist in Missouri, Illinois, Iowa, and Wisconsin, especially near *Galena*, a thriving city of Illinois, which owes its prosperity to its rich mines of lead.

**Galiot**, **Galliot**, a light galley, a Dutch ship.

**Galipot**, white-pine resin; the residue of the turpentine which has lost its volatile oil by spontaneous evaporation; when purified, it is called Burgundy pitch.

**Gall**, the bitter fluid secreted by the liver; ox-gall is used for scouring cloth; and when refined, by artists to fix chalk and pencil drawings before tinting them. See GALLS.

**Galleon**, a large four-decked vessel formerly used by the Spaniards in trading to South America.

**Gallery**, in mining, an underground excavation, vertical or horizontal. — A long narrow room in the wing of a building. — The upper places or seats in a church or theatre. — A raised balcony or walk in a room. — A railed projection at the stern or quarter of a ship.

**Galley**, a printer's long frame with a ledge (Fig. 216), on which the compositor empties the contents of his stick as often as it is filled, so that the com-

Fig. 215. — GALACTOMETER.

Fig. 216. — COMMON GALLEY.

posed lines, or arranged letters, may be made up into columns or pages; there are newspaper, book, and job galleys. — The place set apart for the fire-hearth and the use of the cook in a ship. — A long sharp boat for a ship's use, carrying from 10 to 12 oars.

**Gallic Acid**, a peculiar acid obtained from gall-nuts, divi-divi, and other vegetable substances,

rich in tannin. It forms small, feathery, and nearly colorless crystals, which have a beautiful silky lustre; that of commerce is usually of a pale yellow color; it is soluble in 100 parts of cold water and 3 parts of boiling water; it is also soluble in alcohol, and slightly so in ether; the aqueous solution is decomposed by exposure to the air; dissolved in hot oil of vitriol, it forms a deep, rich, red solution, which, when thrown into water, drops the gallic acid, deprived of some of its water. This substance is soluble in the alkalies, and dyes cloth like madder. When strongly heated, gallic acid is converted into metagallic acid, or into pyrogalllic acid, according to the manner in which the heat is applied. Its principal use is in the art of photography. It has been also employed in medicine, as an external astringent, but is, for that purpose, greatly inferior to tannic acid. *Imp. duty*, \$1 per lb.

**Gallipoli.** See ITALY, and TURKEY.

**Gallipot**, a small white earthenware pot or jar, used by chemists, etc.

**Gallivat**, a large rowing boat in the East Indies.

**Gallon**, the unit measure of capacity, consisting of 231 cubic inches = four quarts, or eight pints. This, the Winchester gallon of England, is the standard or wine gallon of the U. States, and also of the East and West Indies. The standard British measure, both for liquid and dry articles, is the *Imperial gallon*, which consists of 277.274 cubic inches, and should contain 10 lbs. avoirdupois of distilled water. In dry measure it is the eighth of a bushel.

**Galloo**, a narrow thick ferret or lace, commonly made of mohair or silk; but sometimes of wool, thread, gold, or silver. It is used as edging, and the common kinds are largely employed for binding hats, shoes, etc.

**Gallo-Tannic Acid**, a name for the pure tannin of nut-galls employed for chemical purposes.

**Gallows**, the frame supporting the beam of a steam-engine. — In printing, the rest for the tympan when open. — A beam laid over two posts, on which criminals are hanged.

**Gallows-Bitts**, a strong frame in the centre of a ship's deck to support spare spars when in port.

**Galls, Gall-Nuts, Nut-Galls** [*Fr. noix de galle*; *Ger. Galläpfel*; *It. galle*; *Sp. agallas*], are excrescences produced by the attacks of a small insect, which deposits its eggs in the tender shoots of a species of oak (*Quercus infectoria*), abundant in Asia Minor, Syria, Persia, etc. Galls are inodorous, and have a nauseously bitter and astringent taste. They are nearly spherical, and vary in magnitude from the size of a pea to that of a hazel-nut. When good, they are of a black or deep olive color; their surface is tubercular, and almost prickly; they are heavy, brittle, and break with a flinty fracture. They are known in commerce by the names of *white*, *green*, and *blue*. The white galls are those which have not been gathered till after the insect has eaten its way out of the nidus and made its escape. They are not so heavy as the others, and are of a lighter color, and do not fetch so high a price. The green and blue galls are gathered before the insect has escaped; they are heavier and darker than the former, and are said to afford about one third more of coloring matter. Galls are of great importance in the arts, being very extensively used in dyeing, and in the manu-

facture of ink, of which they form one of the principal ingredients. They are the most powerful of all the vegetable astringents; and are frequently used with great effect in medicine. Galls consist principally of three substances, — tannin or tannic acid, yellow extractive, and gallic acid. The decoction has a very astringent and unpleasant bitter taste. The ancients reckoned the gall-nuts of Syria superior to every other, and they still retain their pre-eminence. They are principally exported from Aleppo, Tripoli, Smyrna, and Said. Those from Caramania are of a very inferior quality. It is not unusual to dye the whitish gall-nuts blue, in order to increase their value. The fraud is, however, detected by the deeper blue tinge that is thus imparted to them; and by their being perforated and lighter than the genuine blue galls. *Imp. free.*

**Gall-Stone**, a calcareous concretion found in the gall-bladder of animals; it is sometimes used by painters as a yellow coloring matter, on account of its brightness and durability.

**Gallygaskins**, leather protectors for the legs of sportsmen during shooting excursions, etc.

**Galoche**, an overshoe; also, gaiters extending from the knee, and covering the instep.

**Galvanic Battery.** If we take a vessel containing water, to which some sulphuric acid has

Fig. 217. — GALVANIC BATTERY.

been added (Fig. 217), and plunge in the liquid a plate of copper, C, and a plate of pure zinc, Z, keeping the plates apart from each other, no action will be perceived, nor gas will be given off,

Fig. 218. — BUNSEN'S COMPOUND BATTERY.

nor will the zinc dissolve in the acid. But if the two plates be made to touch each other, or if a wire be attached to each plate, as shown in the figure, and the wires be brought into contact outside of the vessel, an action in the liquid is immediately perceptible at the surface of the copper plate, when a multitude of small bubbles of hydrogen gas will at once make their appearance, and the gas will

be given off continuously from the copper plate so long as there is metallic contact through the wires, or otherwise, between the two plates, or until the acid is saturated with zinc,—for in this action the zinc is dissolving, and, in consequence, liberating hydrogen, which strangely makes its appearance, not at the place where the chemical action really occurs, namely, at the surface of the zinc which is in contact with the acid, but at the surface of the copper which is not acted upon by the acid. The zinc, communicating its natural share of the electrical fluid to the acid, becomes *negatively* electrified. The copper, attracting the same fluid from the acid, becomes *positively* electrified, and any conductive substance, as the wires, placed within the line of communicating between the positive and negative points, will receive the charge thus to be obtained. It is known that when we establish a metallic communication between two bodies charged with equivalent quantities of positive and negative electricities respectively, these combine and neutralize each other, and all signs of electricity vanish. It is obvious that the contact of the two wires has this effect, as the signs of electric charge which were before discoverable in each of the plates are no longer found while the wires are in contact. But the charges reappear the instant the contact is broken, the chemical action ceasing at the same time. The arrangement of metals and acid which we have described is termed a *galvanic* (or *voltaic*) *couple*, *element*, or *cell*; and a series of cells joined together, as in Fig. 218, is a *galvanic battery*. A single cell is, however, commonly termed *battery*, while the term *compound battery* is given to a series of cells. See ELECTRO-METALLURGY, TELEGRAPH, etc.

Fig. 219. — GROVE'S BATTERY.

*Grove's Battery* (Fig. 219) is the most energetic battery yet known, and is the one most generally used for the magnetic telegraph. The metals employed are platinum and zinc, and the solutions are strong nitric acid in contact with the platinum, and sulphuric acid diluted with ten or twelve parts of water in contact with the zinc. This battery must be used with great care, on account of the strength of the acids used for the solutions, which send out injurious fumes, which are destructive to organic substances. The containing vessel, A, is glass; within this is a thick cylinder of amalgamated zinc, Z, standing on short legs, and divided by a longitudinal opening on one side, in order to allow the acid to circulate freely. Inside of this is a porous cell of unglazed porcelain, V, containing the nitric acid and strip of platinum. The platinum (shown separately in P) is fixed to a cover, C, which is placed on the porous cell. The amalgamated zinc is not acted upon by the diluted sulphuric acid until the circuit of the battery is completed. But, as the nitric acid will filter through the porous cell and act upon the zinc, it is advisable to remove the zinc from the acid when the battery is to remain inactive. *Bunsen's battery* differs only from this in the substitution of carbon to the plate of platinum. The Grove's and Bunsen's batteries are much more powerful arrangements than Daniell's (see ELECTRO-METALLURGY, Fig. 158), but the latter has the advantage as regards the duration and uniformity of its action.

**Galvanized Iron**, iron tinned by a peculiar process, whereby it resists the rusting influence of damp air, and even moisture, much longer than ordinary tin plate. It is made in corrugated sheets, and ranges from 800 sq. feet per ton, to 2,170 feet or more. It is either curved, step-corrugated, or corrugated with small flutes or channels.

*Manuf.* Clean the surface of the iron perfectly by the joint action of dilute acid and friction, plunge it into a bath of melted zinc, covered with sal-ammoniac, and stir it about till it be alloyed superficially with this metal; when the metal thus prepared is exposed to humidity, the zinc oxidizes slowly by the galvanic action, and protects the iron from rusting within it, whereby the outer surface remains for a long period perfectly white, in circumstances under which iron tinned in the usual way would have been superficially browned and corroded with rust.

**Galvanoglyphy.** See GLYPHOGRAPHY.

**Galvanometer**, an instrument constructed to measure minute quantities of electricity in galvanic operations.

Fig. 220. — GALVANOMETER.

A conductor traversed by a current, and placed above a magnetic-needle, but very near to it, and parallel to its axis, causes the needle to turn to the east or west, according as the current is moving from north to south, or south to north. If the wire is placed below the needle and parallel, as before, the effect is reversed. It follows, then, that when the conductor passes first above and then below the needle, so as to form two parallel lines between which the needle is suspended, the action of the current upon it will be similar in both cases; and the force thus produced is twice as much as that produced by a single conductor. By increasing the number of coils, the action of the current upon the needle can be so increased that very feeble currents can readily be detected. The conducting wire used must of course be insulated to prevent any direct metallic communication between the coils. There are several forms of *G.* The *astatic G.*, represented in Fig. 220, consists of an astatic needle placed in a coil of wire, so that the lower needle is within the coil, and the upper one above it. Its deflections are more considerable than those of a simple needle.

**Galvanoscope**, an instrument for detecting slight currents of electricity. Its construction is the same as that of the galvanometer, but, being used only to detect the presence of a current, it has no provision for measuring its strength or amount.

**Galveston.** See TEXAS.

**Galveston, Harrisburg, and San Antonio R.R.** runs from Harrisburg, Tex., to San Antonio, Tex., a distance of 215 m. This Co., whose offices are in Houston, Tex., was chartered in 1870, and the road opened in 1877, and has obtained from the State of Texas a land grant of 16 sections per m. *Financial statement:* Cap. stock paid in, \$4,638,794.40; represented by lands and bonds, \$1,811,205.60; total, \$6,450,000; funded debt, \$5,300,000; consisting of 1st mortgage bonds, issued 1871, \$4,300,000, payable 1910, interest 6% (Feb. and Aug.); 2d mortgage bonds, issued 1878, \$1,000,000, payable 1895, interest 7% (June and Dec.); floating debt, \$881,127.81; total cap. stock and funded and floating debts, \$12,631,127.81; per contra: cost of road, \$9,474,077.20; rolling stock, \$809,722.95; real estate, etc., \$1,702,572.29; stocks and bonds and other assets, \$1,018,328.65; total, \$13,004,701.41.

**Galveston, Houston, and Henderson R.R.** runs from Galveston, Tex., to Houston, Tex., a distance of 50 m. This Co., whose offices are in Galveston, was chartered in 1848. The road was opened in 1854, and in 1871 was sold under foreclosure and reorganized. *Financial statement, 1878:* Cap. stock, \$1,000,000; funded debt, \$1,500,000. 1st mortgage 7% bonds, issued 1871, payable 1902; per contra, construction and equipment, \$3,144,408.72; real estate, \$10,853.35; improvements since 1876, \$303,888.41.

**Galway.** See GREAT BRITAIN.

**Gama Grass**, a tall and esteemed fodder-grass, the *Tripsacum dactyloides*, native of Florida and Texas.

**Gambir, Gambier.** See CATECHU.

**Gamboge** [Fr. *gomme gutte*; Ger. *Gummigutt*; It. *gomma gutta*], a gum-resin, the product of a tree in Siam, the name of which is doubtful. It is inodorous, and nearly insipid to the taste. The best, the pipe-gamboge, is in rolls of a dull orange-color, having a conchoidal fracture, of a deep orange yellow, and a waxy rather than resinous lustre. It also occurs in cakes, fracture uneven, slightly porous, color less bright, and lustre more resinous. The larger cakes, and such as are dark colored, should be rejected. Genuine gamboge comes from Siam, and is imported to Europe generally by the way of Singapore or China. It is used as a pigment in water-colors, and as an ingredient in some varnishes. It is also a rough and violent cathartic. *Imp. free.*

**Gambroon**, a kind of twilled linen cloth for linings.

**Game**, a collective name for wild birds and animals which are coured or shot by sportsmen, and afford meats for the table.

**Gamel**, a rice measure on the east coast of Africa, of 38 lbs. weight.

**Gamene**, madder which has been dried and ground, without removing the outer pellicle.

**Gammon**, to deceive. — The salted and dried buttock of a hog, usually sold as bacon. — In Scotland, the feet of an animal.

**Gammoning**, a strong lashing, by which the bowsprit of a ship is secured to the cutwater.

**Gandang**, a bale of 25 pieces of cloth in the Philippine Islands.

**Gang**, a body of men employed together on any work. — A set of tools so connected that they act together, as a gang-plough, a gang of bits, etc. — A personal load, as much as can be carried at once. — A walk for cattle.

**Gang-Board**, a plank from a boat's side, resting on the shore, to step on.

**Gang-Casks**, small casks for bringing off water in boats.

**Ganger**, the foreman or manager of a gang of platelayers and laborers on a railway.

**Ganges.** See INDIA (BRITISH).

**Gang-Plough**, several ploughs stacked in one frame, usually supported on wheels and ridden by the operator.

**Gang-Saw**, an arrangement of saws placed parallel in a gate, so as to make a number of kerfs simultaneously, ripping up the log into lumber at one passage along the ways. In the large saw-mills of the lumber regions, these are known as *slabbing-gangs*, *stock-gangs*, *Yankee-gangs*, *live-gangs*, differing in certain particulars and purposes. — *E. H. Knight.*

**Gangue**, the matrix or portion of a rock in which an ore is deposited. — The superfluous earthy matter of a smelting-furnace.

**Gangway**, the passway or entrance into a ship by the steps on the side; a narrow passage among the cargo in the hold, to facilitate inspection, examine leaks, etc.

**Gannister**, a variety of sandstone, which, when ground and mixed with clay, is used for lining furnaces.

**Gant**, the French name for glove.

**Gantang**, a Malayan measure of capacity, containing 256 cubic inches. For grain, it is divided into 4 chupahs. In Malacca, the gantang of rice weighs 6½ lbs. avoirdupois; in Macassar, it is 8 lbs. 5 oz.; and in Java and Borneo it is even more.

**Ganza**, a small base coin in some parts of India beyond the Ganges, worth about 2 cents; also, a name in India for the dried leaves and flowers of hemp, an article of export from Bombay.

**Garance, Garancine.** See Madder.

**Garbage**, waste animal substances; the entrails of animals.

**Garbanzos**, the Spanish name for the chick pea, the grain or vetch of the *Cicer arietinum*; largely used as an ingredient in the famous olla podrida.

**Garbelled**, a commercial term for sorted or picked; formerly restricted to spices, but now applied to any kind of sorting.

**Garbling**, a commercial term for picking or sorting, hence the worst or refuse of any staple is called "garblings," or "garbles."

**Garce**, an Indian measure of capacity for grain, oil, seeds, etc., containing 12.8 maunds, or 400 marcals, and equal to 9,256½ lbs. The garce of Masulipatan is 156½ bushels.

**Garden**, a cultivated piece of land, usually near a dwelling-house, for raising fruit, flowers, or vegetables.

**Garden-Engine**, a watering-machine, with a small hose attached.

**Gardener**, one who has the charge, and attends to the management, of a garden.

**Garden-Labels**, wooden, metallic, or porcelain labels for the names of plants, to be fixed in the earth.

**Garden-Seat**, a rustic chair, or cast-iron seat.

**Garden-Tools**, spades, hoes, forks, rakes, and other appliances for cultivating and keeping a garden in order.

**Gargle, Gargarism, Throat-Wash**, a liquid medicine applied to the back part of the mouth or upper part of the throat. Gargles are applied by allowing a small mouthful to run as much as possible over the affected part, by holding the head backwards, and breathing through it, by which means the liquid is agitated, and its action promoted.

**Gari**, an Indian term for 4,000 rupees, or \$2,000.

**Garland**, a large rope or strap lashed to a spar when hoisting it on board a vessel. — A wreath of flowers.

**Garlic**, a perennial plant (*Allium sativum*), a native of Sicily, and cultivated for its root, which consists of pungent acriminous bulbs, of a strong and offensive smell. It is employed as a condiment, and is an ingredient in curries; it is also used in medicine. Besides the *G.* raised in this country, large quantities, packed in ceroon, are imported from Sicily and other parts of Europe.

**Garment**, any article of clothing, as a coat, gown, etc.

**Garner**, to store up.

**Garnet** (from Fr. *Grenat*, of the color of pomegranate seeds) is a precious stone, of which there are different kinds. The most valuable is the *Almandine*, precious garnet, or carbuncle, a beautiful crystallized mineral, of various shades of red, with sometimes a tinge of yellow or blue, or a smoky aspect. It is commonly translucent, often transparent. Principal localities, Ceylon, Pegu, and Greenland. Common garnet differs from the preceding, in being commonly opaque or only translucent; color, reddish, yellowish, greenish, or blackish brown. It is found in Scotland, Sweden, and other countries. *Pyrope* is a deep blood-red variety, in roundish and angular grains, completely transparent; chief localities, Germany and Ceylon. Others are distinguished by different names; as, *pyreneite*, which is a black variety; *grossular*, of a light olive-green color; *apone*, usually of a deep brown or orange-brown, and opaque; *manguesian garnet*, of a deep hyacinth or brownish-red; *melanite*, usually quite black and opaque; *colophonite*, of a greenish, yellowish-brown, or orange-red color; *allochroite*, of a grayish, dingy yellow, or reddish hue, and opaque; and *topazolite*, which is of a topaz-yellow. *Imp.* duty, not set, 10 per cent; set, 25 per cent. — A corn measure of Russia, the 64th

**Garnishee**, in law, a person in whose hands money or property belonging to a third person is attached; who is warned by a garnishment or notice not to pay the money, but to appear and answer to the suit of a plaintiff creditor.

**Garniture**, ornamental appendages or trimmings; the furniture or fittings to finish or embellish anything.

**Garrafon**, the Spanish name for a large stone jar in which spirits or cordials are sometimes shipped.

**Garret**, an uppermost room in a house, also termed an attic.

**Garreting**, small splinters of stone inserted into flint walls, or the joints of coarse masonry.

**Garrot**, in surgery, a tourniquet, consisting of a band and a stick, the former being twisted by the revolution of the latter.

**Garter**, a band, string, or ligament used to tie a stocking to the leg, so as to prevent it from slipping down.

**Garthe**, a weir or enclosure for catching fish in a river.

**Gas**, a permanently elastic aeriform fluid. The principal gases are the elementary bodies hydrogen, chlorine, oxygen, and nitrogen, and the compounds ammonia, carbonic acid, carbonic oxide, carburetted hydrogen, hydrochloric acid, phosphoretted hydrogen, protoxide of nitrogen, sulphuretted hydrogen, and sulphurous acid.

**Coal Gas, Gas-Light, Illuminating Gas.** The term *gas* is popularly applied to the mixture of inflammable elastic fluids obtained by the destructive distillation of coal or other carbonaceous substances. This gas was first evolved from coal by Dr. Clayton, in 1736-1739. — *Phil. Trans.* Its application to the purposes of illumination was first tried by Mr. Murdoch, in Cornwall, in 1792. The first display of gas-lights was made at Boulton and Watt's foundry, in Birmingham, on the occasion of the rejoicings for peace in 1802. Gas

was permanently used to the exclusion of lamps and candles at the cotton mills of Phillips and Lee, Manchester, where 1,000 burners were lighted, 1805. Gas-lights were first introduced in London, at Golden Lane, August 16, 1807. They were used in lighting Pall Mall in 1809, and were general through London in 1819. From that time its use steadily increased, until now it has become general in the towns and cities of the civilized world. In the U. States attempts were made to introduce gas

Fig. 221. — GAS MANUFACTORY.

part of a chetwert. — A purchase or description of tackle on the mainstay of a ship for hoisting cargo in and out.

**Garnice**, a measure of capacity in use in Poland, fixed legally at about 7 pints, but which varies in some parts of Russia.

**Garnish**, to embellish or beautify. — A Scotch law term, signifying to give notice, or warn.

about the year 1821. It began to be used in Boston in 1822, in New York in 1827, and in Philadelphia in 1835. From the best foreign cannel-coal are sometimes produced as high as 15,000 cubic feet of gas per ton; but from the coals in ordinary use, 9,000 to 10,000 feet per ton is an average yield. The price of gas varies, of course, with the cost of coal and labor. It ranges from \$2 to \$4 per 1,000

cubic feet in the principal cities. In some of the smaller towns, where the consumption is less, the price is considerably higher.

**Manuf.** The apparatus used in the manufacture of gas on the large scale consists essentially (Fig. 221) of a system of closed retorts, *a, a*, of cast-iron or fire-clay, generally having the form of a flattened cylinder, and arranged in sets of three or five, and heated by the same coal-fire. The quantity of coal takes about four hours for the coal to give off all its gas. When it has done this, the resulting coke is removed from the retort, and a fresh charge of coal is thrown into it, the mouth of the retort being then closed with a thick iron plate, and luted with clay. An iron pipe, *c*, ascends from the upper side of the front of the retort, projecting from the furnace, and, after describing a curve at its upper extremity, this iron pipe opens into a much wider tube, called the *hydraulic main*, *b*, which latter passes horizontally along the front of the range of furnaces, the tubes from all the retorts dipping into it. The hydraulic main is always kept half full of the water and the tar which condenses from the ascending gas; owing to which arrangement the opening into each retort is effectually closed by a water-valve, and thus permits a fresh charge of coals to be thrown in, and of coke to be withdrawn in any one or more of the retorts, without interfering with the distillation going on in the others. The aqueous portion of the liquid deposited in the hydraulic main, which is known as the *ammoniacal liquor*, and forms the principal source of the commercial salts of ammonia, passes off into cisterns, and the hot gas, after leaving the hydraulic main, passes into the *condenser*, *e*, which is composed of a series of bent iron tubes, these being kept cool either by the large surface they expose to the air, or, if necessary, by means of a stream of cold water applied to the outside. Any of the volatile hydrocarbons or salts of ammonia escaping condensation in the hydraulic main are arrested in the condensers, but not always; hence it is necessary to afterwards carry the gas through a *scrubber* (not figured in the plate) or case containing pieces of coke, over which a stream of water being made to trickle, absorbs any remaining ammoniacal vapors. The gas next passes through another series of vessels, called the *purifier*, *f*, containing quick-lime, of the consistency of cream, which cleanses the vapor of its sulphurous intermixtures. From the lime the purified vapor of the coal, or, in other words, the gas, now flows into one of the *gasometers*, *g*, or, more properly, *gas-holders*, which are the immense vertical cylinders forming such conspicuous objects at gas-works. Each gasometer is closed at the top, and floats with its open bottom in a tank of water. Some of them are telescopic in their action, to increase the internal capacity without increasing the diameter; the vast diameter of 160 feet is occasionally given to them. The substance is sheet-iron, tarred within and without, and strengthened in various ways with iron rods. Balance weights and chains enable the gasometer to float in the tank of water, and to rise in proportion as the gas accumulates in the inside. The water is to prevent any leakage of gas. The tendency of the gasometer to descend by its actual weight produces a condensing pressure on the gas within, and this pressure tends to drive the gas through miles of street pipe. The main pipes which proceed from the gas-works are large in diameter; those through the minor streets smaller; and those into the houses smaller still. The larger pipes are of cast-iron, in pieces 9 or 10 feet long, well jointed and luted. As some districts require more gas than others, as more is required in winter than in summer, as there is a large and sudden de-

mand every day just as night closes in, and as there is always less demand on Sunday than on week-days, a vast amount of consideration is needed in storing a sufficient quantity, and in making the pressure vary with the demand by the aid of *pressure-indicators* and *self-acting governors*. The smaller pipes, to convey the gas into houses, are often of lead or pewter. —The machinery of all gas manufactories is the same in principle, and seems now to be almost perfect. The chief improvements made in the machinery consist in the manner of applying to the gasometer the pressure which regulates the force of the gas.

Fig. 223. — Bat's-Wing Burner.

Fig. 224. — Fish-Tail Burner.

**Gasalier**, a chandelier with branches tipped with gas-burners.

**Gasoline**. See BENZOLE.

**Gas-Bracket**, a metal branch, which, proceeding from a wall, connects a burner with the gas-pipe.

**Gas-Burner**. This is nothing more in principle than an orifice, or a row of orifices, through which the gas escapes from the pipe, to be burned as a jet; but as the object in view is to cause every atom of gas to produce flame, much ingenuity has been displayed in so arranging the orifices as to attain this end. If contact with the external air is not sufficiently complete, some of the gas will go off in a non-luminous state, either as invisible gas or as smoke. The glass chimney, generally used around and above the flame, regulates the mode in which the air gets access to the gas; and the numerous forms given to it are indicative of the large number of experiments which have been made on the subject. Various arrangements of the orifices give rise to forms of *B*. among the best known of which are:

the *bat's-wing B*. (Fig. 223), consisting of a nipple, *a*, generally of cast-iron, across which the gas escapes in a thin fan-like flame. The *fish-tail B*. (Fig. 224), which is made by two oblique orifices (*a*), so that two streams of gas impinge against each other, producing divergence, and bringing the carburetted hydrogen in contact with the air. The *cog-spur B*. has three apertures, one central and the others divergent. The *Argand B*. (Fig. 225) consists of a ring pierced with holes rounded with a glass shade to regulate the supply of air and steady the flame. The *Bude's, Frank-*

Fig. 225. — ARGAND BURNER.

mand every day just as night closes in, and as there is always less demand on Sunday than on week-days, a vast amount of consideration is needed in storing a sufficient quantity, and in making the pressure vary with the demand by the aid of *pressure-indicators* and *self-acting governors*. The smaller pipes, to convey the gas into houses, are often of lead or pewter. —The machinery of all gas manufactories is the same in principle, and seems now to be almost perfect. The chief improvements made in the machinery consist in the manner of applying to the gasometer the pressure which regulates the force of the gas.

land's, Leslie's, Winfield's, etc., are modifications of the Argand B. The *sunlight*, or *Furaday's ventilating B.* consists of a ring of common burners set in the base of a reflecting cone that passes through the ceiling, and conducts away the products of combustion, and thus lights and ventilates the room at the same time. The *Union B.* consists of a row of holes so contrived that the jets touch and nearly coalesce, each, however, preserving partly its distinctiveness.

**Gaselier, Gazifere**, an apparatus for making aerated waters.

**Gas-Engine**, an engine in which gas is applied as a prime mover instead of either steam or air. In *Lenoir's gas-engine*, now much employed in France, the source of power is the expansion arising from the explosion of gas. It is, in truth, an *air-engine*, *gas-engine*, and *galvanic-engine* all in one. Air and gas are admitted to the cylinder in the preparation of 11 to 1; a spark from a galvanic battery is sent through it; the spark explodes the mixture; and the expansion consequent on this explosion drives a piston to the other end of the cylinder. Mechanism does all the rest,—opens a slide-valve to afford exit for the exploded mixture, drives the piston back by the momentum of a fly-wheel, opens tubes for the admission of new air and gas, establishes connection again with the battery, and prepares for the renewal of the action; and so on continuously. These engines are

Fig. 226. — GAS-ENGINE.

costly in the first instance, and many precautions are necessary to prevent them from being overheated; but they require no stoker, and are rather cheaper to work than a steam-engine: consequently, they are much employed for two to four horsepower purposes. — The *Otto Silent Gas-Engine* (Fig. 226) consists mainly of a jacketed cylinder, with piston, slide-valve, and governor, having a cut-off mechanism to regulate the supply of gas according to the varying load on the engine. The pressure utilized for the production of the power is generated in the cylinder, and at once availed of therein to propel the piston. This pressure is due to the combustion of a peculiar mixture of common coal gas and air, which is ignited by a small flame, carried from a burning gas-jet outside into the cylinder by the motion of the slide.

**Gas-Fitter**, one who fits up the pipes, brackets, burners, etc., for gas-lighting. The term *gas-fitting* is applied to the different contrivances for the application of gas-lighting, consisting of pipes, services, meters, burners, etc.

**Gas-Fitter's Tongs** are tongs for holding gas-pipes while screwing joints together.

**Gas-Fixtures** are the ornamental fittings or appendages at the extremity of the pipes which conduct gas from the meter to the different apart-

ments of a building, as brackets and gasaliers (Fig. 222), including stopcocks and burners. Gas-fixtures are included among the specially artistic productions of industrial skill in this country. Great taste is shown in designing and manufacturing them, and the principal houses engaged in their production are constantly vying with each other to produce new effects of style and finish.

**Gas-Furnace**, a small furnace now much used in laboratories. The burner is so contrived that a stream of common gas is made to give as much heat as possible, without any regard to the light produced; which is just the reverse of the object sought to be obtained in gas-lighting.

**Gas-Gage**, an instrument for ascertaining the pressure of gas.

**Gas-Generator**, a chamber, machine, or retort, in which gas is evolved.

**Gas-Governor, Gas-Regulator**, an apparatus employed to regulate and equalize the pressure of gas when flowing for burning.

**Gas-Heater**, an apparatus, of which there are many forms, in which gas is applied to the specific purposes of heating or cooking. One of these contrivances depends on the use of *asbestos*, a substance which may be brought to a white glowing heat without actually burning or consuming. A kind of grate is formed, with hollow tubes instead of iron bars; the tubes communicating end to end, and being ranged parallel, further back at the upper rows than the lower. \*The tubes are gas-pipes, and small perforations in them serve as jets. The gas might simply be lighted in this form, producing minute jets of flame; but this would not imitate the appearance of an ordinary open fire. The grate is therefore filled up with asbestos shavings, which soon present a dazzling mass of white-hot fire, with gas-flames darting up through all the interstices. This of course requires that the fireplace be made on purpose, and that the tubular bars should be placed in connection with the gas-pipes of the house. *Ward's Stove* has a row of gas-jets near the bottom of an iron case roomy in length and breadth, but very shallow from front to back. It is not an open fireplace, but a close stove, which heats a large surface of sheet-iron by the consumption of a small amount of gas. *Graham's Cooking-Stove* has a considerable length of gas-pipe, twisted about in horizontal coils a little below the upper horizontal plate. The coils are so placed that immediately over them the plate can be opened, and saucepans and vessels of various kinds exposed to the direct asscensive heat of the gas, issuing in numerous ignited jets from holes in the pipe coil. Some of the coils are made applicable for roasting, some for baking, some for heating water in a boiler; and the action of all the coils is governed by appropriate stopcocks.

**Gas-Holder**, a large reservoir for containing gas; a gasometer. See *Gas*.

**Gaskets**, on shipboard, plaited cords, or small ropes, used to secure a sail to the yard, or boom, when it is furled.

**Gaskins**, packings of hemp; wide open hose.

**Gas-Light**, a jet of flame from ignited coal-gas. See *Gas*.

**Gas-Mains**, the large iron supply-pipes by which the gas is distributed from the manufactory to different localities in a town.

**Gas-Meter**. In the measurement of gas, to determine how many cubic feet the company shall charge to the consumer, a *meter* is used, which is constructed in one or other of many different ways. (1.) *Wet Meter*. This consists of a kind of

drum, divided into compartments, all of equal and known capacity. The drum revolves in water, in which it is rather more than half immersed. There are numerous modes of arranging the different parts of the apparatus; but the general action is this,—all the gas from the street-mains to the house pipes pass through the meter; every cubic foot so passing gives a certain portion of one revolution to the drum on its axis; and this revolution, through a train of wheels, acts upon index-hands, which tell of 1,000, 10,000, 100,000, 1,000,000, etc., cubic feet of gas. (2.) *Dry Meter*. Sometimes it is found that the water in the wet meter freezes in cold weather, and that some of the gas passes through without being registered. To obviate these defects, many of the companies prefer *dry* meters. In these the gas is measured by the number of times that a certain quantity will fill a chamber capable of undergoing contraction and expansion by the passage of the gas. For this purpose the partitions in the meter are made of flexible leather instead of inflexible metal. The undulations of the leather affect certain arms and levers, which in their turn give motion to wheels and index-hands. The flexible leather being the characteristic of this class of meter, as water is of the other class, the particular modes of developing the action are very numerous. To suit the requirements of different establishments, meters are supplied of various sizes, known by the number of lights which the gas is fitted to supply,—such as 2-light, 10-light 50-light meter, and so on. A definite arrangement is made between the company and the consumer in regard to the meter; and care is taken that the interior of the meter shall be so placed under lock and key as not to be tampered with.

**Gasometer.** See GAS.

**Gasoscope,** an apparatus for indicating the presence of bicarburetted hydrogen gas in buildings, mines, etc.

**Gaspereaux,** a name for the alewife.

**Gas-Pipe.** See GAS.

**Gas-Register,** an instrument by which the pressure of gas is indicated and recorded.

**Gas-Regulator.** See GAS-GOVERNOR.

**Gas,** a money of account in Persia, the twentieth part of a manoodi, and worth rather more than half a cent.

**Gassing,** the process of singeing net, lace, etc., in order to remove the hairy filaments from the cotton. It is performed by passing the material between two rollers, and exposing it to the action of a large number of minute jets of gas.

**Gas-Socket,** the metallic socket which slips over the tip of a burner, and connects the elastic gas-tubing therewith. — *E. H. Knight*.

**Gas-Stove,** see GAS-HEATER.

**Gas-Tar,** the bituminous and very complex substance which distills over in the manufacture of coal-gas. From it are now obtained benzol, toluol, phenol, naphthalene, and anthracene, which give us the brilliant aniline colors.

**Gas-Works,** the plant and general buildings belonging to a gas-company.

**Gate,** a doorway or entrance, of which there are various kinds. The term is now chiefly applied to any light, swinging wooden or metal construction, as a wicket-gate, garden-gate, turnpike-gate, etc. In founding, the gutter or hole through which the molten metal is poured; also a founder's name for a ridge in a casting, which has to be sawn off.

**Gate-Hinge,** a long strong hinge for suspending a gate by.

**Gate-Way,** an entrance to some enclosed place.  
**Gattie,** the name of an East Indian soluble gum, obtained from the common babool, or *Acacia Arabica*; it is very similar to the African gum arabic.

**Gaub,** an Indian name for the fruit of *Diospyros embryopteris*, which, when expressed, exudes an excessively astringent juice, yielding 60 per cent of pure tannic acid. It is used in medicine as an astringent and styptic, and is employed in Bengal for paying the bottom of boats.

**Gaucha,** a mounted herdsman in Patagonia and Buenos-Ayres.

**Gaufering,** is a manner of plaiting or crimping where the flutes are unusually wide.

**Gauge, Gauging.** The term *gauge*, or *gage*, is used in different ways, but always with reference to measure or proportion; or, in the literal sense of the word, to that which bounds or confines something else. Thus, in physics, it is applied to several instruments or apparatus for measuring the state of a phenomenon; such as the wind-gauge, rain-gauge, the barometer-gauge for measuring the degree of pressure of the air within the receiver of an air-pump, etc.; in architecture, to the length of a slate below the lap; in railway-engineering, to the space between the rails, and the like. *Gauging* is the art of measuring dimensions, direction, and intensities of different kinds.

The maintenance of uniform or standard dimensions in machine fitting is fast becoming a rule and almost a necessity, enhancing the value of what is made, and at the same time cheapening the cost of production by permitting a more extended division of labor. The division of labor in machine fitting depends on what may be called duplication, that is, producing one thing like another, so that different workmen may, independent of each other, prepare parts or pieces which can be assembled and put together without trying and hand fitting. The export of American-made machines to Europe commenced, it may be said, because of an early and successful application of the gauging system. One of the first and most important orders received from Europe for machinery was for a nearly complete equipment of implements for the Enfield small-arms factory, in England: machines and tools the main object of which was a duplication of their product. Watches, clocks, sewing-machines, small arms, with many other articles of a similar kind, are now made in this country and sold in Europe, because the system of gauging and duplicating offers an advantage overbalancing cheaper labor, cheaper material, and more than 3,000 miles of ocean carriage. Most of our larger establishments have been supplied with standard gauges imported from England, and corresponding to what is called the Whitworth standard. Most of these gauges are made in the works of the Whitworth Company at Manchester, who by long experience and their reputation for good work have controlled this manufacture. Of late years, however, some fine examples have been made in this country, but at prices much greater than are demanded for English gauges. The British and American standards for lineal measure are the same. The British standard is an arbitrary one, fixed after several years of labor on the part of a learned commission and at considerable expense. The pendulum test, which was the only natural one by which experiments were made, was abandoned after thousands of readings showed its inconsistency. The French metre of the forty-millionth part of the earth's meridian, as well as all other natural standards, were abandoned for the same reason, and the wisdom of this course has been proved by the French government since adopting an arbitrary standard the same as the English had done. In this country, while there has been more spent in preparing comparative standards than by any other government in the world, there has been no search, so far as we know, after natural or other standards. The equipment of implements of transmission and for measuring exceeds that of which any other country can boast, but the principal wisdom shown in the matter has been in avoiding the useless expense of fixing an independent standard which might be anything. By comparison, under similar conditions, a metal test-rod adjusted at Washington, and a similar one adjusted at London, would show a difference due to ten degrees of temperature, and this is no doubt the only difference. It is enough to know that gauges made to a carefully adjusted standard here will match and interchange with those made in England. The term *gauging* is commercially applied to the method of determining by actual measurement the number of gallons contained in vessels intended to hold goods,—chiefly casks, barrels, vats, etc. The principal use of gauging is in the collection of the

revenue, in which it is necessary to measure the bulk of vessels, without disturbing their contents. The principles of gauging are those which are furnished in geometry for the measurement of solids. As, however, the men who are engaged either in commerce or by the excise for the purpose of gauging are not likely, in general, to be acquainted with the principles upon which the art depends, a set of technical rules and appropriate instruments have been contrived, by which the art can be practised by any one of moderate intelligence. The instrument usually employed is the gauging rod, or diagonal rod, by which the contents of a cask are inferred from its diagonal length, measured from the bung-hole to the extremity of the opposite stave at the head. A scale of inches, for taking the measure of the diagonal, is described on one face of a square rule, usually about four feet long, and on the opposite face is a scale expressing the corresponding contents of the cask in gallons. Although this method, obviously, can only give approximate results, yet by using larger sliding-rules for calculation, and the aid of habit, derived from experience, it is possible to attain considerable accuracy in measuring the contents of casks, which do not depart from a given standard of form. The rates for gauging in New York are generally 12 cents for a cask; 4½ cents for cases and baskets; and 1½ cents for a dozen bottles of porter, ale, and beer.

**Gauger**, an excise-officer, a measurer of the contents of casks, etc.

**Gauntlet**, a long glove which covers the wrist.

**Gauze**, a very light and transparent textile fabric, woven of thread and silk, and sometimes of thread only; it is made either plain or figured. The best comes from France and Switzerland.

In the ordinary processes of the loom, the warp threads are always kept parallel, in whatever way the weft threads may be twisted around them. But in making *gauze* two adjoining warp threads are completely twisted round each other between two throws of the shuttle or casts of the weft. Some peculiar appendages to the loom are required to effect this. One consequence of the mode of interlacing is, that the texture is light, the weft threads being further apart than would be practicable in other webs. In appearance, as well as in mode of producing, gauze occupies a kind of medium position between plain weaving and plain lace or bobbinet.

**Gauze Ribbon**, a thin kind of ribbon made of gauze.

**Gauze Wire-Cloth**. See **WIRE-CLOTH**.

**Gavel**, a loose-lying heap of wheat, rye, or other grain; enough to be bound in a sheaf.

**Gayal**, a name in some parts of India for the *Aque vivipara*, a cordage plant.

**Gaze-à-blutoir**, a very thin kind of silk gauze, used by millers in France for bolting-cloths, which has been made as fine as 220 threads to the inch.

**Gazlich**, a cotton fabric made in Turkey.

**Gazzies**, mixed caravans in Africa, on a smaller scale than kafilahs, and comprising camels, mules, asses, and men and women.

**Gea**, a name in some of the Pacific islands for the breadfruit.

**Gear**, accoutrements; apparatus; harness. A general term for the several working parts of a locomotive, or of any machinery. See **GEARING**.

**Gearing**, a term applied to the parts of machinery by which motion in one part of a machine is communicated to another. *G.* consists in general of toothed wheels, friction wheels, endless bands, screws, etc., or of a combination of these. When the communication between the two parts of the machine is interrupted, the machine is said to be *out of gear*; and when the communication is restored, it is said to be *in gear*. *G.* which can be put in and out of gear is called *movable G.*; that which cannot, as, for instance, the wheelwork of a watch, is called *fixed G.* *Straight G.* is used when the planes of motion are parallel to each other; *bevelled G.* when the direction of the plane of motion is changed. *G.* has also for its object the increasing or diminishing of the original velocity, and in reference to this is distinguished by the term "multiplying" or "retarding."

**Gebräude**, a name in Germany for the quantity of beer brewed at one time; in Berlin it is a liquid measure of about 106½ gallons.

**Ged**, a Scotch name for the pike fish.

**Geira**, a land measure of Portugal, about 7,000 sq. yards.

**Gelatine** [Fr. *gelatine*; Ger. *Gallert*, *Lem*] is animal jelly, obtained by the prolonged action of boiling water on the organic tissue of the bones, tendons, and ligaments, the cellular tissue, the skin, and the serous membranes. Glue and size are coarse varieties of *G.*, prepared from hoofs, hides, skins, etc.; and isinglass is a purer kind, obtained from the air-bladders or some other membranes of fish. *G.* is insoluble in cold water, but dissolves with greater or less readiness on the application of heat, according to the source where it is obtained, and in this state forms a tremulous and transparent jelly on cooling; it is insoluble in both alcohol and ether, and is decomposed by the strong alkalies and acids. Alcohol and tannic acid precipitate *G.* from its solution; the former by abstracting the water, the latter by combining with the substance itself into an insoluble compound, of the nature of leather. No other acid except the tannic, and no alkali, possesses the property of precipitating *G.* But chlorine and certain salts render its solution more or less turbid; as the nitrate and bichloride of mercury, the protochloride of tin, and a few others. Sulphuric acid converts a solution of *G.* at a boiling heat into sugar. *G.* is largely employed as an article of food, as in soups, jellies, etc.; but its value in this respect has been, perhaps, overrated. Animals fed exclusively on *G.* die of starvation. But when mixed with other food, especially with substances abounding in albumen, casein, or fibrin, *G.* may be useful as an aliment, and serve directly to nourish the gelatinous tissues. The *G.* is also used as a material in the dressing of stuff goods, as a refining ingredient in the clarification of wine, as a chemical test for tannin, in photography, in the manuf. of cements, in confectionery, for artificial flowers, in pharmacy for coating pills and making capsules, etc. *G.* is imported chiefly from France, in thin sheets of semi-horny texture, without taste or smell, colorless and transparent, and varying in toughness according to the tissues from which it is prepared. It is also extensively manufactured in New York. One reason why the French have made so much advance in the manuf. of *G.* is, that there are in that country well-arranged and systematic establishments for the slaughtering of cattle, sheep, swine, and horses; affording great facilities for the economical application of the hides, skins, bones, tendons, ligaments, and other gelatinous tissues. They excel in producing different kinds of *G.* in thin sheets; pure and white films cut into threads for the use of the confectioner; very thin, white, and transparent sheets, called "papier glace," or ice-paper, for copying drawings; dyed, gilt, and silvered gelatine sheets, adapted to the fabrication of artificial flowers and to the production of an almost endless variety of ornamented articles; and sheets embossed or stamped with elegant patterns. *Imp. duty*, 35 per cent.

**Gelatine Process**. See **PHOTOGRAPHY**.

**Gelding**, a castrated horse.

**Gelso** [It.], the mulberry-tree.

**Gemel-Hinge**, in locksmithing, a hinge consisting of a loop and a hook.

**Gems**. See **PRECIOUS STONES**.

**Gen**, a kind of manna obtained in Persia, Arabia, and other Eastern countries, from the camel's thorn, *Hedysarum alhagi* of Linn. It is collected from the branches by the Arabs and caravans which cross the desert, and is used as food.

**Genappe**, a worsted yarn or cord used in the

manufacture of braids, fringes, etc.; its smoothness enabling it to be well combined with silk.

**General Average.** See AVERAGE.

**General Order Store,** a government bonded warehouse to which, under a "General Order," all foreign merchandise is sent that is not claimed by the owner or consignee within a certain number of hours or days after the arrival of a vessel in port; the owner and the goods are answerable for the expenses of cartage, storage, etc. — *T. McElrath.*

**Generator,** a vessel for generating steam from water (see BOILER). — An apparatus for generating carbonic acid for charging bottles, etc., with soda and mineral waters (see SODA-WATERS). — A retort in which coal-gas is generated (see GAS).

**Geneva.** See HOLLANDS.

**Geneva, Ithaca, and Sayre R.R.** runs from Geneva, N. Y., to Sayre, Pa., a distance of 75.63 m. This Co., whose offices are in Philadelphia, Pa., was organized by the consolidation of the Geneva and Ithaca R.R., and the Ithaca and Athens R.R. In 1875 it was placed in the hands of a receiver, its interest having defaulted, and was subsequently bought in the interest of the Lehigh Valley R.R. Co. *Financial statement:* Cap. stock, paid in, \$850,000; funded debt, \$600,000 7% bonds, issued 1870, interest Jan. and July; floating debt, \$192,248.06; total stock, bonds, and debt, \$1,642,248.86. Per contra: cost of construction and equipment, \$1,481,297.06.

**Genevrette,** a wine made of juniper-berries.

**Genoa.** See ITALY.

**Gentian** [*Fr. gentiane*; *Ger. Enzian*; *It. genziana*; *Sp. jenciana*], the roots of two alpine plants, *Gentiana lutea* and *Gentiana purpurea*, found growing in Switzerland and Austria, the Apennines, the Pyrenees, and in North America. Those brought to this country come from Germany. They are in pieces of various lengths and thickness, twisted and wrinkled on the outside, and covered with a brownish-gray cuticle. They have no particular odor, and the taste is intensely bitter, without being nauseous. It was formerly a favorite remedy in agues.

**Gentianin,** a substance obtained from the root of common gentian. It forms golden-yellow needles, scarcely soluble in cold water, but very soluble in alcohol and ether. It is a powerful bitter and stonachic.

**Gentionella Blankets,** a heavy, closely woven woollen fabric, used for coatings and wrappers, and somewhat resembling pilot-cloth.

**Geometric Pen,** an ingenious instrument for drawing geometric curves, in which the movements of a pen or pencil attached to a revolving arm of adjustable length are varied by changing the toothed wheels which give motion to the arm. — *Webster.*

**Georgetown,** a city and port of entry of the U. States, in the District of Columbia, at the head of the Potomac River navigation, about 125 m. from the sea, and 2 m. W. N. W. of Washington. Large quantities of flour are barrelled there, and the coastwise trade is considerable. *G.* possesses 99 vessels, having an aggregate tonnage of 8,760. In 1878, 232 vessels (tonnage 96,329) entered, and 91 vessels (tonnage 43,624) cleared the port. Pop. 13,000.

There is another port of entry of this name in South Carolina, for which see SOUTH CAROLINA.

**Georgia,** a southern State of the U. States, lying between lat. 30° 22' and 35° N., lon. 81° and 85° 30' W. It is bounded N. by Tennessee and N. Carolina, N. E. and E. by S. Carolina and the Atlantic, S. by Florida, and W. by Alabama. Ex-

treme length from N. to S. 320 m., breadth 251 m. Area, 58,000 sq. m. Pop. about 1,300,000. The coast line of *G.* extends about 100 m., and is skirted by a series of low, flat, sandy islands, leaving but four navigable entrances without, — at Savannah, Darien, Brunswick, and St. Mary's. The mainland for about 50 m. into the interior is perfectly level, and for several miles from the seaboard consists of a salt marsh of recent alluvium; the whole of the flat country is intersected by swamps, which are estimated to constitute one tenth of the whole State. At the extremity of the low country there is a barren sandy tract of rather greater elevation, which extends N. as far as the river falls, and is generally regarded as dividing the upper from the lower country. Farther N. the surface becomes gradually more hilly and broken, and the N. extremity of the State comprises some of the most southern ridges of the Appalachian mountain chain, which here rise to about 1,500 feet above sea level. The rivers are the Savannah, 600 m. long, bounding the State on the N. E., navigable for ships 17 m. to Savannah, and a part of the year for steamboats 250 m. to Augusta, the Altamaha, which is navigable for large vessels 12 m.

Fig. 227. — SEAL OF GEORGIA

to Darien, is formed by the junction of the Oconee and the Ocmulgee, and is navigable for sloops of 30 tons by the former to Darien, 300 m. from the ocean; the Ogeechee, 200 m. long, and navigable for sloops 40 m.; Flint River, which rises in the N. W. part of the State, and, after a course of more than 200 m., joins the Chattahoochee, forming the Appalachicola; the Chattahoochee, on the W. border of the State, which is navigable 300 m. by steamboat to Columbus; and the St. Mary's River, in the S. W. part of the State. The soil of *G.* is, for the most part, highly productive. In the low country and the sea-islands it consists of a light-gray sand, gradually becoming darker and more gravelly toward the interior. Farther N. it is a black loam mixed with red earth, called the *mulatto soil*; this is succeeded in the more remote districts by a rich black mould of superior fertility. The mineralogical resources of *G.* are, as yet, but only partially developed. Gold has been found in considerable quantities in the N. districts, and in 1879 there were over 400 stamps in operation in the 40 gold mills in the State. Considerable investments of capital were made of late in the gold-mining region, especially in the neighborhood of Dahlonega. The yield of gold was fairly profitable in 1878, and greater results are anticipated. The portion N. E. of the State, which embraces the main developments in gold-mining, and the most striking characteristics of mountain, valley, and waterfall in *G.*, lies within Cherokee, Forsyth, Hall, Dawson, Lumpkin, White, and Habersham Counties, a belt about 100 m. long and 30 m. wide, N. of and immediately along the Atlanta and Charlotte Air-Line R.R. This region was the favorite part of the Cherokees' reservation, and to the eye it seems that no region on the globe can surpass it in extent and variety of beautiful views. The vision can here frequently sweep unbroken for more than a hundred miles over the most noble landscapes. — *Climate.* The N. parts of *G.* are

very healthy, and the winters mild; frost and snow frequently occur, but are not severe or of long continuance. Hurricanes and thunder-storms frequently occur in the fall, at which season the agriculturists and planters generally remove either to the islands, or the most N. districts of the State. In the low region the thermometer usually ranges during the summer from 76° to 90° F., but it has been known to stand as high as 102° F. — *Forests.* The tops of the hills are mostly crowned with forests, composed chiefly of the pine, palmetto, oak, ash, cypress, hickory, black-walnut, mulberry, and cedar trees. The growth along the riparian bottoms is of canes, cypress, magnolia, gum-woods of different species, including the liquid-amber tree, oaks, tulip, sweet bay, and many other genera; while upon the sandy lands pines and scrub-oaks form almost the sole arborescence. — *Agricultural Products.* The principal are cotton, wheat, and other European grains, maize, tobacco, the sugar-cane, indigo, rice, etc. The coast islands yield large quantities of the fine description of long-staple cotton known as *sea-land*. The proportion of productive land is much greater in the hilly country than in the plains. In 1878 the returns of wild land in the State showed 7,582,323 acres, valued at 22 cents per acre. — *Commerce and Industry.* Cotton is the great commercial staple; and it and tobacco, indigo, canes, timber, deer-skins, and maize form the leading articles of export; the sugar-cane has hitherto been cultivated mostly for home consumption only. Besides the exports from Savannah (see below), great quantities of produce find their way annually to Charleston, S. C., for shipment, and also coastwise to the more N. ports. The imports consist chiefly of textile and other manufactured goods, E. India produce, wines from the S. of Europe, and butter, cheese, fish, etc., from the N. States of the Union. The manufacturing interests of G. lie principally in the fabrication of cotton and woollen stuffs, and the smelting, founding, and working of iron. There are in operation about 20 mills containing 70,000 spindles, which spin annually about 11,000,000 lbs. of raw cotton.

The material condition of the State for 1878,

as compared with the previous year, was as follows: —

DESCRIPTION OF PROPERTY.	Value in 1877.	Value in 1878.
Improved land .....	\$87,182,903	\$84,608,700
Wild land .....	1,700,518	1,656,773
City and town property .....	51,230,726	48,370,413
Building and loan associations .....	244,323	231,198
Bank shares .....	5,467,497	4,931,797
Money and solvent debts .....	27,156,216	26,130,351
Merchandise .....	11,424,500	11,168,425
Capital invested in shipping .....	153,848	62,048
Stocks and bonds .....	5,550,272	4,997,984
Cotton manufactories .....	2,739,500	2,772,670
Iron-works, etc. ....	23,336	226,330
Capital invested in mining .....	72,516	71,396
Household and kitchen furniture .....	9,959,093	9,463,475
Watches, jewelry, etc. ....	1,089,323	1,057,920
Horses, mules, etc. ....	22,736,494	21,421,810
Plantation, and mechanical tools .....	2,933,216	2,858,338
Corn, cotton, held for sale April 1st .....	673,390	792,200
Other property .....	4,191,443	4,163,586
Defaulters' property single .....	861,638	670,351
Aggregate value .....	\$235,650,550	\$226,221,718

On Jan. 1, 1879, there were in G. 12 national banks, whose aggregate capital was \$2,041,000; and 67 state banks, savings-banks, and private bankers, with an aggregate capital of \$4,317,817. No State in the Union is more solvent, and should have a stronger financial reputation than G. On Jan. 1st, 1879, the debt of the State was only \$10,444,500, a small part of which is yearly liquidated.

*Atlanta*, the capital of G. (pop. 40,000) and the terminus of all the railroads of the State, is a fine city and a place of considerable commercial importance. Its favorable position and its spirit of enterprise mark it as the future metropolis of the S. E. States. The other cities and towns of importance are Savannah, Augusta, Milledgeville, Macon, Columbus, Rome, Athens, Brunswick, and St. Mary's.

The following table, reprinted from the valuable *Manual of the Railroads of the U. States for the year 1879*, by H. V. Poor, gives the mileage, cost, earnings, and dividends of the railroads of the State in 1878; their total length on Jan. 1, 1879, being 2,414.92 miles: —

NAME OF COMPANY.	RAILROAD.		Cost of railroad, etc., per mile. Dollars.	Length of railroad worked. Miles.	REVENUE PER MILE.			Dividends paid in 1868. Per cent.
	Total miles.	Miles in Ga.			Earnings Dollars.	Expenses Per cent.	Profits. Dollars.

*G.* has the three following ports of entry : —  
**Brunswick**, in lat. 31° 10' N., lon. 81° 35' W., 80 m. S. S. W. of Savannah. It has a spacious and commodious harbor, having 13 feet of water on the bar at the lowest tides. It is situated on Turtle River, 14 m. above the bar. Its commerce has considerably increased of late, and has a direct trade with Europe. 30 vessels, with an aggregate tonnage of 3,369, belong to this port. In 1878, 383 vessels (tonnage, 139,330) entered, and 310 vessels (tonnage, 154,304) cleared the port. The value of foreign imports in 1878 was \$1,046, and of exports, \$999,105. Pop. 4,000.

**Saint Mary's**, in Camden Co., on St. Mary's River, about 9 m. from its mouth. Its commerce and pop. are small.

**Savannah**, in lat. 30° 4' 56" N., lon. 81° 8' 18" W., is a fine city on the right bank of the Savannah River, 17 m. from its mouth. The harbor is good. Vessels drawing 14 feet water come up to the city, and larger vessels anchor at Five Fathom Hole, four miles below the city. The commerce of the place ranks next to Mobile, and is the most important port, except Charleston, from Baltimore to Mobile. The greater part of the trade of *G.* centres at Savannah, the principal articles of which are cotton, rice, and lumber. The Savannah River affords great facilities for internal commerce; and this river is connected with the Ogeechee River by a canal 16 miles long, which terminates at Savannah. In 1878, 682 vessels (tonnage, 593,183) entered, and 663 vessels (tonnage, 576,231) cleared the port. 67 vessels, with an aggregate tonnage of 15,972, belong to the port of Savannah. The total value of foreign exports for the year 1878 was \$18,544,963; and of imports, \$502,721. Pop. about 25,000.

**Georgia R.R. (and Banking Co.).** This road runs from Augusta to Atlanta, Ga., 171 m., with branches from Camak to Washington, 4 m.; from Union Point to Athens, 39 m.; and from Barnett to Washington, 17 m.; total, 231 m. The Co., whose offices are in Augusta, Ga., was chartered in 1833, and the road completed in 1845. The Co. owns, jointly with the Central R.R. of Georgia, the Western R.R. of Alabama, also one fifth of the Port Royal & Augusta R.R., and entirely the Macon & Augusta R.R., making a total of 413 m. owned entirely or in part by this Co. *Financial statement*, March 31, 1879: Cap. stock, \$4,200,000; 6% bonds, \$1,000,000; 7% bonds, \$483,000; other liabilities, \$596,597.11; total liabilities, \$6,279,597.11. Per contra: construction of road and outfit, \$4,200,000; purchase account, Western R.R. of Ala., \$817,973.76; one fifth interest in P. R. & A. R. R., \$200,000; stocks, bonds, real estate, cash, etc., \$1,572,946.64; total assets, \$6,790,920.40.

Fig. 228. — GERANIUM.

**Gerah**, an Indian cloth measure, equal to 24 inches.

**Geranium**, the crane's-bill, an extensive genus of handsome flowers, in which a large trade is carried on by nurserymen. The *G. maculatum*, with flowers of considerable beauty, is the most valuable medicinal plant of the genus. An essential oil, used in perfumery, is obtained from *G. platypetalum* (Fig. 228), and some other species; but it is much inferior to the essential oil of the same name, also called *Turkish essence*, and oil of *Ginger-grass*, which is employed by the Turks to adulterate the oil of roses, and is obtained from a plant of the genus *Andropogon*.

**Gérant** [Fr.], the responsible manager of a joint-stock association, or newspaper establishment; the acting partner.

**Gerle**, a wine measure of Switzerland, about 16 gallons.

**Gerloantico**, a fine, rare, and rich flesh-colored Italian marble, used for statuary purposes.

**German**, a fire-insurance Co., located in Baltimore, Md., organized in 1865. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$500,000; net surplus, \$160,756.74; risks in force, \$29,142,000; premiums, \$142,671.58; premiums received since the organization of the Co., \$1,306,783; losses paid, \$395,225; cash dividends paid to stockholders, \$243,000.

**German-American**, a fire-insurance Co., located in New York City, organized in 1872. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$1,000,000; net surplus, \$815,048.54; risks in force, \$118,670,207; premiums, \$1,081,704.07; premiums received since the organization of the Co., \$6,472,805.97; losses paid, \$2,669,126.17; cash dividends paid to stockholders, \$740,000.

**German-Clock**, a small, cheap hanging-clock, largely made in Germany.

**Germania**, a fire-insurance Co., located in New York city, organized in 1859. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$500,000; net surplus, \$754,423.72; risks in force, \$73,333,025; premiums, \$727,867.06; premiums received since the organization of the Co., \$10,783,104.02; losses paid, \$5,019,930.72; cash dividends paid to stockholders, \$1,046,000.

**German-Paste**, a food sold for certain kinds of caged birds, as blackbirds, thrushes, larks, etc., made of pea-meal, hemp-seed, maw-seed, lard, and honey or treacle.

**German-Sausage**, a polony; a bladder or cleaned gut stuffed with meat partly cooked.

**German-Silver**, **Albata**, **Argentan**, **Electrum**, **Nickel-Silver**, **Tutenag**, **Virginian Plate**, **White Copper**, a well-known alloy, the finer varieties of which nearly equal silver in whiteness and susceptibility of receiving a high polish, whilst they surpass it in hardness and durability. The manufacture of nickel or German silver has acquired great importance in this country, and has almost superseded silver-plate. The graceful patterns which it is often made to assume in the hands of the accomplished artist cannot fail to attract the admiration of the beholders in the best stores of our large cities. The following formulæ are from the highest authorities, or are the results of actual analysis of the finest commercial samples:—

1. Copper, 50 parts; nickel, 20 parts; zinc, 30 parts. Very malleable, and takes a high polish. — 2. Copper, 50 parts; nickel, 26 parts; zinc, 24 parts. Closely resembles silver; an excellent sample. — 3. Copper and zinc, of each 41 parts; nickel, 18 parts. Rather brittle. — 4. (M. Gersdorff.) Copper, 50 parts; nickel and zinc, of each 25 parts. Very white and malleable, and takes a high polish. Recommended as a gen-

eral substitute for silver.—5. (Gersdorff.) Copper, 60 parts; nickel and zinc, of each 20 parts. For castings, as bells, candlesticks, etc.—6. (Gersdorff.) Copper, 60 parts; nickel, 25 parts; zinc, 20 parts. For rolling and wire. Very tough and malleable.—7. (Sample made from the ore of Hilburghausen.) Copper, 40½ parts; nickel, 31½ parts; iron, 2½ parts; zinc, 25½ parts. Equal to the best Chinese sample.—8. (Pelouze.) Copper and nickel, equal parts. Recommended by M. Pelouze as superior to any of the alloys containing zinc.—9. (Pelouze.) Copper, 2 parts; nickel, 1 part. Not so white as the last, but more malleable.—10. (White copper from China.) Copper, 41 parts; nickel, 32 parts; iron, 2½ parts; zinc, 24½ parts. Silvery white, takes a high polish, very soursour, malleable both cold and at a dull-red heat, and may be rolled into leaves or formed into wire.—11. (White metal spoon, sold as "German plate.") Copper, 55 parts; nickel, 24 parts; zinc, 16 parts; tin, 3 parts; iron, 2 parts.—The union of the metals in the above formulæ is effected by heat, with the usual precautions. When iron is ordered, it is generally added under the form of "tin plate."

*Imp. duty:* Unmanufactured, 35 per cent; manufactures of, 40 per cent.

**German-Steel**, a metal made of pig or white-plate iron in forges where charcoal is used for fuel. The ore from which it is obtained is bog-iron or the sparry carbonate.

**German-Text**, a name for an ornamental printing-type.

**German-Tinder**. See AGARIC.

**Germany**, a large and powerful empire of Central Europe, lying between lat. 47° 18' and 55° 20' N., lon. 5° 50' and 22° 50' E. It is bounded N. by Denmark and the Baltic; E. by Russia and Austria; S. by Austria and Switzerland; and W. by France, Luxemburg, Belgium, Holland, and the North Sea, or German Ocean. The Constitution of the Empire bears date April 16, 1871. By its terms, all the states of G. "form an eternal union for the protection of the realm and the care of the welfare of the German people" (*schliessen einen ewigen Bund zum Schutze des Bundesgebiets, und zur Pflege der Wohlfahrt des deutschen Volkes*). The supreme direction of the military and political affairs of the Empire is vested in the king of Prussia, who, as such, bears the title of Deutscher Kaiser. According to Art. 11 of the constitution, (hat das Reich völkerrechtlich zu vertreten), and can declare war, if defensive, and make peace, as well as enter into treaties with other nations, and appoint and receive ambassadors. To declare war, if not merely defensive, the Kaiser must have the consent of the Bundesrath, or Federal Council, in which body, together with the Reichstag, or Diet of the Realm, are vested the legislative functions of the Empire. The Bundesrath represents the individual states of G., and the Reichstag the German nation. The members of the Bundesrath, 59 in number, are appointed by the governments of the individual states for each session, while the members of the Reichstag, 397 in number, are elected by universal suffrage and ballot, for the term of three years. Both the Bundesrath and the Reichstag meet in annual session, convoked by the Kaiser. The Kaiser has the right to prorogue and dissolve the Reichstag, but the prorogation must not exceed sixty days; while in case of dissolution new elections have to take place within sixty days, and a new session has to open within ninety days. All laws for the Empire must receive the votes of an absolute majority of the Bundesrath and the Reichstag. The Bundesrath is presided over by the Reichskanzler, or Chancellor of the Empire, and the President of the Reichstag is elected by the deputies. The laws of the Empire, passed by the Bundesrath and the Reichstag, to take effect must receive the assent of the Kaiser, and be countersigned when promulgated by the Chancellor of the Empire.

The latter, in his capacity as President of the Bundesrath, has the right to be present at the deliberations of the Reichstag.—Berlin (for which see PRUSSIA) is the capital of the Empire.

The following table gives the area and population of the 25 states of G. in the order of their areas, and of the Reichsland of Alsace-Lorraine, together with the average density of pop. of each, as returned by the census taken Dec. 1, 1875.

STATES OF THE EMPIRE.	Area in sq. miles.	Population, Dec. 1, 1875.	Density of population per sq. m.
1. Prussia.....	137,066	25,742,404	188
2. Bavaria.....	29,292	5,022,390	170
3. Württemberg.....	7,675	1,881,505	245
4. Saxony.....	6,777	2,760,586	407
5. Baden.....	5,851	1,507,179	257
6. Mecklenburg-Schwerin..	4,884	553,785	114
7. Hesse.....	2,866	884,218	307
8. Oldenburg.....	2,417	319,314	132
9. Brunswick.....	1,556	327,493	214
10. Saxe-Weimar.....	1,421	292,933	206
11. Mecklenburg-Strelitz..	997	95,673	95
12. Saxe-Meiningen.....	933	194,494	208
13. Anhalt.....	869	213,595	245
14. Saxe-Coburg.....	816	182,593	223
15. Saxe-Altenburg.....	509	145,844	286
16. Waldeck.....	466	54,743	117
17. Lippe.....	445	112,452	256
18. Schwarzburg-Rudolstadt.....	340	76,676	225
19. Schwarzburg-Sondershausen.....	318	67,480	212
20. Reuss-Schleiz.....	297	92,375	311
21. Schaumburg-Lippe.....	212	33,133	155
22. Reuss-Greiz.....	148	46,985	317
23. Hamburg.....	148	388,618	2,625
24. Lübeck.....	127	56,912	448
25. Bremen.....	106	142,200	1,345
Reichsland of Alsace-Lorraine.....	5,580	1,531,804	227
Total.....	212,091	42,727,360	201

At the census of Dec. 1, 1875, the number of males was 20,986,701, and the number of females 21,740,659, being an excess of 753,958 females over males in the total population of the Empire.—Of the total pop., there are 25,580,615 Protestants, 14,868,608 Roman Catholics, 512,160 Israelites, and about 100,000 of other religious persuasions.—The number of Germans in the surrounding States (Austria, Switzerland, etc.), may be estimated at about 13,000,000, giving a total of 54,000,000 as German-speaking people.

Emigration, which formerly assumed larger proportions in Germany than in any other country of Europe, has been gradually declining in recent years. It reached its highest point in 1854, when over a quarter of a million of persons left the country, then sank gradually till 1862, in which year the number fell to 27,529, and from thence rose again, with fluctuation, till the year 1872, when there were 155,595 emigrants to the U. States alone. In 1873 the total emigration fell to 130,937; in 1874 to 75,502; in 1875 to 56,289; in 1876 to 37,803; and in 1877 to 21,964. From 1875 to 1877, the number of immigrants was nearly as large as that of emigrants. During the 22 years from 1846 to 1877, the total emigration to the U. States, which absorbs the best classes of emigrants, numbered 2,635,430 individuals. It is calculated that each presented, on the average, a money value of 200 marks, or \$50, so that the total loss by this emigration amounted to \$133,427,150. The gradually decreasing stream of emigration mainly flowed through Hamburg and Bremen.

By deviation to the general arrangement of this

work, and considering that the formerly independent states which now constitute the German Empire have still retained a shade of individuality, we have thought proper to consider each of these states in a separate article, under its own name. The following, therefore, is only a general outline of the German country, to which are added such information and commercial statistics as do not appear elsewhere.

The surface of *G.* is much diversified. Its S. E. and E. parts are occupied by numerous ranges of hills and mountains, sometimes separated only by narrow valleys, and elsewhere forming large elevated plains, while the N. portion of the country sinks into a wide sandy moorish plain, but little raised above the level of the sea. The mountains, which may be considered as a N. branch of the great Alpine system of Europe, bear no comparison with the Alps in point of height, for the loftiest summits are not more than 5,000 ft. high; but they occupy a great space, and diverge in so many various directions through the country that it is difficult to trace them without the aid of a map. The *Fichtelgebirge*, however, in the N. part of Bavaria, may be considered as the centre and

through Lower Silesia, Lusatia, Brandenburg, Pomerania, Mecklenburg, Holstein, Hanover, and the lower part of Westphalia. To the W. of the Elbe the flat country is almost entirely destitute of trees, and presents only a succession of level tracts, covered with heath and juniper, and of moors consisting chiefly of deep beds of turf intersected by rivers which flow in depressions from 100 to 200 feet below the general level of the plains. To the E. of the Elbe the country is more sandy, but the sandy tracts are covered with pines, and interspersed with fertile spaces of sometimes considerable extent. The beds of the rivers also are generally wider and less deep than in the western part of the plain. Through the N. part of this plain a higher tract may be traced from W. to E., from Oldesloe in Holstein to Schwedt on the Oder, about 70 m. from the sea. Eastward of the Oder it continues for some distance due E., then gradually approaches the sea, terminating on the banks of the Niemen near Grodno. It seems to have formed at one time the shore of the sea, and it is on its N. sides that are found those numerous erratic blocks or boulders that have attracted so much of the attention of geologists. Though it does not rise into hills, it forms the watershed between a number of small streams that run direct to the Baltic, and others that run southward to the Elbe, the Oder, and the Vistula.

The coal-measures are widely distributed in many parts of *G.*, as Saxony, Silicia, Rhenish Bavaria, and Rhenish Prussia.

Fig. 229. — FRANKFORT-ON-THE-MAIN.

nucleus of the mountains in Central *G.*; and from it branch, in four directions, the ranges composing the watershed that divides the rivers of the Black Sea from the Baltic and the German Ocean. 1. The *Erzgebirge*, diverging N. E., forms the boundary between Saxony and Bohemia, and has its scarped side S. towards the Eger. Its E. continuations, called the *Sudetengebirge*, join the Carpathian ridge near the sources of the Oder and Vistula. 2. The *Bohemian Forest* (*Böhmerwald*) range separates Bohemia from Bavaria. It runs S. E. about 150 m., and taking a N. E. turn joins the *Sudetengebirge* near the sources of the Murch. in lon. 16° 40' E. 3. The *Swabian Alps* are a low range branching off S. W. from the central point, and forming the watershed between the affluents of the Rhine and those of the Danube. S. they join the *Black Forest* range, the connection of which with the Alps is effected by a low chain skirting the Lake of Constance, and joining the main ridge at Mt. Septimer. 4. The *Thuringian* range runs N. W. from the *Fichtelgebirge*, and after a course of 50 m. divides into two chains, one running N. into Hanover, and forming the *Hartz* chain, the other running W. under various names, nearly as far as the Rhine, and separating its waters from those of the Weser and its tributaries. The banks of the Moselle are remarkable for their varied scenery, and the valley of the Rhine unites the grandeur of a fine landscape with the appearance of a highly fertile country. To the northward of the hilly region the country sinks into plains, which fall very gradually from an elevation of about 300 feet at the foot of the hills to the level of the sea. These plains extend

*G.* is now the largest producer of coal in continental Europe. The product of coal and lignite for the 10 years from 1868 to 1877, in tons of 2,200 lbs. was as follows:

Coal.					
	Tons.		Tons.		
1868	25,704,758	1873	36,392,280		
1869	23,774,368	1874	35,918,614		
1870	26,397,770	1875	37,496,368		
1871	29,373,272	1876	38,454,428		
1872	33,306,418	1877	37,576,071		

Lignite.					
	Tons.		Tons.		
1868	7,174,365	1873	9,752,914		
1869	7,569,545	1874	10,739,532		
1870	7,095,234	1875	10,367,686		
1871	8,482,838	1876	11,096,034		
1872	9,018,048	1877	10,720,296		

Of the above totals 89 per cent was sent out from the pits in Prussia. In 1877 the city of Berlin used 1,110,216 tons of coal of all kinds.

No part of Europe yields a greater variety or abundance of mineral productions, and in no part of the world are the mines worked with so much skill or so much economy. Precious stones are discovered in many parts; rock crystal, amethysts, topazes, are found in Bavaria; rock salt and Glauber salts in

various parts; and abundance of the earths calculated for making earthenware, from the coarsest description to the finest porcelain. Gold is procured, though in very small quantities, by washing, in Silesia. Silver and cinnabar are raised from the mines of the Erzgebirge in Saxony. Iron, copper, tin, lead, calamine, bismuth, cobalt, nickel, titanium, arsenic, and almost every other mineral, is more or less raised from the mines. The abundance of mineral substances everywhere scattered, and which it would be difficult to enumerate, has promoted the study of mineralogy, and given birth to the school of Freyburg, whence the pupils of Werner carried the science to every part of the world. — *Soil.* The soil is generally productive. The plains in the N. have indeed much arid sandy land; but nature has provided some rich and fruitful soils along the borders of the rivers, where the most abundant harvests are gathered. The S. has also on its mountains much barren or slightly productive land; but the beautiful valleys and plains among the hills rival in fertility the best alluvial lands on the banks of the northern rivers. In general the soil in the N. is heavy, and in the S. light: the former most adapted for corn, and the latter for wines. The best soil is in the middle, between the mountains and the sandy plains. In Silesia, Franconia, Saxony, and on the Rhine, the proportion of good soil is much greater than in the N. or the S. — *Rivers.* Germany has five large rivers which pass through it to the sea, and in their course receive about 500 smaller streams, about 60 of which are navigable, either naturally or by means of artificial improvement. These are the Danube, Rhine, Weser, Elbe, Oder, Etsch or Adige, and Ems, the first two of which will be found described under their own names. The Weser is formed by the juncture, at Minden, of the Werra and Fulda, which rise in the *Rhonegebirge*; its course is N. by W. till the juncture of the Aller, at which point it turns N. E., and falls into the German Ocean about 40 m. below Bremen. The Elbe rises on the N. side of the plateau of Bohemia, which, after receiving the Moldau and the Eger, it leaves at Schandau, and enters the great N. W. plain of G., which it traverses to the German Ocean; its chief affluents from the S. are the Mulda and Saale from the Erzgebirge, and its principal N. tributary is the Havel. The Oder rises on the N. side of the Carpathian range, near its W. termination, and after a general N. W. course, and receiving many affluents, falls through the Great Haffe into the Baltic Sea. — *Lakes.* The chief of the German lakes is the *Boden See*, or Lake of Constance, on the borders of Switzerland. Along the S. shores of the Baltic or East Sea there is a number of lakes, which form the western portion of an innumerable series, extending through Prussia into Russia and Finland, and occupying comparatively higher ground than the adjoining plains and river channels. Some of these are of considerable extent, as the lake of Schwerin in Mecklenburg and the Spirding See in East Prussia, the latter, however, beyond the political limits of G. At the E. base of the Hartz are the salt and the sweet lakes (*Salzige and Susse Seen*), and to the N. of Minden, to the E. of the Weser, is a considerable sheet of water called the *Steinhuder Meer*; and to the west of the Weser is a smaller lake called the *Dummer See*. — *Climate.* The climate of G. is very uniform in respect of the degrees of cold or heat experienced in its different regions; for though there is a difference of 8° of latitude between its S. and N. borders, that difference is compensated by the different elevations of the country, the northern part being lowland on the sea, while the midland and S. regions rise to a considerable elevation. This is indicated by the following table of places from north to south.

Places.	Latitudes.	Elevation above the sea in feet.	(Fahrenheit). Mean temperature of the climate.		
			Year.	Winter.	Summer.
Stralsund ..	54° 19'	51	47	30	63
Berlin ....	52° 30'	140	48	31	64

Ratisbon ..	49° 1'	1,249	48	31	64
Munich ...	48° 10'	1,733	48	34	65

*Agriculture.* In the intelligent practice of agriculture G. is not behind the most advanced of the other countries of Europe. Mecklenburg, in particular, and Holstein are distinguished for their excellent husbandry; and in Hanover, Brunswick, Bohemia, Saxony, and some parts of Prussia and Austria, it is scarcely inferior. Generally speaking, agriculture is the principal occupation of the Germans, particularly in Bavaria, Württemberg, Baden, Hesse, Nassau, Hanover, Brunswick, Oldenburg, Prussia, Anhalt, Holstein, and Mecklenburg; while in the Saxon duchies, Schwartzburg, and Reuss, some districts of Prussia, Bohemia, and the kingdom of Saxony, manufactures employ at least an equal, and in some cases even a greater, number of the people. The greatest contrast in respect of agriculture is to be seen in Mecklenburg and Württemberg. In the former, farming is conducted on a large scale: in the latter, as well as in other provinces, the land is divided into small parcels cultivated by small proprietors or tenants, who

follow ancestral usages, and are unprovided with means to make any improvements, by draining or otherwise. In the former, the *Schlagwirtschaft* prevails, according to which one immense field is covered with wheat, while another is covered with oats, a third with clover, a fourth is being ploughed and harrowed, and a fifth is feeding herds of cattle, the common size of farms being so much as 500,000 square *ruthen*, or almost 2,000 acres: in the latter, everything is grown checkerwise, in small patches, more like gardening than farming, the usual size of Württemberg farms being only from 5 to 20 square *ruthen*, or from  $\frac{1}{16}$  to  $\frac{1}{10}$  of an acre. — G. is suitable for the cultivation of all the kinds of useful plants that belong to the temperate zones; and, owing to the equality of the climate, they are spread over all the country. Maize, however, is principally raised in the S.; wheat in the S. and W.; buckwheat in the N.; millet in the S. E.; rape-seed, poppy, anise, and cummin, in the central and N. W. districts. Flax and hemp, madder, wool, and saffron are cultivated more in the S. and central region than in the N. Tobacco is extensively raised (even for exportation to other tobacco-growing countries) on the upper Rhine, the Werra and Oder, and in Brandenburg. Excellent hops are furnished by Bavaria and Brunswick. Beets are raised in enormous quantities for the manufacture of sugar, and their cultivation has almost entirely superseded the grain-culture in the Prussian prov. of Saxony, Anhalt, Hesse-Darmstadt, and S. Bavaria. Chicory, as a substitute for coffee, is raised in the country between the Elbe and Weser rivers. In garden culture Württemberg, Bavaria, Hesse, and the Saxon duchies hold the highest rank. The fruit raised on the banks of the Rhine and Neckar, in Saxony and N. W. Bavaria, is of the very best quality to be found anywhere. Peaches and figs ripen only in localities protected from the cold. The apples of Saxony are of the choicest kind, and are exported to Russia in large quantities. Marron chestnuts, almonds, etc., are raised in the S. W. states. Great attention is paid to the improvement of fruit. The culture of the vine extends to lat. 51° 30' (see GERMANY, WINES OF). The culture of forests is conducted upon a more scientific basis than in any other country. Having in former times thoughtlessly destroyed their forests, many German states have been compelled to replant them in order to satisfy the wants of agriculture and industry. In many states the forests mostly belong to government, and are as carefully kept as gardens; but even private owners are prohibited by law from wasting their forests without regard to the public good. The most extensive forests are found in central and southern G. and in the eastern provinces of Prussia. The entire superficies of woodland in G. is 52,339 sq. m., of which Prussia has 31,423, Bavaria 9,376, and Württemberg about 2,236.

*Manufactures.* In many branches of manufacturing industry G. has reached a high degree of excellence. German linen is known to the whole world; and the linens of Bielefeld and Silesia in particular are equally valued in America as in Europe. The introduction of cotton, however, has tended greatly to lessen the cultivation of flax, which was formerly a principal staple of agricultural industry, and the linen manufacture has suffered in consequence. With the improvement of the breeds of sheep, the woollen manufacture has made great progress, the German cloth being now not merely equal but even superior in quality to the cloths of England and Belgium. The chief seats of the cloth manufacture are in Brandenburg, Saxony, and the Prussian Rhinish provinces, from which it is exported to all parts of the world. The cotton manufacture has recently assumed very large proportions, the number of spindles in 1879 being estimated at 6,000,000. The German silk fabrics equal the English in quality. The principal silk manuf. are in the Prussian cities of Berlin, Elberfeld, and Crefeld, and in Saxony. The export of silk fabrics from G. is nearly equal to the domestic consumption. Works in metal, especially iron and steel, are produced in great perfection, and large quantities in Rhinish Prussia, Westphalia, and the district of the Hartz; brass work, in Rhinish Prussia, Bavaria, and Brandenburg; gold and silver work in Augsburg and Berlin. Pottery and glass-making have reached a high degree of perfection: the porcelain of Vienna, Berlin, and Meissen, is much in request, on account not only of the fineness of its material, but also for the tasteful elegance of its forms and ornaments. Bohemian glass is to be met with in all parts of the world. The manufacture of leather is particularly extensive in Rhinish Prussia; of soap, tallow wares, and wax, in many places. Paper-making is carried on to a great extent, and of late has been very much improved in quality. Sugar-refining is carried on in Hamburg, Berlin, Potsdam, and other places; brewing of beer, to a great extent, in Bavaria; and ardent spirits (*Brantwein*), to a still greater extent in the N. Ship-building and the connected trades are daily assuming more importance. German industry is much distinguished in the making of mathematical, physical, surgical, and musical instruments: the chief seats of these branches of trade being Munich, Berlin, and Cassel. German clocks and wooden articles, manufactured in the Tyrol and other mountain provinces, are exported to all parts of the world. The great progress which the Germans have made in manufacturing industry within the last half-century is chiefly the result of extraordinary exertions on the part of the German

governments. In every district exist industrial schools, and in all the chief towns there are schools and institutions for instruction in the higher branches of art, where pupils are trained in both practice and theory at the expense of the government. —The results of an agricultural census taken in 1873 showed that at that date there were in the Empire 3,352,231 horses; 13,315 mules and donkeys; 15,776,702 head of cattle; 24,999,706 sheep; 7,124,088 swine; 2,320,002 goats; and 2,333,484 beehives. The number of families possessing livestock (*viehbesitzende Haushaltungen*) was found to be 5,028,023, and of these there were 2,965,856 devoted partly or wholly to agricultural pursuits.

books. Great wool-markets are likewise held in Berlin, Breslau, Dresden, Magdeburg, Prague, Stettin, etc.

The foreign commerce of *G.* is of considerable importance. The total value of imports in 1877 was \$967,000,000; of exports, \$641,600,000. The three free towns (see BREMEN, HAMBURG, LÜBECK) are the chief gates of commercial intercourse of *G.* with foreign countries. The subjoined tabular statement exhibits the growth of the commercial intercourse between *G.* and the U. States, giving the total value of the imports of American home and foreign produce into the Empire, including the Hanse towns, and the total value of direct exports from there to the U. States, for the 20 years 1859 to 1878:—

YEARS.	Imports from the U. States.		Total imports.	Exports to the U. States.	Total imports and exports
	Domestic.	Foreign.

**Commerce.** The trade and commerce of the Empire are under the administration and guidance of special laws and rules, emanating from the *Zollverein*, or Customs' League, which embraces the whole of the states of *G.*, with the exception of the two cities of Hamburg and Bremen. The privilege of Hamburg and Bremen to remain "free ports," conceded in 1868, was ratified in the Imperial Constitution of April 16, 1871, the 31st article of which enacts that the two Hanse towns shall remain "outside the common line of customs until they themselves demand admittance." The administration of the *Zollverein* is at Berlin. There was, previous to the year 1871, a twofold representation of the *Zollverein*, that of governments, in the *Zollverein* Council, and that of populations, in the *Zollverein* Parliament, the members of which latter body were elected in the same manner as the deputies to the North German Federal diet, and met in annual session at the beginning of the year. Under the constitution of April 16, 1871, the functions of the *Zollverein* Parliament merged in the Reichstag of the Empire. The *Zollverein* Council has three committees sitting permanently, namely, for finance, for taxes and customs, and for trade. All the receipts of the *Zollverein* are paid into a common exchequer, and distributed, *pro rata* of population, among the states of the Empire. The chief sources of revenue are customs duties, mainly on imports, and taxes upon spirits, wine, sugar manufactured from beet-roots, and tobacco. By the *Zollverein* free trade was established among all its members, while a high tariff protected their industry against foreign competition. Under this system *G.* has rapidly progressed, and from an exporter of raw products of the soil, as it was 50 years ago, it has become one of the principal exporters of an endless variety of industrial products, and importer of raw materials. A new tariff was introduced in 1879, which greatly increases the duties on imports, for which see TARIFFS in the Appendix at the end of this book. The principal seats of the inland trade are Berlin, Breslau, Cologne, Magdeburg, Frankfurt-on-the-Oder, Naumburg, Posen, Traustadt, Aachen, Coblenz, Elberfeld, Erfurt, Münster, Minden, and others; in Prussia; Leipzig, in Saxony; Munich, Augsburg, and Nurnberg, in Bavaria; Frankfurt-on-the-Main, Cassel, Brunswick, Hanover, Mentz, etc. But of all these places three hold the first rank: Augsburg, for the S. W.; Frankfurt-on-the-Main, for the N. W.; and Leipzig, for the N. E. Large fairs are held twice or thrice a year in Leipzig, the two Frankfurts, Brunswick, and other places; but it is only in those named that these fairs are of much importance. Those of Leipzig are celebrated for the sale and exchange of

The two following tables give the declared value of the principal articles of American produce and manufacture imported into *G.*, and of the principal articles of German produce and manufacture exported to the U. States, in the year 1878:—

Total	45,261	6,725,819	9,576	3,770,632

On January 1, 1878, the total length of the railroads of the Empire completed and open for public traffic (in kilometres) were as follows:—

STATES.	State roads.	Private roads under State ad- minis- tration.	Private roads.	Total.
Prussia	4,775.42	3,225.05	9,386.07	17,886.54
Bavaria	3,696.42	272.46	467.42	4,436.30
Saxony	1,994.89	37.54	273.75	1,976.18
Württemberg	1,223.80	..	16.50	1,240.30
Baden	1,048.75	124.0	6.78	1,179.53
Hesse	287.36	..	423.94	721.30
Oldenburg	254.33	33.49	46.94	334.76
Mecklenburg	80.0	..	411.3	491.3
Brunswick	21.2	..	37.1	..
Other States	155.07	56.0	871.95	1,083.02
Alsace-Lorraine	1,062.57	..	10.9	1,073.47
Total	14,181.01	3,748.54	12,372.65	30,302.20
English miles	..	..	..	18,957.47

The total number of telegraphic despatches in the year 1877 was 10,649,994, of which 7,172,124 were inland, and 3,477,870 foreign. The length of telegraph lines in the Empire in 1878 was 38,793 kilometres (or 24,317 miles), and of telegraph wires 142,000 kilometres (or 88,750 miles). The total receipts of 1877 amounted to 10,258,529 marks, or \$2,564,000, and the expenditure to 15,958,543 marks, or \$3,989,635. There were 4,532 telegraph stations in 1878.

The Imperial post-office carried 516,407,730 letters, 78,586,580 post-cards, 7,523,180 patterns, 92,867,490 stamped wrappers, and 310,421,781 newspapers, in the year 1877. The total receipts of the post-office in 1877 amounted to 116,967,739 marks, or \$29,241,935, and the total expenditure to 169,414,845 marks, or \$27,353,710, leaving a surplus of 7,552,894 marks, or \$1,888,225.

*Finances.* The common expenditure of the Empire is defrayed, according to Art. 70 of the Constitution, from the revenues arising from customs, certain branches of excise, the profits of the post, and telegraphs. Should the receipts from these various sources of income not be sufficient to cover the expenditure, the individual states of Germany may be assessed to make up the deficit, each state being made contributory in proportion to its population. The common expenditure is to be voted, "as a rule" (*in der Regel*) only for one year; but also for any longer term "in special cases" (*in besonderen Fällen*). The financial year, formerly coeval with the calendar year, was made to run from the 1st of April to the 31st of March in 1877. The budget accounts of the Empire distinguish between ordinary or "continual" (*fortdauernde*) expenditure, and extraordinary, or "for once" (*einmalige*) disbursements. The estimated total ordinary, or "continual" expenditure for the financial year ending March 31, 1879, was distributed as follows:—

	Marks
Chancellor of the Empire	104,980
Chancery of the Empire	4,259,253
Imperial Diet	322,000
Foreign Office	6,104,655
Administration of the Imperial army	322,518,283
Administration of the navy	24,110,520
Interest of the debt of the Empire	6,781,500
Chamber of Accounts	450,510
Imperial Chancery for Alsace-Lorraine	171,790
Railroad Office of the Empire	272,750
General pension funds	17,553,205
Empire invalid funds	32,053,157
Administration of justice	806,182

Total ordinary expenditure..... 415,508,755

The extraordinary expenditures were thus estimated:—

	Marks.
Chancellor and chancery	2,530,000
Imperial Diet	30,000
Foreign Office	527,000
Imperial Post and Telegraphs	13,299,345
Army of the Empire	27,378,540
Administration of the navy	31,580,165
Chamber of Accounts	10,000
Railroads of the Empire	10,102,340
Mint	22,700,000
Expenditures in remission of war taxes, France	9,965,325
Court of Imperial Judicature	35,000

Total extraordinary expenditure..... 120,987,715

Ordinary expenditure..... 415,508,755

Total expenditure..... 536,496,470

\$127,600,149 86

The receipts for the same year embraced the following branches of Imperial revenue:—

	Marks.
1. Customs and excise duties.....	250,326,840
2. Stamp duties.....	6,453,100
3. Profits of posts and telegraphs.....	15,288,408
4. State railroads in Alsace-Lorraine.....	11,356,000
5. Imperial Bank and other receipts.....	2,010,000
6. Receipts of various descriptions.....	7,495,522
7. From the Imperial funds for invalids.....	32,053,152
8. Surplus of former years.....	34,663
9. Profits from the coining of Imperial money..	100,000
10. Interest of Imperial funds.....	7,324,208
11. Extraordinary receipts.....	116,535,056
12. Contributions of states to revenue.....	87,145,516
13. Administration of the Imperial printing-office	174,330

Total..... 536,496,800  
\$127,686,238.40

The contribution of the principal states of the Empire to the revenue for the year 1878-79 was calculated as follows: Prussia, 41,494,909 marks; Bavaria, 19,682,751 marks; Württemberg, 6,806,586 marks; Baden, 4,835,566 marks; Saxony, 4,575,727 marks; and the Reichsland Alsace-Lorraine, 3,060,410 marks. In the budget of the Empire the sums received from France as war indemnity were not entered, but placed to a separate account. Of the war indemnity, agreed upon by Treaty of Feb.

Fig. 230 — TOWN-HALL, DANTZIC.

26, 1871, amounting to 5 milliards of francs, or \$1,000,000,000 *G* had received the total at the end of September, 1873. Besides this treaty indemnity, *G* received a tribute of \$30,000,000 from the city of Paris, and levied contributions in some of the French departments, the total sum paid into the Imperial exchequer amounting, inclusive of interest, to about \$1,100,000,000. Of this sum nearly one half was portioned out among the 25 States of the German Empire. Of the other half, in accordance with various laws passed by the Reichsrath, \$62,500,000 were paid to France for the Alsace-Lorraine railways, and \$39,000,000 for the fortresses in the Reichsland.—The German Empire, as such, had no public debt at the time of its re-establishment, in 1871, but one has been created in recent years. At the end of June, 1878, the total funded debt amounted to 175,216,186 marks, or \$43,804,045, including a loan of 97,484,865 marks, or \$24,371,215, granted by a law of the Reichstag, passed June 14, 1878. The whole debt bears interest at 4 per cent. Besides the funded there exists an unfunded debt, represented by "Reichs-Kassenscheine," or Imperial treasure

bills, now outstanding to the amount of 168,954,850 marks, or \$42,238,715. As a set-off against the debt of the Empire, there exist a variety of invested funds, of a total amount of 865,487,928 marks, or \$216,371,980. These funds comprise an "Invalidentfond" of 562,748,410 marks, or \$140,687,100; a "Festungsbaufond" of 153,976,402 marks, or \$38,494,100; and a "Kriegsschatz" of 120,000,000 marks, or \$30,000,000. The funds were created out of the French war indemnity, and are yearly increasing by interest, notably the last of them, the "Kriegsschatz," or war-treasure, which can be drawn upon only in case of a foreign war, or invasion.

*Banking.* See the names of the principal states.

*Money.* Uniformity of coinage was established by a law of 1872, the unit of account being the *mark* = 23.8 cents, divided into 100 pfennige.

The new coins are as follows:—

*Gold.* The twenty-mark (69½ to 1 lb. of fine gold), ten-mark, and five-mark.

*Silver.* The five-mark (20 to 1 lb. of fine silver), two-mark, one-mark, fifty pfennige (200 to 1 lb. of fine silver), and twenty pfennige.

*Nickel.* Ten pfennige and five pfennige.

*Copper.* Two pfennige and one pfennig.

The old denominations were:—

The <i>Crown</i> , gold coin common to all <i>G</i> , approximate value	= \$6.58.
" <i>Thaler</i> , or 30 <i>Groschen</i> , approximate value	= 0.75.
" <i>Gulden</i> , or florin, of 60 <i>Kreuzer</i> , app. value	= 0.42.
" <i>Mark Current</i> , of Lübeck, approximate value	= 0.31.
" <i>Mark Banco</i> , of Hamburg, approximate value	= 0.37.
" <i>Reichs Thaler</i> , of Bremen, approximate value	= 0.33.

*Weights and Measures.* The French metrical system has been adopted, and made compulsory from Jan. 1, 1872. The following are the principal weights and measures used in commerce:—

The <i>Gramme</i>	= 15.434 grains troy.
" <i>Kilogramme</i> of 2 <i>Pfund</i>	= 2.205 lbs. avoirdupois.
" <i>Centner</i> of 50 <i>Kilogramme</i>	= 110 "
" <i>Quintal</i> of 2 <i>Centner</i>	= 220 "
" <i>Tonne</i> of 20 <i>Centner</i>	= 2200 "
" <i>Liter</i> , Mass	= 1.76 Imperial pints.
" <i>Meter</i> , Stab	= 3.28 feet or 39.37 inches.
" <i>Kilometer</i>	= 1093 yards or nearly 5
" <i>Hektar</i>	= 2.47 acres [furlongs.
" <i>Quadrat</i> , or <i>Square Kilometer</i>	= 247 acres, or 2½ sq. k. to 1 sq. mile.

*Seaports.*—Besides Hamburg, Bremen, and Lübeck (for which see their respective names), the following are the principal commercial and military seaports of *G*.—

*Dantzic*, a strongly fortified city, and one of the principal emporiums of the north of Europe, in West Prussia, 223 mi. N. E. of Berlin, in lat. 54° 20' 48" N., lon. 18° 38' E. It is situated on the left or W. bank of the Vistula, about 4 m. from its embouchure. There is a harbor in the town, but the principal port is at *Menfährwasser*, at the mouth of the river. The town is traversed by the small river *Motlau*, which has been rendered navigable for vessels drawing 8 or 9 feet of water. The road or bay of Dantzic is covered on the W. side by a long, narrow, low, sandy tongue of land, extending from *Keserhoff Point* (on which is a lighthouse), in lat 54° 50', lon. 8° 23' 15", upwards of 20 m. in an E. by S. direction, having the small town of *Heela*, or *Heel*, near its termination. A lighthouse, elevated 123 feet above the level of the sea, stands within about ½ mile of the extremity of this point. The flashes of the light, which is a revolving one, succeed each other every ½ minute. There is good anchorage in the roads for ships of any burden; but they are exposed, except immediately under the *Heel*, to the N. and N. E. winds. There are harbor lights at the entrance to the port. All ships entering the Vistula must have to about a mile off the port, and take a pilot on board; and pilots must always be employed in moving ships in the harbor, or in going up and down the river. The usual depth of water at the mouth of the river is from 12 to 13 feet; in the harbor, from 13 to 14 feet; at the confluence of the *Motlau* with the Vistula, from 9 to 9½ feet; and in town, from 8 to 9 feet. Moles have been erected on both sides of the entrance to the harbor: that on the E. side, which is most exposed, is constructed of granite; the other is partly of stone and partly of timber. Dantzic is a naval station, with docks, magazines, and a marine depot. The manuf. of arms and artillery is carried on to a large extent, and the Imperial and private docks give employment to a great number of workmen. The town is still famous for its amber, beer, brandy, and the liquor known as *Danziger Goldwasser*; and its transit trade is of considerable importance. Its harbors are visited annually by about 2,000 sea-going vessels, besides an immense number of smaller craft employed in river navigation. The chief exports are grain, especially wheat, which comes for the most part from Poland, and timber. The principal imports are herring coal, petroleum, salt, and wine. The annual value of the imports by sea, river, and railroad is about \$37,000,000; that of exports, \$32,000,000. Pop 98,181

**Emden** (formerly *Emdden*), a maritime town in the district of Aurich, prov. of Hanover, situated near the mouth of the Ems, on the Westphalian Railroad, 45 m. W. N. W. of Oldenburg. The town is much intersected by canals, and more than 30 bridges are required to connect its different parts. It has a considerable maritime trade, chiefly in corn, butter, cheese, and wood. Its industries are ship-building, tanning, and the manuf. of paper, cement, and tobacco. Pop. 12,874.

**Kiel**, a strongly fortified seaport, naval station, and arsenal of Prussia, on the N. shore of the prov. of Holstein, at the bottom of a beautiful bay, and at the terminus of a line of railroad from Hamburg. The harbor is safe, and has water sufficient for large ships. Its industries are ship-building, hats, starch, tobacco, and sugar. Pop. 34,816.

**Königsberg**, the capital of East Prussia, in lat.  $54^{\circ} 42' 11''$  N., lon.  $20^{\circ} 29' 15''$  E. It is situated on the Pregel, which flows into the Frische Haff, or Fresh Bay, a large lake having from 10 to 14 feet of water. The bar at the mouth of the Pregel has only from 10 to 11 feet water, so that vessels of more than that draught of water require to be lightened to come up to Königsberg. Pillau, in lat.  $54^{\circ} 33' 39''$  N., lon.  $19^{\circ} 52' 30''$  E., on the N. side of the entrance from the Baltic to the Frische Haff, is properly the port of the town, with which it is connected by railroad. A lighthouse is on a rising ground a little to the south of Pillau, the lantern of which is elevated 95 feet above the level of the sea. The light is fixed and brilliant. The entrance to the harbor is marked by buoys; those on the

soap manufactures. The harbor of Memel is large and safe; but the bar at the mouth of the Currische Haff has seldom more than 17 feet of water, and sometimes not more than 13 or 14 feet; so that ships drawing more than 16 feet of water are frequently obliged to load and unload a part of their cargoes in the roads, where the anchorage is but indifferent, particularly when the wind is N. or N. W. There is a light on the N. E. side of the entrance to Memel harbor, 98 feet above high water, and visible 20 m. off. It is lighted from August 1 to May 15. The outer buoy lies in 6 fathoms of water, about a mile without the lighthouse, which bears from it S. E. by E.  $\frac{1}{2}$  E. The channel thence to the harbor is marked by white buoys on the N. and red on the S. side. Three beacons to the N. of the town, when brought into a line, lead directly into the harbor. Inasmuch, however, as the channel is subject to frequent changes, both in depth and direction, it is always prudent, on arriving at the outer buoy, to heave to for a pilot; but this is not obligatory. Timber forms the principal article of export; for though that of Dantzke is considered better, it is generally cheaper, and almost always more abundant, at Memel. Large quantities of hemp and flax are also exported, as are bristles, hides, linseed, wax, pitch and tar, etc. The exports of grain, especially rye, are sometimes very considerable. The wheat of Lithuania is reckoned the best. All flax and hemp shipped from Memel must be *bracked*, or assorted by sworn selectors. The imports consist principally of salt, herrings, coffee, sugar, spices, dye-woods, tobacco, tea,

Fig. 231. — CASTLE OF HOHENZOLLERN.

larboard side being surmounted by small flags. A Gothic building, 120 feet above the level of the sea, has been erected to serve for a landmark; at a distance it looks like a three-masted ship under sail. There is usually from 15 to 16 feet water between the buoys on entering the harbor; but particular winds occasion material differences in this respect. Being situated on a navigable river of considerable importance, Königsberg has a large command of internal navigation, and is the principal emporium of a large extent of country. Wheat, rye, and other species of grain are the chief articles of export. More tares are shipped here than from any other port in the Baltic. The price of all sorts of grain is usually lower at Königsberg than at the neighboring Prussian ports. Linseed and rape seed, hemp, flax, linens, oil-cake, oil, bristles, refined sugar, etc., are largely exported; with smaller quantities of bones, mats, ashes, feathers, wax, hides and skins, etc. The bristles are the best in the Baltic. The imports are sugar, tea, herrings, iron and steel, coffee, wines, tin and tin plates, dye woods, tobacco, spices, drugs, coals, etc. In 1878 there arrived at Pillau 1,512 vessels of 171,126 tons, of which one third were British. Pop. 122,633.

**Memel**, a commercial town of East Prussia, in lat.  $55^{\circ} 43' 40''$  N., lon.  $21^{\circ} 6' 10''$  E. 74 m. N. E. of Königsberg. It is situated on the N. E. side of the great bay, denominated the *Currische Haff*, near its junction with the Baltic. It is consequently the principal entrepôt of the country traversed by the Niemen, and as such enjoys a pretty extensive commerce. Its principal industries are ship-building, and woollen and

cotton stuffs and yarn, iron, cutlery, wine, etc. This port is open to navigation throughout the year, but the navigation of the river Niemen and adjacent streams, the Currische Haff, etc., closes about the latter end of November, and opens about the middle of April. In 1878, 1,011 ships of 117,446 tons arrived at Memel. Pop. 25,000.

**Rostock**, formerly one of the Hanse towns, and now the principal commercial city of the Grand Duchy of Mecklenburg-Schwerin, on the Warnow, about 9 m. above where it falls into the Baltic, lat.  $54^{\circ}$  N., lon.  $12^{\circ} 12'$  E. A large fair for merchandise is annually held at Whitsun-tide; and there are wool fairs at other seasons of the year. The output of Rostock is at Warnemünde, at the mouth of the Warnow. The depth of water at the latter varies from 10½ to 12 feet; but at the end of the west pier it varies from 12 to 14 feet. In the river from Warnemünde up to Rostock there is usually from 8 to 9 feet; so that vessels drawing more than this must be lightened to get up the latter. Rostock has a good harbor and commodious quays. The principal articles of import are refined sugar, coffee, cotton, woollens, iron, hardware, earthenware, hemp, flax, tallow, oil, alum, timber, herrings, fish-oil, wine, brandy, molasses, drugs, rice, rum, groceries, etc. The total value of imports by sea is about \$2,000,000. The exports, whose yearly value is about \$3,000,000, consist chiefly of very good wheat, wool, rags of a superior quality, oil-cake, rape-oil, bones, etc. Pop. 29,432.

**Stettin**, a city of Prussia, and the capital of prov. Pomerania, on the left bank of the Oder, about 36 m. from its en-

trance in the Baltic, in lat.  $53^{\circ} 25' 8''$  N., lon.  $14^{\circ} 34' E$ . It is well built, strongly fortified, and is the seat of an extensive commerce, which it owes mainly to its situation. The Oder, which flows through the centre of the Prussian dominions, is navigable as far as Ratibor, near the extreme S. boundary of Prussian Silesia, and is united by means of canals with the Vistula, the Elbe, the Spree, etc. Stettin is, consequently, the principal emporium of some very extensive and flourishing countries; being not only the port of Frankfort-on-the-Oder, Breslau, etc., but also of Berlin. She is also the centre of an extensive system of railroads communicating with Berlin and the west parts of Germany on the one hand, and on the other with Posen, Bromberg, and Danzig. Hence, at the proper seasons, her wharves are crowded with lighters that bring down the produce of the different countries traversed by the river, and bring back colonial products, and other articles of foreign growth and manufacture. Vessels of considerable burden, or those drawing above 7 or 8 feet of water, load and unload, by means of lighters, at the mouth of the river at *Swinemünde*, the outport of Stettin, on the E. coast of the isle of Usedom, in lat.  $53^{\circ} 55' N.$ , lon.  $14^{\circ} 15' 15'' E$ . Formerly there were not more than 7 feet of water over the bar adjacent to Swinemünde; but the harbor of the latter has been so much improved by the construction of piers and breakwaters, dredging, etc., that it is now the best on the Prussian coast, and admits vessels drawing from 18 to 19 feet of water. A lighthouse has been erected at the extremity of the eastern pier, in  $53^{\circ} 56' N.$  lat., and  $14^{\circ} 17' E.$  lon., visible 10 m. off, and there is another (visible for 21 m.) situated a mile and a half S. of the Mole Light. There are also two light-ships between Swinemünde and Stettin. Stettin is a free port; that is, a port into and from which all sorts of goods may be imported and re-exported free of duty. Pop. 80,972.

**Wilhelmshaven**, the most important of the three German ports of war (the others being Kiel and Danzig), on the North Sea, in the Bay of Jader, near the mouth of the river Elbe. This port was opened by the Emperor Wilhelm I. on the 17th of June, 1869. It is a vast artificial construction of granite, and comprises five separate harbors, with canals, sluices to regulate the tide, and an array of dry docks for ordinary and ironclad vessels. The first harbor is an artificial basin, flanked by granite moles, respectively 4,900 and 9,600 feet long. This basin, called "the entrance," is 700 feet long and 350 wide, and leads to the first sluice, 132 feet long and 66 wide. The next basin, or outer harbor, is 600 feet long and 400 wide; the second sluice, immediately behind, as long and as wide as the first. Then follows a canal 26,000 feet long, varying in width from 260 to 108 feet, and having about half-way another harbor for dredging-steamers and similar craft. This leads to the port proper, consisting of a basin 1,200 feet long and 750 wide, with a smaller basin for boats. At the back of the principal harbor there are two large ship-yards.

**Wismar**, the second seaport town of Mecklenburg-Schwerin, at the confluence of the river Stör with the sea, in lat.  $53^{\circ} 53' 5'' N.$ , lon.  $11^{\circ} 27' 7'' E$ . The harbor is commodious and safe, being nearly landlocked by the islands of Poel and Walfisch. Close to the town there is from 8 to 8½ feet water; in the inner roads there is from 12 to 13 feet; and in the outer, from 16 to 20 feet. The articles of import and export are the same at Wismar as at Rostock; but owing to the proximity of Lübeck, from which Wismar is not more than 27 m. distant, her foreign trade is comparatively limited. Pop. 14,316.

**Germany (Wines of).** The Germans have wasted a good deal of idle conjecture on the antiquity of the culture of the vine in their country. While many of their writers ascribe its introduction to the Emperor Probus and his legions, about the year 280, others go up to the Asiatic Bacchus, and pretend that Bacharach, in the vicinity of which so many excellent vineyards are found, derived its name from the deity of wine; a stone still existing in the river which they call "Bacchus's altar." Had the etymology been treated metaphorically in this way, to describe the vine country on the Rhine, and some of its tributary rivers, it would not have been out of place to call it the country of Bacchus. The banks of the Rhine, Moselle, Neckar, and Main are gardens of the vine; nor have the Germans been content with cultivating the banks of rivers alone, but the

higher lands are planted with the greatest success. From Bonn to Coblenz, and from the latter city to Mayence, the country is covered with vineyards. The Johannisberger of "father" Rhine, the Gruenhäuser, or the Braunberger, of the Moselle, and the Hochheimer of the Main, each distinguish and hallow their respective rivers in the eyes of the connoisseur in wine.

Whoever has visited the noble Rhine must have felt sensible of the beauty of its vineyards, covering steep and shore, interlaced with the most romantic ruins, towns ancient and venerable, smiling villages, and the rapid broad German river, reflecting the rich scenery on its banks. From Mentz even to Bonn the vineyards of the Rhine are observed to greater advantage than any similar cultivation in other countries: Erbach, enthroned on its vines; the Rheingau, its Johannisberger on a crescent hill of red soil, adorned with cheering vegetation; Mittelheim, Geisenheim, and Rüdesheim, with its strong, fine-bodied wine, the grapes from which bask on their promontory of

Fig. 232. — THE HEIDELBERG TUN.

rock in the summer sun, and imbibe its generous heat from dawn to setting; then, again, on the other side, Bingen, delightful, sober, majestic, with its terraces of vines, topped by the château of Klopp. The river and its riches, the corn and fruit which the vicinity produces, all remind the stranger of a second Canaan. The Bingerloch, the ruins, and the never-failing vines scattered among them, like verdant youth revelling amid age and decay, give a picture nowhere else exhibited, uniting to the joyousness of wine the sober tinge of meditative feeling. The hills back the picture, covered with feudal relics or monastic remains, below Asmannshäusen to Lorch, mingled with the purple grape. Bacharach is near, the wine of which is very good, though it is now pronounced second-rate in quality. Landscapes of greater beauty, joined to the luxuriance of fruitful vine-culture, can nowhere be seen. To the north of Coblenz the wines are of little comparative note, though Bodendorf, near Bonn, has been said to produce a Rhenish wine of the second growth, thus far to the north. Either on the Rhine, or on its tributary rivers between Coblenz and Mayence, all the most celebrated wines of Germany are grown.

The grapes which are preferred for general cultivation are the *riesling*, a small white species, harsh in taste, but in hot

seasons furnishing a remarkably excellent wine, having a fine bouquet; the *kleinberger*, a productive species, which ripens easily; and a small Orleans variety. The vintage does not take place until the grapes are perfectly mature; they are then carefully gathered, the bad fruit picked out, and with the stalks put aside. The wine of the pressings is separated, *most vom ersten druck, vom nachdruck*. The more celebrated of these wines are all fermented in casks, and then, after being repeatedly racked, suffered to remain for years in large fuddlers to acquire perfection by time. These huge casks contain each about 350 tuns. The wines mellow best in large vessels; hence the celebrated Heidelberg tun, 31 feet long by 21 feet high, and holding 150 fuddlers, or 600 hogsheads; the second of these was built at Heidelberg in 1613. That which preceded it held but 132 fuddlers. This tun (Fig. 232) is decorated with all kinds of fantastical ornaments. Tübingen, Gruningen, and Königstein (the last 3,709 hogsheads) could all boast of their enormous tuns, in which the white wines of the country were thought to mellow better than in casks of less dimensions. These tuns were once kept carefully filled. The Germans always had the reputation of being good drinkers, and of taking care of the "liquor they loved."

The wines German are a distinct class in character from all other wines. They are generous, dry, finely flavored, and endure age beyond example. Their average about 12.08 per cent of alcohol. They have been supposed to turn acid sooner than other wines, though the reverse is a remarkable fact. On this subject a writer observes, with respect to Moselle, and the same will hold good with other wines of Rhenish character, that, "the country which borders on the Moselle produces abundance of grapes, and some of the wines have an agreeable flavor, especially the vintage of *Braunberg*. This highly flavored wine is a fashionable beverage at the first tables in London, and, when cited in summer, nothing can be more grateful. Some of it has the flavor of the Frontignan grape, without its sweetness. This wine has a singular quality; it is difficult to make it into vinegar. The author accidentally discovered this property by putting a few bottles into a greenhouse, and afterwards into his cellar, for the purpose of using it as vinegar; but the following spring he was surprised to find that no acetous fermentation had taken place. It has been generally supposed in England that the wines of the Rhine and Moselle are more acid than the white wines of France; but if the above experiment may be any criterion of the qualities of the former, it would prove that they are less acid than Sauterne, Barsac, and the Graves; for it is well known that it is necessary to sulphur the casks of these wines to prevent the acetous fermentation taking place."

To proceed northward with the "Rhine wines," following the course of the Main River. The ordinary wines are not worthy of note. The *Liebfrauenmisch* is a well-bodied wine, grown at Worms, and generally fetches a good price. The same may be said of the wines of *Kosterick*, near Mayence, and those from *Mount Scharlachberg* are equally full bodied and well flavored. *Nierstein*, *Oppenheim*, *Laubenheim*, and *Gau-bischeim* are considered to yield first growths, but that of *Deidesheim* is held to be best. The prices vary much, and depend in a great degree upon the age of the wine. New wine may be had from 30 cents the *maas* (a little more than two quarts) to \$1.25; very aged wine from \$2 to \$4.50 the bottle. The Main runs up to Frankfurt close to Mayence, and on its banks the little town of Hochheim stands upon an elevated spot of ground, in the full blaze of the sun. From Hochheim is derived the name of *Hock*, too generally applied in England to all German wines. No trees are seen to obstruct the gulf fire from the sky, which the Germans deem so needful to render their vineyards propitious. The town stands in the midst of vineyards. That which produces the *Hochheimer* of the first growth is about eight acres in extent, and situated on a spot well sheltered from the N. winds. The produce, in a tolerable year, is 12 large casks, which sell for about \$800 each. The whole eastern bank of the Rhine to Lorch, called the Rheingau, has been remarkable centuries past for its wines. It was once the property of the Church. The entire district is one delicious vine-garden. In this favored spot grows the castle, or Schloss-Johannesberger, once the property of the Church, and also of the Prince of Orange. Johannesberg is a town, with its castle (*schloss*), on the right bank of the Rhine below Mentz. The *Johannesberger* takes the lead in wines of the Rhine. The vines are grown over the vaults of the castle, and the quantity of wine produced is very small. The other growths near the same vineyard are excellent, and the vintage of ten years sell for \$200 to \$300 the cask of 30 gallons. *Rudesheim* produces wines of the first Rhine growths; but the *Steinberger*, belonging to the Duke of Nassau, takes rank after the Schloss-Johannesberger among these wines. It has the greatest strength, and yet is one of the most delicate, and even sweetly flavored. The quantity made is small, of the first growth. *Grafenberg*, which was once the property of the Church, produces very choice wine, equal to the *Rudesheim*. *Marcobrunner* is an excellent wine, of a fine flavor, especially when the vintage has taken place in a warm year. The vineyards of *Roth* and *Königsbach* grow excellent wines. Notwithstanding the quality of endurance many of the second-rate growths possess, and a freedom from acidity equal to those

which hold the first place, they are by no means so well known as they ought to be. The excellence of the wine in any particular year always depends more upon the warmth of the season than upon any other cause, and the high price of the wine in corresponding years rises accordingly. The Germans say that the wines of the best body are made on the higher lands, and the worst on the lower; the last requiring the longest keeping to render them mellow for drinking. The wines of 1811, still to be found in the trade, bear a very high character. There is something unaccountable in the extraordinary durability of wines grown so far to the N., when the slightest increase of warmth in a season causes such a difference in the quality of the wine. While strong southern wines suffer from age after a certain period of years in bottle, and begin to deteriorate sensibly, the Rhine wines seem possessed of inextinguishable vitality, and set the greater part of rivalry in keeping at defiance. It is generally found that wines with the lesser proportion of alcohol change sooner than those which are strong. The Rhenish wines, averaging so little in spirit, will endure longer and continue to improve by age as much as the more potent wines of the South, with double their alcoholic strength. On the whole, the wines of Bischoff, Asmannshausen, and Laubenheim are very pleasant wines; those of the most strength are Marcobrunner and Niersteiner, while those of Johannesberg, Glissenheim, and Hochheim give the most perfect delicacy and aroma. The Germans themselves say, *Rhein-wein, fein wein; Necker-wein, bicker wein; Franken-wein, tranken wein, Mosel-wein, maassel wein*. ("Rhine wine is good; Necker pleasant; Frankfurt bad; Moselle innocent.")

The red wines of the Rhine are not of extraordinary quality. The *Asmannshausen* is the best, and resembles some of the growths of France. Near Lintz, at Neuwied, a good wine, called Blisehert, is made. Königsbach, on the left bank of the Rhine, Altenahr, Rech, and Kesseling yield ordinary red growths.

The Moselle wines are secondary to those of the Rhine and Main. The next celebrated is the *Braunberger*. The varieties grown near Treves are numerous. The wines are light, with a good flavor. They will not keep so long as the Rhine wines, but they are abundant and wholesome. Near Treves are grown the wines of *Braunberg*, *Wahlen*, *Graach*, *Zeltingen*, and *Piesport*. The wines of *Kingsport* and *Becherbach* are considered of secondary rank, the wines of *Cassel* and *Vulbach*, near Treves, are thought to be possessed of diuretic properties, and even to cure the gravel. In about five years these wines reach the utmost point of perfection for drinking. They will not keep more than ten or twelve years in prime condition.

The wines called "wines of the Ahr" resemble those of the Moselle, except that they will keep longer.

The *wines of the Neckar* are made from the best French, Hungarian, and even Cyprus vines. The most celebrated are those of *Bessingheim*. They are of a light red color, not deep, and of tolerable flavor and bouquet. Wiesbaden grows some good wines at Schierstein, and Epstein, near Frankfurt. The best wines of Baden are produced at Badenweiler, near Freiburg. At Heidelberg the great tun used to be filled with the wine of that neighborhood, boasted to be a hundred and twenty years old, but it gave the wine no advantage over other Neckar growths. Some good wines are produced near Baden. The red wines of Wange are much esteemed in the country of Bavaria, but they are very ordinary. Wurtzberg grows the Stein and Liesten wines. The first is produced upon a mountain so called, sold very dear, and called *wine of the Holy Spirit* by the Hospital of Wurtzberg, to whom it belongs. The Liesten wines are produced upon Mount St. Nicolas. *Straw wines* are made in Franconia. A *vin de liqueur*, called Calamus, like the sweet wines of Hungary, is made in the territory of Frankfurt, at Aschaffenburg. The best vineyards are those of Bischofsheim. Some wines are made in Saxony, but they are of little worth. Meissen, near Dresden, and Guben produce the best. Naumberg makes some small wines, like the inferior Burgundies.

Most of the so-called Rhine wines sold in this country are of American manufacture. The quantity of German wines imported in the year 1875 was only 204,684 gallons (in casks), valued at \$130,650; and 11,401 dozen bottles, valued at \$85,124. See SPARKLING WINES.

**Geropiga**, a strong, sweet, high-colored compound, consisting of brandy at 25 degrees over proof, coloring and sweetening matters, and unfermented grape-juice, manuf. and used in Portugal to adulterate various kinds of wines, and exported in pipes containing about 100 gallons. This factitious and noxious liquor was formerly largely imported into this country.

**Ghazilieh**, a Turkish mixed fabric, half cotton and half silk, made in pieces about 8 yards long.

**Ghee**, liquid butter made from the milk of buffaloes and clarified; it is an article of very considerable commerce in various parts of India, and

is generally conveyed in dubbars or large bottles made of hide, holding from 10 to 40 gallons each. Ghee will keep sweet a considerable time.

**Gherkin**, a small cucumber used for pickling.

**Ghetchoo**, an Indian name for the *Aponogeton monostachyon*, the roots of which are nearly as good as potatoes, and as much liked by the natives.

**Ghet-kol**, a vernacular name in Bengal for the acrid tuber of *Arum orizense*, used for poultices, applications to snake-bites, and inwardly as a powerful stimulant.

**Gib**, a wood or metal piece or slip, notched or otherwise, in a machine or structure, to hold other parts together, or keep them in place: usually held in its own place by a wedge or key, or by a screw. — *Gib and key*. The fixed wedge and the driving wedge for tightening the strap which holds the brasses at the end of a connecting-rod in steam-machinery.

**Giberne**, a French soldier's cartridge-box.

**Gibier** [Fr.], game; articles pursued or taken in the chase; venison.

**Gibraltar**. See SPAIN.

**Gibus**, a spring or folding crush dress-hat.

**Giddah, Giduah**, an Eastern grain measure of 2 lbs. 1 oz. 14 drachms; in some places it is only 2 oz., two giddahs making one arsolah, or the eighth part of the pucea seer.

**Gies**, strong mats made of bark or horse-hair-looking fibres, worn by native boatmen in the Pacific, to keep off the wet.

**Gig**, a shearing-frame used for cropping the nap or wool from cloth. — A long, light boat. — A light two-wheeled carriage for general use.

**Gig-Mill**, the cylinder in a cloth manufactory on which teasels or wire teeth are fixed, to card the cloth, which is stretched on beams.

**Gilbacker**, a fish of British Guiana, the *Silurus Parkerii*; from the sound isinglass is made, and exported to some extent.

**Gilder**, one who applies gold to substances. There are many kinds of gilders, as book and card-edge gilders, electro-gilders, china-gilders, French-gilders, water-gilders, screw-gilders, and gilders of glass, leather, etc.

**Gilding**, the application of a superficial coat of gold on wood, metal, and other materials. The beauty and durability of gold render it the most valuable of all ornamental substances; but, on account of its weight and high price, its use in these respects would be exceedingly limited, were it not the most extensible and divisible form of matter, so that it may be made to cover a larger surface than an equal quantity of any other body. For the sake of brevity we shall briefly notice the leading varieties of *G.*, and their application, in alphabetical order.

**Burnished G.** This is distemper *G.* to which a "face" has been given with the "burnisher." It is chiefly employed for the polished portions of the frames of pictures and mirrors, the more prominent parts of statuettes, etc.

**Cold G.** The articles (copper or brass) to be gilded, after being softened, annealed, and polished in the usual manner, are rubbed with a little *G.*-powder by means of a piece of cork moistened with a solution of salt in water; after which the work is burnished with a piece of hematite or polished steel.

**Distemper G.** This is applied to wood, plaster, marble, etc. It is commonly performed in this country by giving the wood, first, a coating of good size, and, next, several successive coats of size thickened with finely powdered whiting, Spanish white, or plaster of Paris, until a good face is produced, observing to let each coat become quite dry, and to rub it perfectly smooth with fine glass paper, before the application of the following one. When the proper face is obtained, the surface is thinly and evenly gone over with gold size, and when this is nearly dry, the gold leaf is applied, and afterwards burnished with an agate or dog's tooth. The process, as adopted by the Parisian artists, who greatly excel in this species of *G.*, is very compli-

cated, and is divided into at least 17 distinct operations, each of which they declare to be essential to its excellence.

**Electro-G.** See ELECTRO-METALLURGY.

**Grecian G.** In this variety sal-ammoniac and corrosive sublimate, equal parts, are dissolved in nitric acid, and a solution of gold made with this menstruum: after slight concentration the liquid is applied to the surface of silver, which immediately becomes black, but on being heated exhibits a rich gilded surface.

**Japanner's G.** The surface is covered with oil-size thinned with spirits of turpentine, and gold, in powder, is gently dabbed on with a puff of wash-leather. This gives the appearance of "frosted gold." A coating of varnish is next given, followed by exposure to a gentle heat in the "stove."

**Leaf G.** This term is commonly applied to the *G.* of paper, vellum, etc., by applying leaf gold to the surface, previously prepared with a coating of gum-water, size, or white of egg. It is usually burnished with an agate or dog's tooth.

**Oil G.** This species of *G.* may be divided into several operations. The following are the abridged instructions of a Parisian artist on the subject: 1. The surface is prepared by a coating of white lead in drying oil. 2. Another coat is given, made with calcined white lead or massicot, ground in linseed oil and turpentine. 3 or 4 coats of this mixture are often given, at intervals of at least 23 hours, observing to carefully smooth off each coat with pumice-stone or shave-grass before the application of the following ones. 3. The "gold color," or paint, is next applied. It is usually very adhesive gold-size, or the bottom of the pot or dish in which painters wash their brushes. For this purpose it is thoroughly ground and strained. 4. When the gold color becomes partially dry and sufficiently tenacious, the gold leaf is applied and pressed on with a wad of cotton-wool or a soft brush. It is now left for several days to harden. 5. A coat of spirit-varnish is next given, and the object is cautiously passed over a chafing-dish of charcoal, observing to avoid stopping the motion of the piece whilst doing so, as the work would then become discolored and blistered. 6. The work is "finished off" with pale oil varnish. For out-door *G.* and common work the varnishing process is generally omitted. This species of *G.* is applied to wood-work, plaster, metal, etc.

**Varnish G.** This is a mere variety of oil *G.*, applied to equipages, furniture, mirror, and picture frames, etc., the surface being highly varnished and polished before it receives the size or gold color; and after the *G.* has become quite dry a coat of spirit varnish, fumed with the chafing-dish as above, is applied, followed by 2, 3, or more coats of the best copal varnish, at intervals of 3 or 4 days each. The whole is, lastly, carefully polished with tripoli and water.

**Water G.** This consists in the application of a thin coating of amalgam of gold to the metallic surface (brass, bronze, or copper) to be gilded, and the subsequent volatilization of the mercury by heat. It is the usual method of *G.* articles of copper and its alloys, and possesses great beauty and durability when skilfully executed. The occupation is, however, an unhealthy one, owing to the continual exposure of the workman to the fumes of mercury. The furnace invented by M. D'Arcet obviates this evil, as the whole of the volatilized mercury is carried off, and again condensed for further use. It should, therefore, be adopted by every water-gilder who studies economy and the health of those in his employ. The process of water *G.* consists in several distinct operations, and can only be successfully performed by those who have been schooled in the art by an apprenticeship to the trade. It would, therefore, be waste of space to enter into details here. Formule for several of the articles employed for the purpose will be found in the alphabetical places in this work.

Among the applications of the process of gilding that deserve a separate notice are the following: —

**Books.** The gold letters and figures on the covers of books are thus formed: Gum mastic, in fine powder, is dusted over the surface to be gilded; an iron or brass tool bearing the design upon its face is then heated to a proper temperature, and gently pressed upon a piece of leaf gold, which slightly adheres to it; the two are then transferred to the cover, and the tool is gently pressed on it, by which means the mastic softens and retains the gold. The loose gold and powdered mastic are then dusted off with a brush. Gold leaf will adhere to leather without the use of mastic, but not so firmly as when it is employed. The edges of the leaves of books and paper are first cut perfectly smooth, and then washed over with a solution of isinglass in weak spirit, or with a varnish made of Armenian bole 4 parts, and powdered sugar-candy 1 part, mixed up to a proper consistence with strained white of egg. The coating is allowed to dry, and is then smoothed with a wet rag, after which the gold leaf is applied and polished with the burnisher.

**Brass Buttons**, formerly so much in demand, are covered by a rough species of wash *G.* The buttons are polished in the lathe and thrown into a pan with a little amalgam of gold, and as much aquafortis diluted with water as will wet them all over. Here they are well stirred up, until they assume a silvery appearance, when they are washed with clean water. They are then submitted to a sufficient heat, in a suitable apparatus, until the mercury is volatilized. The buttons

are next cooled, and well tossed and rubbed about with a painter's brush; and are, lastly, burnished by washing them well with beer or ale grounds. Twelve dozen (1 gross) of buttons, of 1 inch in diameter, may be perfectly gilded on both sides with only 5 gr. of gold. By an Act of Parliament, which is still unrepealed, this is the smallest quantity of gold permitted to be used for a gross of buttons of the above size.

**Glass, porcelain, and earthenware** are gilded by blending powdered gold with gum-water and a little borax, and applying the mixture by means of a camel-hair pencil; the article is then heated in an oven or furnace, by which means the gum is burnt, and the borax, vitrifying, cements the gold to the surface. It is afterwards polished with a burnisher. Names, dates, or any fancy device may thus be permanently and easily fixed on glass, china, earthenware, etc.

**Japanned work** is gilded by the method explained as "Japanner's gilding" (above).

**Leather** is gilded in the same way as the covers of books. (See above.) For common work, silver leaf, or even tin foil, is applied to the surface, previously covered with size or white of egg, and after being burnished down and dried, is washed over with gold-colored lacquer.

**Letters of sign-boards and the ornamental G.** for out-door work are done by first covering the design with yellow paint, then with oil gold-size, and when this is nearly dry applying the leaf gold, observing to shield it properly from the wind, lest it be blown away or become crumpled before being properly attached. The work is, lastly, varnished.

**Polished metals** may be gilded by one or other of the methods already noticed. Articles in silver, copper, brass, and bronze are usually coated by the process of wash or water gilding; or, directly, by the application of gold leaf, as follows: The piece or article is heated to a bluish tint, and gold leaf pressed gently and carefully on it with the burnisher; heat is again applied, and the process repeated with fresh leaves of gold until the gilding has acquired the proper thickness and tone. The surface is lastly polished with the burnisher, or is colored in the usual manner at the stove. This succeeds with iron, steel, silver, copper and its alloys, etc. Another method for polished articles in iron and steel, which, however, is less durable than the preceding, is to apply an ethereal solution of gold to the surface with a camel-hair pencil. The ether flies off and leaves the surface coated with gold, which is then polished as before. In this way any fancy device or writing may be executed on steel or iron with extreme facility.

**Silks, satins, woolsens, tery, bone, etc.**, may be readily gilded by immersing them in a solution of neutral terchloride of gold (1 of the salt, and 3 to 6 of water), and then exposing them to the action of hydrogen gas. The latter part of the process may readily be performed by pouring some dilute sulphuric acid on zinc or iron filings, in a wide-mouthed bottle, and placing it under a jar inverted, at the top of which the articles to be gilded are suspended. Flowers or other ornamental designs may be produced by painting them on the surface with a camel-hair pencil dipped in the solution. The design, after a few minutes' exposure to the hydrogen, shines with all the splendor of the purest gold, and will not tarnish on exposure to the air, or in washing.

**Wire** (copper, silver, or brass) is occasionally gilded, in coils, by a process similar to that adopted for *Buttons*; but more frequently as follows: Rods (usually of silver) are covered with gold foil of a thickness proportionate to the quality of the intended wire, and the compound bar is then drawn into wire, in the usual way.

**Gilding Liquor** is the name given to various liquids employed in *G.* Among them are the following: **Deating Aquaforis.** From mercury, 1 part; aquafortis (sp. gr. 1.33), 3 parts; dissolve, and add of soft water, 3 parts. Used to produce a dead-gold effect. It is applied (diluted) to the articles, before spreading the amalgam over them, in water *G.*—**Mercurial solution.** From mercury, 10 parts, dissolved in aquafortis, (sp. gr. 1.33), 11 parts, and the solution diluted with 25 times its weight of water. Used to moisten the scratch brush before drawing it over the amalgam, in mercurial *G.*; also to deaden the gilded surface, by moistening the piece to a heat sufficiently high to drive off the mercury. — **Gilder's Pickle.** From alum and common salt, of each 1 oz.; nitre, 2 oz.; dissolved in water, 1 pint. Used to impart a rich color to gold surfaces, especially of trinkets. Its application should not be too long continued, as it dissolves a small portion of the gold. For common purposes it is best used largely diluted with water.

**Gilding Metal.** The metal employed as a base for *G.* is usually brass, or a mixture of brass and copper. The following proportions have been recommended: (1) Copper, 6 parts; brass, 1 part. (2) Copper, 4 parts; Bristol brass, 1 part. (3) Copper, 13 parts; old Bristol brass, 3 parts; tin, 14 parts.

**Gilding Powder.** Pure gold, 3 dr.; pure copper, 1 dr.; aqua regia 10 oz.; dissolve, moisten clean linen rags with the solution, dry them, and burn them to ashes. The latter contain the gold in a state of minute division, and must be carefully collected.

**Gilding-Size**, a pure description of size for the use of gilders.

**Gilead (Balm of).** See *OPONALSAM*.

**Gill**, a liquid measure, the fourth part of a pint, and weighing 5 oz. avoirdupois of water. — A pair of wheels and a frame on which timber is carried.

**Gillosanto**, a pastel, or coloring substance, made of argol and rhamnus or yellow berries.

**Gimbal, Gimmel**, the brass ring by which a ship's compass is suspended in its box.

**Gimbal-Joint**, a two-part joint having articulations on axes at right angles to each other.

**Gimblet**, a carpenter's boring instrument, to screw round, to turn anything on its end, as an anchor round by its stock. It has a leading screw, a grooved staff, and a cross handle.

**Gimmel.** See *GIMBAL*.

**Gimp**, silk thread or twist, usually interlaced with a metallic wire, used for dress trimmings, in coach-lace making, and for fringes.

**Gimp-Nail**, a small forged nail with a rounded head, used by upholsterers.

**Gin**, a portable machine for raising weights, driving piles, etc., which consists of three spars set up in a pyramidal form, and furnished at top with a tackle which is worked by a windlass beneath. — A machine for opening the tufts of cotton after gathering (see *COTTON*).

**Gin** [a corruption of *geneva*], an ardent spirit, distilled from corn, and flavored with either oil of juniper or oil of turpentine. Gin was originally wholly imported from Holland, and was a rich, soft spirit, flavored chiefly with juniper berries, on which account it had obtained the name of *geneva* (from *genièvre*, the French for juniper). After a time the distillation of an imitation geneva sprung up in England, where the continental spirit came to be called *Hollands*, or *Hollands geneva*, to distinguish it from the spirit of English manufacture. The liquor at present known by the name of gin, both in England and America, is a very different article from that imported from Holland (see *HOLLANDS*), and consists of plain corn-spirit, flavored with oil of turpentine and small quantities of certain aromatics. The thousand and one receipts for this article, which have from time to time been printed in books, produce a flavored spirit bearing no resemblance to the more esteemed samples of English gin; and, if possible, the products are even more unlike genuine Hollands. Any person may easily satisfy himself of the truth of this assertion by actual experiment on the small scale. The cause of this incongruity has arisen chiefly from the writers not being practically acquainted with the subject, and from the disinclination of well-informed practical men to divulge gratuitously what they conceive to be valuable secrets. Hence the utter failure of any attempts to produce either gin or Hollands from the receipts usually published. Theory and experiment sometimes disagree. In practice, it is found that the true flavor of foreign geneva cannot be imparted to spirit by juniper alone, and that the English gin of the present day depends for its flavor on no such substance. The following formulae are merely given as specimens; and it is proper to remark, that every distiller has his own receipt for this notorious beverage. Hence it is that the gins of no two distillers are of precisely the same flavor; and this difference is still more marked when the distillers reside in parts of the country remote from each other. Booth's, Smith's, Nicholson's, Swan's, gins, etc., have each a characteristic flavor, readily perceived by their respective votaries. These variations in flavor generally depend on the use of

more or less flavoring matter, or of a spirit more or less clean or free from taint; and less frequently on the addition of a small quantity of some peculiar aromatic, which exercises a modifying influence on the chief flavoring ingredient. In many cases the flavor has originated from accident, but the consumers having become accustomed to, and hence relishing, that particular "palate," it is found to be unwise or commercially impossible to alter it. Any change in these matters is therefore looked upon in every distillery as a dangerous innovation, which would prove more prejudicial to the prosperity of its exchequer than the repeal of the duty on French wines and brandy, or even a frightful conflagration. The distillers, like the brewers, are thorough conservatives in all matters connected with the flavor of their liquors.

**Preparation:** (1) Clean corn spirit, at proof, 80 galls.; newly rectified oil of turpentine,  $\frac{1}{2}$  pint: mix well by violent agitation, add culinary salt, 14 lbs., dissolved in water, 40 galls.; again well agitate, and distil over 100 galls., or until the fumes begin to rise. **Product**, 100 galls. of gin, 22 u. p., besides 2 galls. contained in the fumes. If 100 galls. at 17 u. p. are required, 85 galls. of proof spirit, or its equivalent at any other strength, must be employed. (2) Proof spirit (as above), 8 galls.; oil of turpentine, 1 fl. oz.; salt,  $\frac{1}{2}$  lb., dissolved in water, 4 galls.: draw over 10 galls., as before, 22 u. p. (3) Clean corn spirit, 80 galls.; oil of turpentine, 1 pint; pure oil of juniper, 3 fl. oz.; salt 21 lbs.; water, 35 galls.; draw over 100 galls., as before, 22 u. p. (4) To the last, before distillation, add, of oil of caraway,  $\frac{1}{2}$  fl. oz.; oil of sweet fennel,  $\frac{1}{2}$  fl. oz.; cardamoms (ground), 8 oz. (5) To No. 3 add, of essential oil of almonds, 1 dr.; essence of lemon, 4 dr. (6) To No. 1, before distillation, add of creosote 3 fl. dr. (7) To No. 3 add of creosote, 2 dr. (8) Proof spirit, 80 galls.; oil of turpentine,  $\frac{1}{2}$  pint; oil of juniper,  $\frac{1}{2}$  pint; creosote, 2 dr.; oranges and lemons, sliced, of each 9 in in.; macerate for a week, and distil 100 galls., 22 u. p.

In the preparation of gin, both sweetened and unsweetened, and indeed of liquors generally, the greatest possible care must be taken to avoid an excess of flavoring. The most esteemed samples are those that consist of very pure spirit, slightly flavored. The oil of turpentine used in this manner should be of the best quality, and not that usually vended for painting, which always contains resin and often fixed oil. Juniper berries, bitter almonds, and the aromatic seeds may be used instead of the essential oils; but the latter are the most convenient. Turpentine conveys a plain gin flavor; juniper berries or oil gives a Hollands flavor; creosote imparts a certain degree of smokiness, or whiskey flavor; lemon and the other aromatics a creaminess, fullness, and richness. The flavor imparted by cardamoms, when used judiciously, is peculiarly agreeable and appropriate. That from caraways is also in general esteem. Cassia in extremely small proportions also tells well. Fused oil gives a whiskey-gin flavor; and in conjunction with creosote or crude pyroligneous acid a full whiskey flavor. The only danger in the employment of all these articles is using too much of them. When this misfortune happens, the remedy is to add sufficient plain spirit to reduce the flavor to the proper standard. The creaminess and smoothness so much admired in Hollands results chiefly from age. The English rectifier endeavors to imitate this by the addition of a little sugar. A rich mellowness, that combines well with gins turning on the "Hollands flavor," is given by a very small quantity of garlic, and with Canadian balsam or Strasburg turpentine. The peculiar piquancy, or the property of "biting the palate," regarded as a proof of strength and quality by the ignorant gin-drinker, is imparted to the liquor by the addition of a little caustic potassa. Sliced horse-radish gives piquancy as well as mellowness. Grains of paradise, cayenne-pepper, and sulphate of zinc are also commonly added by fraudulent dealers. — Although gin is always prepared on the large scale by distillation, it may also be made by the simple solution or digestion of the flavoring ingredients in the spirit; but it is, of course, better for distillation. If made in the former way, no salt must be employed. The gin produced by the above formulæ is that denominated in the trade *unsweetened gin*, *groz gin*, etc.; but much of the gin sold in the bars is a sweetened spirit, and hence is technically distinguished by the terms *sweetened*, or *made up*. To ascertain whether gin is sweetened or not, a little may be evaporated in a spoon, over a hot coal or a candle, when, if it is pure, it will leave the spoon scarcely soiled; but if, on the contrary, it has been sweetened, a small quantity of syrupy liquid, or sugar, will be obtained, the sweetness of which may be easily recognized by tasting it. — The whole of the casks and utensils employed for gin should be perfectly clean, and properly prepared, so as not to give color; as, if this spirit acquires the palest colored tint, its value is lessened, and if much colored it is rendered unsalable. When gin has once become much

stained, the only remedy is to re-distill it; when it is only slightly stained, the addition of a few lbs. of acetic acid to a pipe or butt, a spoonful or two to a gallon, or a few drops to a decanterful, will usually decolor it, either at once or as soon as it is mixed with water to make grog.

**Sweetened gin, Gin cordial.** Good gin (22 u. p.), 90 galls.; oil of almonds, 1 dr.; oils of cassia, nutmeg, and lemon, of each 2 dr.; oils of juniper, caraway, and coriander, of each 3 dr.; essences of orris-root and cardamoms, of each 5 fl. oz.; orange-flower water, 3 pints; lump sugar, 56 to 60 lbs.; dissolved in water, 4 galls. The essences are dissolved in two quarts spirit of wine, and added gradually to the gin until the requisite flavor is produced, when the sugar (dissolved) is mixed in, along with a sufficient quantity of soft water, holding 4 oz. of alum in solution, to make up 100 galls. When the whole is perfectly mixed, 2 oz. of salt of tartar, dissolved in 2 or 3 quarts of hot water, are added, and the liquor is again well rummaged up; after which the cask is bunged up, and allowed to repose. In a week, or less, it will have become brilliant, and may be either "racked," or drawn from the same cask. **Product**, 100 galls., about 30 u. p.

**Imp. duty**, as alcohol.

**Ginger** [Fr. *gingembre*; Ger. *Ingwer*; It. *zenzero*; Port. *gingivire*; Sp. *jingibre*], the root of a plant (*Amomum zingiber*) cultivated throughout both the East and West Indies and China, and used as a spice. It occurs in knotty branched pieces, having a pleasant aromatic odor and biting taste. There are two varieties, the black and the white. *Black G.* consists of the inferior roots, which have been immersed in boiling water previously to being dried, and has thus a horny texture. *White G.* consists of the fairest and roundest roots, peeled when fresh, and dried in the sun. It is firm and resinous, more pungent than the black, and generally one third dearer. The roots which are worm-eaten, light or soft, and very fibrous, are to be rejected. *Preserved G.*, as manufactured in Europe, is dark and fibrous; but when prepared in the East or West Indies or China, from the young roots, it is almost transparent. It is imported in jars, and should be chosen in large pieces of a bright yellow color.

**Imp. duty:** the green, fresh, or dried root, free. — Ground, 3 cts. per lb. — Preserved or pickled, 35 per cent. — Essence of, 35 per cent.

**Ginger-Beer**, a popular effervescing, bottled drink, flavored with sugar.

**Manuf.** Take of white sugar 20 pounds, lemon or lime juice 18 fluid ounces, honey 1 pound, bruised ginger 22 ounces, water 18 gallons. Boil the ginger for half an hour in three gallons of the water, then add the sugar, the juice, and the honey, with the remainder of the water, and strain the whole through a cloth: when cold, stir in the white of one egg and half an ounce of essence of lemon; after standing four days, bottle. The bottles are to be laid on their sides in a cellar; and the beer is ready for use in about 3 weeks. If a little yeast be used, the beer is ready in two or three days, but in that case does not keep well.

**G.-B. powder.** Take of white sugar two drachms, bicarbonate of soda 26 grains, powdered ginger 5 grains, essence of lemon 1 drop; mix and put up in a white paper. In a blue paper put up half a drachm (30 grains) of finely powdered tartaric acid. When used, mix the powders and stir them into half a pint of water.

**Gingerbread**, a baked cake made of flour, treacle, and butter, with ginger and other spice, which will keep for some time.

**Ginger-Grass (Oil of).** See GERANIUM.

**Ginger-Wine**, a popular and cheap liquor, made by the fermentation of sugar and water, and flavored with various substances, but chiefly with ginger. It is partly an article of domestic manufacture, and is partly made on a larger scale for sale.

**Gingham, BENGAL STRIPS**, a cotton cloth generally bearing a colored check pattern, which is not produced by dyeing or stamping the manufactured material, but by interweaving colored threads. The various kinds of *G.* now manufactured are known by different names in commerce;

and umbrella *G.* is woven with threads all of the same color.

**Ginning**, the operation of cleaning cotton-wool from the seeds, by an apparatus called a gin. See **COTTON**.

**Ginseng**, the root of the *Panax schinseng*, which was formerly regarded in China as a panacea for nearly all diseases, and realized an enormous price in consequence. It is still highly esteemed there, but American and English practitioners look upon it as a comparatively inert substance. An allied species, *Panax quinquefolium*, grows wild in the northern, middle, and western States, and the roots, which are two or three inches long and about as thick as the little finger, are collected and brought to the seaboard cities, particularly to Philadelphia, from whence they are exported to China.

**Gipsy-Winch** is a small winch having a drum, ratchet, and pawl, and attachable to a post.

**Girandole**, a branch burner or chandelier for gas. — A stand for candles or flowers.

**Girard**, a fire and marine insurance Co., located in Philadelphia, Pa., organized in 1853. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$300,000; net surplus, \$527,840.51; risks in force, \$40,923,244; premiums, \$488,291.62; premiums received since the organization of the Co., \$4,650,897.80; losses paid, \$1,957,147.32; cash dividends paid to stockholders, \$583,331.

**Girders**, beams of wood or iron for supporting the superincumbent weight in any erection, as in houses, bridges, etc.

**Girdle**, a belt. — A circular plate of malleable or cast iron, used in Scotland for toasting cakes over a fire. — The point of greatest marginal circumference of a brilliant-cut diamond, at which it is grasped by the *setting*.

**Giro** [Ger.], endorsing. There are Giro banks at Frankfort, Hamburg, etc., which transact this species of business.

**Girth**, the circumference or round measurement of timber, etc. — The belly-strap for a saddle.

**Git**, in foundling, the entrance for molten metal into a mould.

**Glace**, the French word for looking-glass, and also for ice.

**Glance-Cotton**, cotton threads or yarn twisted, gummed, and highly finished, used as warps for velvets, trimmings, etc., made in Leicestershire, England; also glace sewing-cotton.

**Glance-Silk**, a kind of shaded silk for ladies' dresses.

**Glaire**, the white of eggs, used as a size in book-binding.

**Glance**, a term for certain minerals which have a metallic lustre, as *glance coal* (for which see **ANTHRACITE**).

**Glance-Wood**, a hard wood imported from Cuba, and used for making carpenters' rules, gauging instruments, etc.

**Gland**, the cover of the stuffing-box of a steam-engine. — Also generally applied in the sense of a joint holding lubricating fluid, with tight packing.

**Glareous**, viscid and transparent, like the white of an egg.

**Glasgow**. See **GREAT BRITAIN**.

**Glass** [Fr. *verre*; Ger. *Glas*; It. *vetro*; Sp. *vidrio*]. The general term *glass* is employed by chemists to denote all mineral substances which, on the application of heat, pass through a state of fusion into hard and brittle masses, and which, though not always transparent, exhibit a lustrous

fracture when broken. The *G.* of commerce, however, to which our remarks are restricted, or the transparent and artificial substance which is usually distinguished by the generic name, is produced by the igneous fusion of siliceous earth with certain alkaline earths or salts, or with metallic oxides. In its usual form it is brittle, transparent, non-crystalline, insoluble, and fusible; but it sometimes exhibits other properties.

In the most remote ages the art of blowing *G.* into bottles, making it into vases, coloring it to imitate precious stones, melting it into enormous masses to make pillars, rolling and polishing it into mirrors, and tinting it into parts, were all perfectly well known. For its origin we must look to Egypt (Fig. 233), the parent of so many collateral arts. Some authors ascribe, with very plausible reason, the discovery of *G.*-making to the priests of Vulcan at Thebes and Memphis, the greatest chemists in the ancient world. The Egyptians are also known to have made enamels of divers colors which they applied on pottery, magnificent specimens of which are still extant, and

Fig. 233. — EGYPTIAN GLASS-BLOWERS.  
(From the Tombs at Thebes.)

are called Egyptian porcelain. These are chiefly covered with beautiful blue or green, and groups of flowers or designs are traced in black. *G.* beads, and other ornaments made of that substance, skillfully manufactured and beautifully colored, have been found adorning mummies which are known to be upward of 3,000 years old. It is certain that Tyre, Sidon, and Alexandria were long celebrated for their *G.*, and furnished the greater proportion of that used at Rome. To these places the art was exclusively confined for some centuries, and was an article of luxury, being chiefly in the form of urns or drinking-cups of the most elaborate workmanship, and exquisitely embellished with raised, chased, or ornamented figures. The Barberini or Portland vase, composed of deep blue glass, with figures of a delicate white opaque substance raised in relief, is a splendid specimen, and was found in the tomb of Alexander Severus, who died A.D. 285. The precise period at which the making of window-*G.* came into practice is not certainly known. The Roman windows were filled with a semi-transparent substance called *lapis specularis*, a fossil of the class of mica, which readily splits into thin, smooth laminae or plates. The Romans were chiefly supplied with this article from the island of Cyprus, where it abounds. There is no positive mention of the use of *G.* for windows before the close of the 3d century. *G.* windows are distinctly mentioned by St. Jerome as being used in his time (A.D. 422). After this period we meet with frequent mention of them. It is asserted

that *G.* windows were first introduced into England in the year 674, by the Abbot Benedict, who brought over artificers skilled in the art of making window-*G.*, to glaze the church and monastery of Wearmouth. The use of window-*G.*, however, was then, and for many centuries afterward, confined entirely to buildings appropriated to religious purposes; but in the 14th century it was so much in demand, though still confined to sacred edifices and ornamental purposes, that glazing had become a regular trade. Until this period they were rarely to be found in private houses, and were deemed a great luxury, and a token of great magnificence. The windows of the houses were till then filled with oiled paper or wooden lattices. The *G.* of the Venetians was superior to any made elsewhere, and for many years commanded the market of nearly all Europe. The skill of the Venetians was especially remarkable in the excellence of their mirrors. The art of *G.*-making seems to have been introduced in France in the 13th century, and in England a century later. The manufacture of *G.* was introduced into the American States in 1790 by Robert Hewes, a citizen of Boston, who erected a factory in the then forest of New Hampshire. The chief aim of Mr. Hewes was to supply window-*G.*, but he did not succeed. Another attempt was made in 1800, when a factory was built in Boston for making crown window-*G.*; but this was also unsuccessful, till a German named Lint, in 1803, took charge of the works, and the State of Massachusetts agreed to pay the proprietors a bounty on every table of window-*G.* they made; after which the manufacture was carried on successfully, the *G.* steadily improving in quality, and becoming famed through all the States as Boston window-*G.* Above 50 companies have been since formed in the Eastern States, most of which have proved failures. There are now important manufactories of *G.* at Boston, Cambridge, Sandwich, New York, Philadelphia, Pittsburg, etc.; but this industry does not seem to be yet fully naturalized in this country, and we continue to pay yearly to Europe a heavy tribute for our supply of *G.* of every description. The total value of *G.* imported into the U. States, for the year 1878, was \$3,333,149. Window-*G.* comes principally from Belgium; plate-*G.* and *G.*-ware from Germany, England, France, and Belgium.

*Manuf.* The manufacture of *G.* is one of the highest beauty, and, considering the comparative worthlessness of the materials of which it is made, and the various purposes of a useful, ornamental, and scientific nature which it subserves, it may be regarded as perhaps the most important in the history of inventions. The principle of its production is very simple,

Fig. 234. — GLASS-FURNACE.

although great skill and experience are necessary to insure its excellence. Silica (commonly under the form of sand) is heated with carbonate of potassa or of soda, and slaked lime or oxide of lead, until the mixture fuses, and combination takes place. After a time the melted mass becomes perfectly limpid and free from air-bubbles, when it is allowed to cool until it assumes the peculiar tenacious condition proper for working. The operation of fusion is conducted in a furnace (Fig. 234), circular in form, and of sufficient size to admit 8 or 12 large melting-pots. Doors in the wall of the furnace give access to these

pots, and the low-domed roof causes the heat to be reflected down upon them. These pots are made of well-prepared and well-annealed clay; some of them are 3 feet wide, 4 feet high, weigh 10 cwt., and will contain 16 to 20 cwt. of glass. They are closed on all sides, except a projecting mouth near the top

Fig. 235. — BOTTLE-MAKING.

of one side. The *frit* (the name given to the powder into which the constituents of *G.* are reduced before melting) is thrown into the pots through the furnace doors; the doors are closed; the heat is urged to the highest point; and then the *frit*, melted into a golden liquid *G.*, is ready for use. — The chief kinds of *G.* are *Bottle-G.*, *Crown-G.*, *Flint-G.*, *Optical G.*, *Plate-G.*, *Sheet-G.*, and *Stained G.*, here noticed in their alphabetical order.

*Bottle G.* The mixture for common bottles is as follows: yellow sand 20, kelp 8, fixivated wood-ashes 30, fresh wood-ashes 8, pale clay 16, *cullet* (broken *G.*) 18 = 100. Bottles are made by blowing and rolling. The workman begins by collecting a proper quantity of *G.* in a soft, pasty state, at the end of his blowpipe (an iron tube, five or six feet in length, terminated by a mouthpiece of wood), which he then commences blowing through, by which the lump is expanded (Fig. 235) into a kind of flask, *a, b*, susceptible of having its form modified by the position in which it is held, and the velocity of rotation continually given to the iron tube. The bottle is then introduced in a mould, *c*, when it is blown to the wanted size. Then an iron rod, called a *pontil*, is dipped into the *G.*-pot and applied to the bottom of the flask, to which it thus serves as a handle, the blowpipe being removed by the application of a cold iron to the neck. The bottle is now re-heated, and the aperture finished, and the vessel otherwise altered in figure, *d, e*, by the aid of a few simple tools until completed. It is then detached, and carried to the *annealing oven*, where it undergoes slow and gradual cooling during many hours. Beer and wine bottles are now generally made as follows: The mass of molten *G.* at the end of the tube is inserted in an iron mould, which gives the external form, while the hollowness is produced by blowing through the tube. To make *carboys*, use is made of steam produced by spitting a mouthful of water through the blowing-tube, the end of the tube being covered by the thumb.

*Crown-G.* is the best kind of window-*G.* The hardest and most colorless is a mixture of silica 63, potash 22, alumina 3 = 100. It is harder than flint-*G.*

*Bohemian G.*, in its composition, is similar to the above in respect to the absence of lead in notable quantities. It is a silicate of potash and lime, with a little silicate of alumina. It is very hard, transparent, and difficult to fuse.

*Crown-G.* is made in round disks by the following process: The materials are fritted in a reverberatory furnace, and then melted in a pot. A lump of *G.* sufficient to make a *table* of nine pounds weight is extracted at the end of a *blowing-tube*, and is distended into a pear-shape by blowing through the tube and rolling on the *marver*, which is a cast-iron slab on a stand. Being softened by heat at the mouth of a small blowing-furnace, it is rolled on the marver, and blown till it assumes a more spherical shape, but has a conical end, which is removed as the *G.* approximates a spherical form, being blown as it is rolled on the *bullion-bar*. Being again heated at the blowing-furnace, rotation and blowing being persevered in, it becomes spherical. It is then presented at a larger furnace-hole, called the *bottoming-hole*, and, being rapidly rotated, becomes oblate. A *pontil* tipped with molten *G.* is then applied to the centre of the flat portion, and the blowing-tube is detached by touching the neck of the globe with a cold wet iron. This leaves a hole in the end from which the blowing-tube was detached. Heat and rotation being still applied, first at a furnace-opening of moderate size called the *nose-hole*, and then at a much larger one called a *flashing-furnace*, the hole becomes more and more enlarged as the article becomes more and more oblate. Finally it flies open with

a sharp, rustling noise, and appears as a flat plate, called a *table*, adhering at its central, thicker portion, the *bull's-eye*, to the pontil, by which, during the later portions of the process, it was rested on the hook in the half-wall before the furnace, which formed a partial screen for the workman. When it has cooled sufficiently to be rigid, and not liable to bend or collapse, it is placed on a fork, the pontil detached by the application of a cold iron, and the table placed in the annealing arch or kiln, where it rests on its edge for perhaps twenty-four hours, gradually cooling. — *Knight's Am. Mechanical Dict.*

*Cylinder G.* See *sheet-G.*, below.

*Flint-G.* consists of silica 52, potash 22, alumina 1, oxide of lead 32, oxide of iron 2 = 100. By dexterous handling, the blower takes up by the blowing-tube just as much *G.* as will make the decanter, claret-jug, goblet, wineglass, or whatever article is to be made. The *G.*, which has a consistence somewhere between paste and putty, is rolled a little on a marver (see *crown-G.*); it is expanded by blowing through the tube; it is gently touched here and there with wooden and iron tools; it is kept rotating to prevent it from falling off the end of the tube; and in a way which is scarcely conceivable even to a by-stander, it assumes the form of a shapely article. The *G.* requires then to be annealed. It must be cooled slowly, otherwise the substance will be brittle; and the mode of effecting this cooling constitutes the annealing. The annealing oven is called a *leer*, or *leary*; it is a very long narrow arch, kept highly heated at one end, and gradually colder and colder towards the other. The articles in *G.*, placed upon iron trays, are pushed into the heated end of the oven: others are pushed in after them as fast as made; each tray reaches a slightly cooler region at each movement; and after many hours the fragile products are removed quite cold from the remote end of the leer. Other plans are occasionally adopted; but this is the usual mode of annealing.

*Optical G.* The *G.* required by the makers of high-class telescopes, microscopes, prisms, etc., is the best which art can produce; seeing that any flaw, streak, or spot becomes magnified as a defect in the using of the instrument. Scrupulous choice of ingredients, and delicate processes of making, are indispensable. If the ingredients are not well mixed and diffused, the glass will have a higher optical power at one part than at another; if any of the grains of sand or flint are imperfectly fused, they produce spots; if one side of the melting-pot be hotter than another, the *G.* will be unequal in quality; if the cooling be either too quick or too slow, irregularities of other kinds arise. Hence a piece of really perfect *G.*, large enough to make the object-lens for an equatorial telescope, or a transit instrument, is valued very highly. *G.* for ordinary instruments, with 10 per cent increase of oxide of lead, is, after careful mixing and melting, blown into cylinders, which are cut open into slabs about 14 inches by 10, and half an inch or so in thickness; the optician cuts off pieces from this slab to grind into lenses of the sizes needed. A very perfect, but not very durable, optical *G.* is made of a combined silicate and borate of lead, according to a plan suggested by Dollond, Herschel, Faraday, and Roget. Numerous researches have been made by Guinand, Fraunhofer, Merz, Bontemps, Daguet, and Chance to produce optical *G.* of high quality. Disks of large size have been displayed at the various international exhibitions, some as large as 29 inches diameter, with results so far satisfactory as to encourage further experiments. It may here be mentioned that, as the object-glasses of achromatic telescopes are made by a combination of flint-*G.* and crown-*G.* lenses, those two kinds of *G.* must be equally studied to attain good results.

*Plate-G.* This is in some respects the most beautiful of all kinds of *G.*, on account of its transparency, colorlessness, high polish, absolute flatness, and facility of being silvered. It consists of silica 78, potash 2, soda 13, lime 5, alumina 2 = 100. The manufacture differs in many important particulars from that of other kinds of *G.*, as the following brief account will show: The melting-pots are very large, some of them holding as much as 3½ cwt. of *G.*. When the molten mass is ready for use, a large copper ladle, held by a long handle, is employed to ladle it out from the melting-pots into other pots called *cisterns*, where it is allowed to fine or refine by settling, and to lower somewhat in temperature. The *casting-table* then comes into use. This is made of iron, brass, or bronze, and is always as perfect a slab as the art of the metallurgist can produce, — beautifully even, flat, and smooth, sometimes as much as 20 feet long by 11 broad, and 7 inches thick. There is a framework round this slab which facilitates the operations. (Huge tongs take the cistern out of the furnace; a crane lifts it up, and places it in a peculiar position over one end of the table; the slab is heated to a certain temperature; the cistern is tilted up, and the golden stream flows all over the table, being prevented by raised edges from running over. A large copper cylinder then rolls to and fro, bringing the molten *G.* to a uniform level and thickness. When sufficiently solidified to be moved, the immense sheet of *G.* is pushed end on into an annealing oven, which is built close to it. When the *G.* is annealed it is ready for *grinding*, to give smoothness to surfaces which are as yet somewhat rough. This is done by rubbing one *G.* upon another, the upper *G.* being temporarily fixed to a frame which has peculiar gyratory movements given

to it by steam-power. Sand of three different degrees of fineness and water are used to assist this grinding. The *G.* was half an inch thick in the first instance; but the grinding repeated in succession on both surfaces greatly reduces the substance. The *G.* is now smooth but dull; it still wants *polishing*. This is done, first by emery and water, and then by felt rubbers, applied in various ways. Sometimes plate-*G.* is made by the cylinder method, described below under *sheet-G.*, followed by the grinding and polishing processes. See *MIRROR*.

*Sheet-G.* (also called *Cylinder*, *Broad*, *Spread*, *German G.*) is a mode of manufacturing which is as remarkable in its way as that of crown-*G.* The workman collects a quantity of molten *G.* on the end of his blowing-tube, rolls it on an iron

Fig. 236. — BLOWING SHEET-GLASS.

slab, blows through the tube, reheats the mass of *G.*, keeps the tube rotating on its axis, and so continues until the *G.* extends as a sort of irregular, bottle-shaped globe beyond the lower end of the tube (Fig. 236). Then swinging the rod several times in a great vertical circle, the *G.* elongates into a sort of sugar-loaf, with the broad end attached to the tube. The apex of the sugar-loaf bursts open, and there is then produced an open cylinder, attached in a surprising way by its closed end to the tube. All this time the *G.* is in a glowing state; and the alternate rolling, rotating, blowing, and swinging are continued until the substance assumes a solid consistency, although still quite hot. By the aid of a few tools the cylinder is brought to a true shape while still somewhat soft; by a touch with a wetted iron rod it is separated from the tube; by a line drawn with another wetted rod it is split open from end to end, ready to be spread out as a flat quadrangular sheet. The cylinder is transferred to the *flattening-furnace*, with the slit uppermost; the heat causes it to open, and a workman flattens it out with a wooden polisher moistened with water. However carefully this process may be conducted, there is always a *teariness* in the *G.* which detracts from its otherwise useful qualities in glazing prints and drawings. Sheet *G.* is especially useful in glazing large structures, such as exhibition buildings, railroad stations, etc.

*Stained G.* differs materially from *painted G.*, although the terms are frequently used synonymously. In stained *G.*, the substance of the *G.* itself has been colored throughout in the process of manufacture, while in painted *G.* the *G.* is only painted on the surface. Real stained *G.* is simply *colored G.*, and the color is almost always given by adding certain metallic oxides to the other ingredients. Many ancient nations were acquainted with modes of making colored *G.*; but it is not certain what kind of chemical agents they employed. Oxides of gold tend to produce red tints; those of copper tend towards green; those of manganese purple; and so on with other oxides and chlorides. The *G.-stainer* ought, therefore, to possess a good knowledge of the chemistry of colors. *G.* colored throughout the mass is called *pot-metal*; and it is called *flushed G.* when the colored material is put on as a superficial coating. When *G.* is to be stained throughout, the coloring ingredient is mixed with the sand, alkali, and other ingredients in the *G.-pot*, and melted all together; or else good white transparent *G.* is remelted, and the metallic oxides combined with it in that state. When it is to be stained on one surface only, the *G.-blower* has two pots in the furnace, one with transparent and the other with colored *G.*. He dips his blowing-tube into the former, and takes up the requisite quantity of *G.*; after rolling and setting it a little, he dips it for a moment into the colored *G.*, of which he takes up a thin film. The blowing and finishing are then proceeded with, leading to the production of *G.* with a thin colored film on a white foundation. See *WINDOW-G.*, *CROWN-G.*, *SHEET-G.*, and *G.-PAINTING*.

*Glass Tubes* are made by rapidly drawing out a hollow cylinder; and from these a great variety of useful small apparatus are constructed with the help of a lamp and blowpipe, or, still better, the bellows-table of the barometer-maker. *G. beads* are made from small tubes chopped into pieces of suitable lengths, which are stirred first in a mixture of sand and wood-

ashes, in the cold, and afterwards in an iron pan over the fire until they assume a rounded form. *Small tubes* are bent in the flame of a spirit-lamp or gas-jet, and cut by a file, a scratch being made, and the two portions pulled or broken

Fig. 237. — DIFFERENT STAGES IN SHEET-GLASS MAKING.

asunder in a way easily learned by a few trials. *Large tubes* require the heat of a powerful blowpipe and lamp, or that of a furnace.

**Cutting G.** The kind of *G.* mostly used for ornamental cutting is flint-*G.* It is cut by means of wheels, of different sizes and materials, turned by a treadle, as in a common lathe; some are made of fine sandstone, some of iron, others of tin or copper; the edges of some are square, some are round, and some are sharp. They are used with sand and water, or emery and water, but stone wheels are used with water only. The *G.*-cutter also uses rods of copper, with knobs at their ends, for making round indentations; these turn on their axis, so that the end cuts a round hollow in the glass. The work is at first cut roughly, afterwards smoothed off with the sandstone or tin wheel,—the latter has to be smeared with emery and water,—and finally polished by a wooden wheel, with finely powdered pumice-stone applied to its edge, and moistened with water. The glass for spectacles and optical instruments is cut by concave or convex moulds of brass, moistened with emery and water, and polished by means of a mould of pitch, wetted with crocus and water.

**Grinding G.** This on the large scale, like *G.*-cutting, forms a distinct occupation. Great art and accuracy are required to grind the glasses for optical instruments, especially very large or very small ones, as for microscopes, the various "powers" of which constitute their chief expense,—one the sixteenth of an inch in diameter costing about \$60. On the small scale, *G.* may be roughened or ground by friction with powdered emery and water and a flat rubber of wood, care being taken that the article, if a plate, is laid on a perfectly flat surface, or, if hollow, is supported by a core of cement or plaster.

**Gilding of G.** Gold chloride is dissolved in boiling water: the solution is filtered, and the filtrate so far diluted, that 200 cubic centimetres contain 0.0648 gram of the metal, and it is then made alkaline with soda. The reducing agent is alcohol saturated with marsh gas; this is diluted with its own volume of water. 25 cubic centimetres of this solution are mixed with the alkaline gold chloride solution, and this mixture is poured between the perfectly well-cleaned plate to be gilded, and another sheet of glass placed at a distance of 3 mm. under the first. After two to three hours' rest the gilding is effected.

**Toughened G.** [Fr. *verre trempé*.] M. de la Bastie's process for converting ordinary into toughened, tempered, or hardened *G.*, may in general terms be said to consist in heating the *G.* to a certain temperature, and then plunging it into an oleaginous bath. For the process, however, to be successful, the observance of a number of minute details is essential; if these be neglected, failure is certain to ensue. Thus it is found, that if the *G.* be insufficiently heated it will, when immersed in the bath, fail to be affected by it, and will consequently experience no alteration in properties. Again, if overheated, it will then get out of shape; or, further, it may be heated to the right temperature, and yet be spoiled as it is being transferred to the bath. Moreover, the exact composi-

tion of the bath itself, and its temperature, constitute very important conditions, the most trifling departure from which may give rise to unsatisfactory results. All these obstacles appear to have been overcome by M. de la Bastie, who has designed plant in the shape of furnaces and baths, by means of which the tempering process can be carried out, without chance of failure. When the *G.* is brought to the required temperature, all that is necessary is that it should be plunged into the bath, and instantly withdrawn. The cost of the operation is stated to be very small. The process as carried out at New York is thus described: The *G.*, after being run from the furnaces and moulded as usual, instead of being put into annealing pans, is immersed in a hot bath consisting of three parts of flaxseed oil and one part of tallow. The bath stands at about 320°; and after remaining in this the ware is removed to a second and similar bath, by which it is cooled down to about 200°. Finally the pieces are immersed in a water bath, and then dipped into a quantity of ordinary refined burning oil. They are then cleaned, ready for packing, with plaster of Paris powder. This new process has been very much employed in the manuf. of lamp-chimneys, but the results so far obtained are variable. In some cases the articles subjected to it possess great toughness, and the *G.* bears a blow without experiencing any fracture. In other instances, however, a slight fall or blow shivers it to atoms. When the toughened glass under any circumstances breaks, it possesses a disadvantage over ordinary broken glass, in distributing itself into a great number of small, sharply angular fragments. Another process for toughening *G.*, which has been patented by Herr F. Siemens, consists in heating, and then pressing, and suddenly cooling the *G.* to be hardened; but when the articles are such as are usually moulded, the hardening and tempering are accomplished at the same time as the pressing; thus the molten glass is run into suitable moulds, and while still highly heated is squeezed, the moulds effecting the necessary cooling,—a proceeding which renders the employment of the oleaginous bath unnecessary. Mr. Bauer's method for toughening *G.* consists in heating ordinary *G.* plates so strongly that they begin to bend from softening, and then plunging them into a liquid paraffin bath having a temperature of 200°. Toughened *G.* is liable to rupture under circumstances that have not yet been accounted for.

**Soluble G.** When 8 parts of dry carbonate of soda, or 10 parts of carbonate of potash, are fused with 15 parts of pure quartz, a glass is obtained which is soluble in 6 parts of boiling water. It has been used to diminish the combustibility of wood and woven fabrics, especially of theatrical scenery; as a varnish to preserve some building stones; in fresco-painting, and in the place of rosin in the manufacture of soap.

#### Import Duties.

Glass, broken, fit for re-manufacture only, free.

" manufactures of, not otherwise provided, 40 per cent.

" plain, moulded, and pressed, 35 per cent.

" cut, engraved, colored (printed, stained, silvered, or gilded), 40 per cent.

" bottles or jars filled with sweetmeats or preserves, 40 per cent.

" crystals for watches, 40 per cent.

" plates or disks, unwrought, for optical instruments, 10 per cent.

" porcelain, or Bohemian glass, 40 per cent.

" window, rough plate, fluted, rolled, not above 10 by 15 in., 2 ct. per sq. ft.

" above 10 by 15 in., not above 16 by 24 in., 1 ct. per sq. ft.

" above 16 by 24 in., not above 24 by 30 in., 1½ cts. per sq. ft.

" above 24 by 30 in., not above 24 by 60 in., 2 cts. per sq. ft.

" window, unpolished cylinder, crown, and common, not above 10 by 15 in., 1½ cts. per sq. ft.

" above 10 by 15 in., not above 16 by 24 in., 2 cts. per sq. ft.

" above 16 by 24 in., not above 24 by 30 in., 2½ cts. per sq. ft.

" above 24 by 30 in., not above 24 by 60 in., 3 cts. per sq. ft.

" window, polished cylinder and crown, not above 10 by 15 in., 2½ cts. per sq. ft.

" above 10 by 15 in., not above 16 by 24 in., 4 cts. per sq. ft.

" above 16 by 24 in., not above 24 by 30 in., 6 cts. per sq. ft.

" above 24 by 30 in., not above 24 by 60 in., 20 cts. per sq. ft.

" above 24 by 60 in., 40 cts. per sq. ft.

" window, cast or polished, not silvered, not above 10 by 15 in., 3 cts. per sq. ft.

" above 10 by 15 in., not above 16 by 24 in., 5 cts. per sq. ft.

" above 16 by 24 in., not above 24 by 30 in., 8 cts. per sq. ft.

" above 24 by 30 in., not above 24 by 60 in., 25 cts. per sq. ft.

- Glass, window, cast or polished, not silvered, above 24 by 60 in., 50 cts. per sq. ft.
- " window, cast or polished, silvered, and looking-glass plates, not above 10 by 15 in., 4 cts per sq. ft.
- " above 10 by 15 in., not above 16 by 24 in., 6 cts. per sq. ft.
- " above 16 by 24 in., not above 24 by 30 in., 10 cts. per sq. ft.
- " above 24 by 30 in., not above 24 by 60 in., 35 cts. per sq. ft.
- " above 24 by 60 in., 60 cts. per sq. ft.

**Glass-Cloth.** See this word in the Appendix.

**Glass-Engraving.** See ENGRAVING.

**Glasses,** spectacles for assisting the sight.

**Glass-Painting,** the art of painting designs upon glass, either stained or colorless, with substances consisting usually of metallic oxides combined with a vitreous vehicle. When subjected to a great heat the colors thus applied become permanently united with the surface of the glass. Byzantine Greeks appear to have been the first persons who practised painting upon glass, and from Byzantium the art passed into the West of Europe, by way of Venice and Marseilles. In France, the art of glass-painting was practised with great success during the 12th century. After that time painted-glass windows were regarded as essential in religious edifices of any pretension. Painted windows of the 13th century abound in France, Germany, and England, and belong to the First Pointed, or Early English style of architecture. The painted glass of the 14th century was more vivid in color, with greater breadth in style, and more careful painting, than that of the preceding century. It was, however, less pure in conception, and not so strictly subordinate to the architectural effects. In the glass-painting of the 15th century a great change took place. The windows became more individualized, and still less dependent upon the architecture. The designs were larger, and began to be treated as pictures. After the 15th century glass-painting declined more and more, and until within late years has never shown any symptoms of revival. The great seats of this art are now in Munich, Nuremberg, Paris, Birmingham, and Edinburgh.

The method by which glass-painting is now practised differs in different places; but the general plan is as follows, for a small work on a single plate of glass: A careful cartoon, the size of the painting, having been procured, the glass is laid on it, a tracing made from it, and the outline is carefully traced on the glass, with black or brown, composed of a very fusible vitreous flux, colored with a metallic oxide, and ground extremely fine in an essential oil. Those parts which are intended to be yellow, orange, or red are then coated according to the tint required, with a mixture composed of an alloy of silver and antimony, ground up with the red oxide which is obtained by subjecting sulphate of iron to a red heat. The glass is then exposed in a furnace to a red heat, in which the tracing color is fused, and adheres permanently to the glass. The mixture of silver and antimony colors the glass, but does not melt; so that the oxide of iron may be brushed off in the state of dry powder, leaving the glass colored, but transparent. The other tints, composed of very fusible glass, colored with metallic oxides, are then added, and the whole once more exposed to heat. In most cases, the glass is heated, or "fired," as it is called, between the application of each color. In making a painted window, many pieces of glass are fixed together in a leaden framework, great care being taken to arrange the several compartments from the cartoon.

**Glass-Paper,** pulverized glass fastened on paper with glue, similar to emery-paper, and used like it for abrasive purposes.

**Glass-Staining.** See GLASS.

**Glass-Ware,** the commercial name for manufactures of glass, embracing plain and cut glass articles, Bohemian glass, colored, painted, and ornamented glass, bottles, etc.

**Glauber-Salts,** sulphate of soda, a compact, massive, white mineral which effloresces rapidly,

originally named after the discoverer, Glauber, a German chemist. It has a cooling, slightly bitter taste, and is a good purgative.

**Glaucous,** having a sea-green color.

**Glaze,** any coating or varnish applied to a surface to render it smooth and glassy; any facitious, shining exterior. In the porcelain and earthenware manufacture, the vitreous coating which is so essential to the beauty and utility of potter's ware. Glazes are either white or colored. The former, by the addition of the coloring ingredients used for enamels, are converted into the latter.

The best way to regard the glaze of porcelain and earthenware is as a true *glass* burnt into the surface of the ware. For coarse ware the *G.* usually contains oxide of lead; for fine ware, oxide of tin; for certain special kinds, earthy oxides. As the *G.* must not only render the ware impervious to water, but must be transparent, lustrous, and durable, its composition should bear some definite relation to that of the substance whereon it is applied; and this is attended to in practice. Metallic and earthy oxides, salt, potash, borax, baryta, phosphate of lime, silica, — all are used in some or other of the kinds of *G.* For special kinds of ware the *G.* is required to be either slightly opaque or slightly tinted; and the ingredients are selected accordingly. The chief materials in ordinary earthenware *G.* are salt and borax. The dry ingredients of the *G.* are ground to powder and mixed with water; and, in the majority of instances, the ware is simply dipped into this cold liquid. Pottery-glazing used to be an unhealthy employment when oxide of lead was much used; but borax is now substituted, producing a whiter, harder, and less injurious *G.* See PORCELAIN, POTTERY, etc.

**Glazer,** a wooden wheel for polishing knives, coated on the edge either with leather having a rough surface of emery-powder glued on, or with a ring of metal, consisting of an alloy of lead and tin. — A calenderer, or calico-smoother. — A workman who applies the vitreous incrustation to the surface of earthenware.

**Glazier,** a workman who sets panes of glass in sashes or window-frames.

**Glazier's-Diamond,** a cutting tool used by glaziers, consisting of a small diamond mounted in a handle.

**Glazier's-Point,** a small triangular piece of tin plate, used to secure a pane of glass in the sash previous to putting.

**Glazing,** the operation of putting window-panes in frames. — The operation of applying a liquid glaze on earthen or porcelain wares, or other articles. — The imparting of gloss to woven fabrics, as in calendering. — The polishing of metals by means of small wheels or disks covered with some polishing substance.

**Glengarry,** a Scotch bonnet.

**Glenlivet,** a fine kind of Scotch Highland usquebaugh, or whiskey; named from the district in which it is made.

**Glens Falls,** an insurance Co., located in Glens Falls, N. Y., organized as a mutual fire-insurance Co., in 1850, under the name of the Dividend Mutual Insurance Co., changed to a joint-stock Co., under its present name, in 1864. *Statement, Jan. 1, 1879:* Cap. stock paid up in cash, \$200,000; net surplus, \$414,931.86; risks in force, \$57,411,334; premiums, \$534,919.39; premiums received since the organization of the Co., \$3,534,488.21; losses paid, \$2,035,241.52; cash dividends paid to stockholders, \$230,300.

**Gleuconometer**, an instrument used in France to test the strength of the juice of the grape when first pressed.

**Globe**, a ball. — A glass shade for lamps. — A receptacle for small fish in a room. — A sphere, on which is represented a map or delineation of the constellations and celestial bodies, or of the parts of the earth, showing the divisions of land and water, etc.

**Globe**, a fire-insurance Co., located in New York City, organized in 1863. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$200,000; net surplus, \$127,116.16; risks in force, \$16,838,090; premiums, \$79,993.80; premiums received since the organization of the Co., \$1,466,882.27; losses paid, \$652,005.59; cash dividends paid to stockholders, \$350,000.

**Gloom-Stove**, the drying-oven used in making gunpowder.

**Glonoine-Oil**. See NITRO-GLYCERINE.

**Gloss**, a lustre or varnish; a polished or shining surface.

**Glossary**, a vocabulary explaining antiquated, local, obscure, etc., words, or scientific names.

**Glossing**, an operation consisting in moistening silk thread with steam, and stretching it to develop a gloss.

**Glossy**, having a smooth, shining surface.

**Glost-Fireman**, **Glost-Placer**, a workman engaged in the potteries.

**Gloucester Cheese**. See CHEESE.

**Glove** [Fr. *gant*; Ger. *Handschuh*; It. *quinto*; Port. *lwa*; Sp. *quante*], a well-known covering for the hand, made generally of leather, but frequently also of cotton, silk, worsted, and linen. Of the first, the finest are those made from the skin of the kid, which is valuable in proportion to its elasticity. Independent of the quality of the kid, a good *G.* is distinguished, first, by its being neatly sewed; secondly, by the thumb-seam not extending too far into the palm; and, lastly, by the color of the exterior not having soiled the inside. Most of the lower-priced *G.* offered as "kid" are in reality made of lamb-skin. When what is called kid *G.* feels unusually stout, it may be considered highly probable that it is only lamb-skin in imitation. It must consequently be understood that all good kid must be reasonably thin. The best skins are decidedly the French; next, the Italian; and, lastly, those from Ireland. *Doeskin*, though much inferior to kid, is a thick, durable, and soft leather. *Sheepskin* is chiefly used for cheap white *G.* *Buckskin* is the closest grained, and consequently the strongest leather of which *G.* are made. Its elasticity, though trifling, is sufficient. It also bears cleaning better than any other kind. It may be had in white, drab, or buff. *Tan* is of three qualities, common, drawn, and York. This is a very serviceable and cheap *G.* for gardening, riding, and driving. The strongest of each class is sewed peculiarly, and termed pricked seams. The quality of silk *G.* is determined by weight and neatness of sewing. They may be had in white, black, French white, and colors. *Thread G.* are made of hemp, and are neater in appearance, though much resembling those made of cotton. The best cotton *G.*, called *Berlin G.*, are largely manufactured in Saxony and Prussia. The silk, thread, and cotton *G.*, however, cannot be recommended, except on the score of economy. The kid *G.* of France continue to maintain their superiority over the kid *G.* of English or German make, but for inferior qualities Germany has been our principal importer. *G.* are now extensively manufactured at Gloversville, N. Y., also

in New York City, Philadelphia, Massachusetts, and Connecticut. They are made of deerskins, imported goat and sheep skins, a kind of hog-skin from S. America, and of a kip-skin of India. Most of the best sheepskin *G.* of American make, especially men's *G.*, are sold by retailers as *doj-skin G.* In 1878 the U. States imported 720,842 pairs of leather *G.*, valued at \$3,195,702. Of this total Germany contributed 343,855 pairs (\$1,403,227); France, 239,866 pairs (\$1,189,351); and England, 131,653 pairs (\$583,457).

*Manuf.* The various kinds of leather, and the various fabrics of silk, worsted, flax, cotton, etc., being prepared for, but not by, the *G.* manufacturer, whose work, which consists only in cutting out and sewing up, has been very simple since the introduction of machinery into the trade. The cutting, however, requires much tact, to get the most out of the material, and to employ the best parts in the most conspicuous places.

*Imp. duty:* Cotton *G.*, 35 per cent; cotton *G.* edged with worsted yarn, 35 per cent; Cotton *G.*, lined with wool waste, 50 cts. per lb. and 35 per cent; hair *G.*, 35 per cent; kid or leather *G.* of all descriptions, 50 per cent; knit *G.* of wool, worsted, or hair (see WOOLLENS); linen *G.*, 40 per cent; silk *G.*, 60 per cent; woollen cloth *G.* and mitts, 50 cts. per lb. and 40 per cent.

**Glove-Band**, a protection for the glove round the wrist.

**Glove-Clasp**, a kind of hook-and-eye, or stud, for fastening gloves at the wrist. — A contrivance for buttoning gloves.

**Glove-Stretchers**, instruments for opening the fingers of gloves, that they may be drawn on the hand the easier.

**Glucose**, a sugar found in many of the sweet fruits, and often seen crystallized on dried figs, raisins, etc. It is also formed from potato starch, and cellular or woody fibre, by the action of sulphuric acid. It is much less sweet than cane-sugar, and far less soluble in water, requiring 1½ parts of water to dissolve it, while cane-sugar requires only ½ part. It is used in the manuf. of beer and alcohol; for adulterating cane-sugar; and instead of gum-arabic for dressing, in weaving and printing woollens, cottons, or silks. It is also advantageously employed by paper-stainers, and for stiffening gauzes, glazing of paper, etc. In 1878 the import of *G.* into the U. States was 2,631,883 lbs., valued at \$107,218. *Imp. duty*, 20 per cent.

**Glue** [Fr. *colle*, *colle forte*], an inspissated animal jelly, or gelatine, largely employed for cementing wood, also by hatters, printers, and in the arts. The best *G.* is transparent, nearly colorless, and tasteless, has very little smell, even when melted, and is extremely adhesive. The presence of more than a trace of alum is objectionable; an undue quantity may be easily detected by the usual tests. The strongest *G.* is that obtained from skins, more especially from the hides of oxen and cows. That obtained from the bones, cartilages, and tendons is weaker. *G.* is manuf. on a large scale in various places in the U. States, and only a very small quantity of the finest kind is imported from France. *Imp. duty*, 20 per cent.

*Manuf.* *G.* is principally prepared from the parings and waste-pieces of hides and skins, the refuse of tanneries, and the tendons and other offal of slaughter-houses. These substances, when intended for the *G.*-maker, are steeped for 14 or 15 days in milk of lime, then drained, and dried by exposure to the air. This constitutes what is termed the "cleansing" or "preparation," and in this state the "*G.* pieces," as they are called, may be kept for a long time, and transported to any distance without suffering decomposition. Before conversion into *G.* they are usually again steeped in weak milk of lime, and next well washed and exposed to the air for 24 to 30 hours. They are then placed in a copper boiler two thirds filled with water, and furnished with a perforated false bottom, to prevent them from burning, and as much is piled on as will fill the vessel and rest on the top of it. Heat is next applied, and the whole

gently boiled or simmered together, until the liquor on cooling forms a firm gelatinous mass. The clear portion is then run off into another vessel, and a very small quantity of alum (dissolved) added: here it is kept hot by a water-bath, and allowed to repose for some hours to deposit its impurities, after which it is run into the "congealing boxes," and placed in a cool situation. The next morning the cold gelatinous masses are turned out upon boards wetted with water, and are cut horizontally into thin cakes with a stretched piece of brass wire, and then into smaller cakes with a moistened flat knife. The latter are placed on nettings to dry. The dry cakes of *G.* are next dipped one by one into hot water, and slightly rubbed with a brush wetted with boiling water, to give them a gloss; they are, lastly, stove-dried for sale. This furnishes the palest and best *G.* As soon as the liquor of the first boiling has drained off, the undissolved portion of skins, etc., left in the copper, is treated with fresh water, and the whole operation is repeated again and again, as long as any gelatinous matter is extracted. In this way a second and other inferior qualities of *G.* are obtained. The product from dried *G.*-pieces is about 50%. — *Hutmakers' G.* is prepared from the tendons of the legs of neat cattle and horses. It is brown, opaque, and soft, and grows moist in damp weather, but it does not render felt brittle like the other varieties. *Fish G.* is made in like manner from various membranous and solid parts of fishes (see ISINGLASS). *Parchment G.* is prepared from shreds or shavings of parchment, vellum, white leather, etc., dissolved by boiling them in water. It is scentless, and nearly colorless.

*Liquid G.* See CEMENT (CHINESE).

*Marine G.* is a very tough cement for wood, well adapted for marine and hydraulic purposes. It consists of india-rubber, coal naphtha, and shell-lac, in the proportion of 1 lb. of the first and 4 gallons of the second to a small quantity of the third. It is said that two pieces of wood cemented with this *G.* become stronger than one entire piece. This marine *G.* is also used as a substitute for pitch in paying the seams of ships.

*Portable G.* [*Fr. colle à bouche*] is made as follows: From the best pale *G.*, 1 lb.; water, quantity sufficient; dissolve in a double *G.*-pot or water-bath, with  $\frac{1}{2}$  lb. of pale-brown sugar; continue the heat until the mixture is complete, and pour it into moulds; or pour it on a marble slab, and when cold cut it into small pieces and dry them in the air. This *G.* is very useful to draughtsmen, architects, etc., as it dissolves almost immediately in warm water, fastens paper, etc., without the process of damping, and may be softened for many purposes with the tongue. When great strength is not required, 4 oz. more of sugar may be used.

**Glue-Pot**, a metal pot containing an earthenware vessel immersed in boiling water, to heat the glue in, when required to be used.

**Gluten** is one of the constituents of all kinds of ripe corn, and of many other vegetable substances. The *farina* or starch of the meal is more important in the arts; but chemists recognize a high degree of importance in the function fulfilled by gluten.

**Glutton.** See WOLVERINE.

**Glutinous**, viscid or tenacious; having the quality of glue.

**Glycerine**, a sweet sirupy liquid formed during the saponification of oils and fats. It is a colorless, odorless, uncrystallizable liquid, sweet to the taste, and of a sirupy consistence; it mixes with water in all proportions; it is unctuous and emollient, and softens bodies, like oil, but without greasing them; it does not evaporate or change in the air at ordinary temperatures, and is not susceptible of rancidity or spontaneous fermentation; it is neutral to test-paper, and possesses neither basic nor acid properties; it is easily charged with the aroma of the essential oils, and may be combined with soap, and many other substances, without undergoing change. Sp. gr. 1.27. *G.* is extensively employed in medicines, and also for a great variety of purposes other than medicinal; such, for example, as for keeping clay moist for the modeller, for preventing mustard from drying up, for keeping snuff damp, for the preservation of fruit, for sweetening liqueurs, wine, beer, and malt extracts. It is also used as a lubricant for some kinds of machinery, more especially for watch and chronometer works, because it is unaffected by contact with the air, does not thicken at a low temperature, and is without action on such metals as copper, brass, etc. *G.* is also an ingredient in copying inks. It renders printing-ink soluble in

water; indeed, it is an excellent solvent for many substances, including the Tar-colors (aniline blue, cyanine, aniline violet, and alizarine), and arsenious acid. It is also added to the pulp of paper in order to render it soft and pliable. It is said that leather driving-belts, made as they usually are of weakly tanned leather, when kept in *G.* for twenty-four hours are not so liable to fray. A solution of *G.* in water is now largely used instead of water alone for the purpose of filling gas-meters, as such a solution does not freeze in winter nor evaporate in summer. It has also been used for the compasses on board screw-steamers, in order to protect the inner compass-box against the vibrations caused by the motion of the propeller. It is also employed for the preservation of anatomical preparations, and for mounting microscopic specimens, as well as for rendering wooden casks impervious to petroleum or other oils. When treated with concentrated nitric acid, *G.* yields nitro-*G.* Even the above long list does not exhaust the many useful purposes to which *G.* is now applied. *Imp. duty*, 30 per cent.

*Manuf.* One of the best methods for preparing *G.* is as follows: Superheated steam of from 550° to 600° F. is introduced into a distillatory apparatus containing palm-oil or other fatty body. The action of the steam effects the decomposition of the fat, and *G.* and the fatty acids distil over together, but no longer in combination. In the receiver the condensed *G.*, from its higher sp. gr., sinks below the fatty acids. Sufficient steam must be supplied, and the temperature nicely regulated. The *G.* is concentrated by evaporation, and if discolored it is re-distilled. It is usually prepared with sp. gr. 1.24, and then contains 94% of anhydrous *G.* It can, however, be concentrated to sp. gr. 1.26 when it contains 98%.

**Glyphography, Galvanoglyphy**, a process to cheapen or simplify wood-engraving. A drawing is etched on a zinc plate, coated with varnish; several coats of ink are spread over the plate by a small composition-roller, being deposited only on those parts where the varnish has not been broken through by the graver. When the hollows are deep enough, the plate is placed in connection with the galvanic battery, and the result is another plate, in which the hollows of the engraving are produced in relief.

**Gnatoo**, the name in some of the Pacific islands for clothing made from the bark of the Chinese paper mulberry.

**Gnomon**, the land or style of a sun-dial.

**Go**, a slang term for a dram or glass of spirits.

**Goat**, a well-known quadruped (*Capra*), nearly the size of the sheep, to which it is allied, but stronger, less timid, and more agile; and having horns hollow, erect, and scabrous. Species of this animal are found in many parts of the world, but that which is domesticated in America (*C. hircus*) is perhaps peculiar to Europe. In the S. of Europe, particularly Spain and Italy, *G.* are more extensively reared, and flocks of them are very common. The animal is not long lived. Its young are brought forth in March or April, and two are commonly produced at a birth. It feeds on the coarsest herbage, delights to frequent rocks and mountains, and may be reared profitably in such districts as will not carry sheep. Its flesh is esteemed as food in the countries where it abounds, and the haunches are frequently salted and dried; the female is in request for her milk; the horns are useful for knife-handles; and superior candles may be made of the suet; but the part most valued is the skin, particularly that of the kid, which is extensively used in the glove manufacture. *G.*-skins are largely imported into the U. States, where they are manufactured into morocco leather. Those which are brought from Tampico, Matamoras, and Vera Cruz are worth about 20 per cent

more than those coming from Buenos Ayres. In the age of wigs the hair of the *G.* was in great request, and even yet the pure white wigs sometimes worn in England by lawyers and clergymen are made of it,—the long thick hair on the haunches being that generally preferred. The *Angora G.*, inhabiting the district around Angora and Beibazar, in Asiatic Turkey, is in high estimation for its soft and silky hair. The *Cashmere*, or *Thibet G.*, is a small, beautiful creature, greatly valued for a delicate wool procured from between its long hairs. See **ANGORA WOOL**, **CASHMERE SHAWLS**, etc. *Imp. duty*: Living, 20 per cent; hair (see **HAIR**); skins (see **SKIN**).

**Goats' Rue**, the roots of the *Galega virginiana*, used in medicine.

**Goats' Wool**. See **ANGORA WOOL**.

**Gobbing**, rubbish remaining after coal has been extracted from the coal-mine.

**Gobelins**. See **TAP-ESTRY**.

**Goblet**, a tankard, or drinking-cup.

**Go-Cart**, a small machine or frame without a bottom, running on casters or rollers, for teaching infants to walk.

**Gock**, a name in parts of Scotland for a deep wooden dish.

**Godavez**, an Indian name for the *Calamus aromaticus*, or sweet cane.

**Godron**, plaits on sleeve-ruffles, or on ladies' caps.

**Goelack**, a weight in Java, principally used for pepper, about 2 lbs.; in some parts 200 goelacks make a bahar.

**Goelette** [Fr.], a schooner.

**Goffering**, the operation of plaiting, puckering, or fluting linen, lace, etc.

**Goggles**, eye-blinds for horses.—Tubes or glazed cases in front of the eyes of a horse, to protect them from dust or intense light.

**Goglet**, a sort of pottery jar, or earthenware vase, for keeping water cool.

**Gogul**, a kind of bitumen, used in India for painting ship-bottoms.

**Gokokf**, a collective name for breadstuffs and several kinds of pulse eaten in Japan, meaning the five fruits of the field, as rice, barley, wheat, soy beans, and dried beans.

**Golah**, the Hindostani name for a warehouse.

**Gold**, the most valuable, and probably the largest known, of all the metals. From the remotest period it has been esteemed for its beauty and permanence, and has been taken as the standard measure of value amongst all civilized nations. An account of the uses of *G.* in the arts, and its influence on society in all ages, as a symbol of wealth and an article of ornament and utility, would embrace the whole history of mankind. At the present day it alike contributes to the conveniences, comforts, and luxuries of life; as often exciting the baser passions of the human heart as promoting the cause of benevolence and virtue. *G.* is of an orange-red or reddish-yellow color, and has no perceptible taste or smell. Its lustre is considerable, yielding only to that of platinum, steel, silver, and mercury. It is rather softer than silver. Its sp. gr. is 19.3. No other substance is equal to it in ductility and malleability. It may

be beaten out into leaves so thin that 1 grain of *G.* will cover 50½ sq. inches. These leaves are only  $\frac{1}{100000}$  inch thick. But the *G.* leaf with which silver wire is covered has only only  $\frac{1}{2}$  of that thickness. An ounce of *G.* upon silver is capable of being extended more than 1,300 miles in length. Its tenacity is considerable, though in this respect it yields to iron, copper, platinum, and silver. A *G.* wire 0.078 inch in diameter is capable of supporting a weight of 150.07 lbs. avoirdupois without breaking. It melts at 32° of Wedgwood's pyrometer. When melted it assumes a bright bluish-green color. Unlike the great ma-

Fig. 238. — EGYPTIAN GOLD-WORKING.  
(From the Tombs at Beni-Hassan.)

jority of the metals, it does not rust, i. e. oxidize in the air, neither does it, if pure, tarnish by exposure. In this respect it contrasts strikingly with silver, which, though indifferent to the rusting action of oxygen, is rapidly blackened by the sulphuretted hydrogen of the atmosphere. Exposed gilding tarnishes, but only because it is alloyed with silver and copper, on which this prejudicial gas can act. *G.* is readily crystallizable, and always assumes one or other of the symmetrical shapes, such as the cube, or regular octahedron, which characterizes the simplest crystallographic system. *G.* melts at a high white heat, and remains unchanged in the hottest furnaces. In the focus of a lens, however, it is vaporized by the sun's rays; and the oxyhydrogen blowpipe, or large voltaic battery, can also develop heat sufficient to volatilize it. It contracts in the act of solidifying from a state of fusion, and cannot, in consequence, be made to receive sharp impressions by casting it in moulds. Coins, accordingly, and plate are stamped or embossed, and afterwards ebasé and carved, if necessary, by cutting tools. *G.* does not dissolve in any of the ordinary acids, such as the nitric, sulphuric, hydrochloric, or acetic, but a rare acid, the selenic, can dissolve it. Its best solvent is a mixture of hydrochloric acid, with some oxidizing agent like nitric acid or oxide of manganese, which causes the hydrochloric acid to part with its chlorine. If the *G.* be in leaf, chlorine at once unites with it, and the resulting chloride is readily soluble in water. Bromine acts in the same way on the metal; and it may also be dissolved by boiling it with sulphur, potash, and water. The older chemists speculated on the possibility of Moses having dissolved the golden calf of the Israelites in this way. *G.* is also soluble in mercury, and advantage is largely taken of this property of quicksilver to dissolve the precious metal from its ores. The *G.*-amalgam resulting from the union of the metals is also extensively employed in gilding.

*G.* is, next to iron, the most widely diffused metal on the surface of the earth, but is only found in paying quantities in a few countries. It is never met with in regular veins, but in primitive or igneous rocks, or in deposits formed by the disintegration of these. In California it is chiefly found in material which has been formed by the wearing down of quartz and granite rocks. The metal is sometimes in the form of grains or flakes, or in moss-like threads, embedded in the quartz; sometimes in the form of well-defined crystals, sometimes in rough lumps, or *nuggets*. Fig. 239

Fig. 239. — GOLD IN QUARTZ.

shows three of the various modes in which *G.* is found disseminated through quartz. The soil, which has been formed by the disintegration of masses of auriferous quartz, is full of *G.*, so that a patch of such soil 12 feet square has been known to yield 30 oz. of *G.* by a very rough kind of washing to the depth of 1 ft. Soil of this kind has been carried down by rivers and streams ages ago; and the lighter particles having been carried off by the water, while the *G.*, from its greater sp. gr., remained at the bottom of the stream, the sands and gravel of these river-beds are very rich in *G.* The methods of carrying on the *G.*-seeking operations vary according to the nature of the deposit which is worked and the resources of the miner. The simplest, which was that most practised in the early days of the *G.*-fields, consists in throwing into a tub several shovelful of the surface soil, and in pouring in water while the contents of the tub are stirred about with a spade. The lighter matters are washed away, but the *G.*, by its great sp. gr., remains behind. An improvement in this, but still a very rude process, is practised by aid of the *cradle*, which is merely the trunk of a tree, hollowed out, and provided with transverse partitions and ribs. The cradle is rocked, so that the water may wash away all but the *G.* and the heavy stones. Machines for puddling by horse-power are now in use, and other contrivances have superseded the tub and the cradle in *surface washing*. The auriferous earth obtained by excavating the soil from pits is washed in a similar manner, as is also the material reached by penetrating the deeper tertiary deposits, and by driving adits or tunnels along the ancient river-beds beneath the layers of basalt. A mode of washing accumulations of auriferous earths by streams of water is employed where circumstances are favorable. A long inclined channel is constructed, and lined with boards; or, when the natural inclination of the soil requires it, a long trough is constructed and supported on trestles. The bottoms of the troughs are crossed by a number of traverse bars, which arrest the auriferous particles in their descent. The *sluice*, or series of troughs, may be from 50 feet to several thousands of feet in length, and the

cost from \$500 to \$40,000. The earth is thrown in at the upper part of the trough, and is gradually washed down, the water being allowed to flow in some cases by night as well as by day, but commonly in the daytime only, as the troughs must be watched, to see that they do not become choked up, and the soil washed out by the overflowing water. The *run* goes on for six or ten days, and then the current is stopped for a *cleaning-up*, which occupies from half a day to a day. For this operation the stream of water is stopped, and quicksilver is used to dissolve the grains of *G.* from the sand, etc., collected by the *riffle-bars*. The quick-silver is afterwards expelled from the amalgam by heat, and the gold remains as a porous mass. Sometimes, instead of shovelling the earth into the troughs, it can be washed out of its position into suitable channels by means of a powerful jet of water. This mode of working, which is termed *hydraulic jet sluicing*, offers great advantages where the natural conditions admit of its adoption. In this plan, instead of bringing the auriferous earth to the water, the water is brought to the earth

by a flexible pipe, like the hose of a fire-engine, from a reservoir about 200 ft. higher, and the stream is directed upon the material by a nozzle. This powerful jet of water is used to separate and carry away the earth to the head of a system of channels and troughs, like those already described. The hose has a diameter of 8 in., but the orifice of the nozzle, from which the water issues, is contracted, in order to increase the force of the jet. The hydraulic jet sluicing requires from three to six men to work it, and the material of a hill can be carried into the sluices in less time than a hundred persons could do it by spades. The *G.* which is embedded in quartz and other minerals, as shown in Fig. 239, is obtained by crushing the material in stamping-machines, which are usually constructed with logs of wood shod with iron. In another form of crushing-mill two large cast-iron rollers are used instead of stampers. From the crushed material the particles of *G.* are extracted by amalgamation with mercury, which is afterwards removed by distillation.

For the year 1878 the *G.* yield from all regions in the U. States was as follows, according to the figures given in the Mint Bureau report:—

California.....	\$15,260,679	Oregon.....	\$1,000,000
Nevada.....	19,546,513	Washington.....	300,000
Colorado.....	3,336,494	Dakota.....	3,000,000
Montana.....	2,289,511	North Carolina.....	150,000
Idaho.....	1,150,000	Georgia.....	100,000
Utah.....	302,000	Other sources.....	25,000
Arizona.....	540,000		
New Mexico.....	175,000	Total.....	\$47,226,107

The *G.* coin and bullion existing in the U. States October 30, 1879, was \$355,681,532, according to estimation given by the Secretary of the Treasury.

For *G.* considered as a legal tender, see *MONEY*. For the comparative quantities of *G.* produced, and the places where it is produced, see *PRECIOUS STONES*.

*Assay of G.* The quantity of *G.* in an *alloy* is usually estimated by "assaying" the sample. Before proceeding to the assay, it is necessary to form some estimate of the quantity of other metals (copper or silver, or both) in the specimen to be examined, in order to employ the proper proportion of lead in

the "cupellation." The experienced assayer commonly does this by the "assay of the touch," and, in certain cases, by a rough preliminary assay. The quantity of lead employed may be about 16 times the weight of the copper present in the sample, and when the alloy contains silver an additional allowance of lead, equal to  $\frac{1}{16}$  of its weight, is made on that account. When no silver is present, or it is not required to be estimated, a much larger proportion of lead may be employed. The weight taken for the assay ("assay pound") is usually 12 or 6 gr. The alloy and dose of lead being accurately weighed and separately wrapped in small pieces of paper, the assay may be at once proceeded with. — *Cupellation.* This operation, the most important of the whole, has been already described. Unlike silver, *G.* will bear the highest heat of the furnace without "vegetating," "fuming," or being absorbed by the cupel. The loss of weight gives the amount of copper in the alloy. — *Quartation.* The cupelled sample is fused with three times its weight of pure silver (called the "witness"), by which the *G.* is reduced to one fourth of the mass, or less, and in this state may be easily removed. — *Parting.* The alloy, after quartation, is hammered or rolled out into a thin strip or leaf, curled into a spiral form, and boiled for a quarter of an hour, in a small flask, with about  $2\frac{1}{2}$  to 3 oz. of nitric acid (sp. gr. 1.3); and the fluid being poured off, it is again boiled in a similar manner with  $1\frac{1}{2}$  to 2 oz. more of nitric acid (sp. gr. 1.2), after which the *G.* is carefully collected, washed in pure water, and dried. When the operation of "parting" is skillfully conducted, and the acid not too strong, the metal preserves its spiral form; otherwise, it falls into the state of flakes or powder. The second boiling or digestion is technically termed the "reprise." The loss of weight by "parting," after deducting that of the "witness," corresponds to the quantity of silver originally in the specimen. — *Annealing.* This consists in putting the pure *G.* obtained by the last process into a small porous crucible or cupel, and heating it to redness in the muffle. — *Weighing.* This must be done with the utmost accuracy. The weight, in grains troy, doubled or quadrupled, as the case may be, gives the number of carats fine of the alloy examined, without calculation.

*Dutch G., Mannheim, Or-molu, Pinchbeck, Prince's metal, Similor,* names applied to several varieties of fine *G.* colored brass, differing slightly in tint and in the proportions of copper and zinc. The terms tombac, prince's metal, similor, and Mannheim *G.* are used by some authors to designate alloys consisting of about 85% of copper and 15% of zinc; whereas, according to other authors, prince's metal and Mannheim *G.* are synonymous, and are composed of 75% copper and 25% zinc; according to another author, similor consists of about 71% copper and 28% zinc, and Mannheim *G.* of 80% copper and 20% zinc; and, again, according to another author, similor and Mannheim *G.* are synonymous, and are applied to alloys of copper containing from 10 to 12% zinc and from 6 to 8% tin. Seeing that such inextricable confusion exists in the employment of the terms above mentioned, it is desirable to discard them altogether. At the celebrated works of Hegermühl, near Potsdam, the proportions copper, 11 parts, to zinc, 2 parts, are employed to produce a metal which is afterwards rolled into sheets for the purpose of making Dutch *G.*-leaf. This alloy has a very rich, deep *G.* color. Its malleability is so remarkable that it may be beaten out into leaves not exceeding  $\frac{1}{100}$  inch in thickness. See DUTCH GOLD-LEAF.

*Jeweller's G.* This term is applied to alloys of *G.* used for trinkets and inferior articles of jewelry, ranging from 3 or 4 carats fine upwards. The lowest alloy of this class is formed of copper, 16 parts; silver, 1 to  $1\frac{1}{2}$  parts; *G.*, 2 to 3 parts; melted together. This is worth only from \$2.15 to \$2.85 the oz. It has recently been found that *G.* of the quality of 12 carats, or less, if alloyed with zinc instead of the proper quantity of silver, presents a color very nearly equal to that of a metal at least  $2\frac{1}{2}$  to 3 carats higher, or of \$2 to \$2.75 an ounce more value; and the consequence has been that a large quantity of jewelry has been made of *G.* alloyed in this manner; and the same has been purchased by some traders, very much to their own loss as well as that of the public; inasmuch as a galvanic action is produced, after a time, upon *G.* so alloyed, by means of which the metal is split into several pieces, and the articles rendered perfectly useless.

*Trichloride of G.*, a substance consisting of 1 part *G.* dissolved by aid of heat in 8 parts of nitro-hydrochloric acid, and evaporated down to near dryness, and allowed to crystallize in orange-red needles, or ruby-red prismatic crystals. It is deliquescent; soluble in water, ether, and alcohol, forming a deep-yellow solution. It is employed in medicine, but its most important use is as a reagent in photography, large quantities being manufactured for use as a chief agent in toning photographic prints. To some extent it is also used for electro-gilding; and, mixed with excess of bicarbonate of potassium, it forms a good yielding solution for small articles of copper. These are to be first cleaned with dilute nitric acid, and then boiled for some time in the mixture. The above is the salt generally referred to under the name of the *chloride of G.*, or in commerce occasionally as the *mariate of G.*

*Imp. duty:* *G.* bullion and coin, free; *G.* jewelry, 25 per cent; *G.*-leaf, \$1.50 per package of 500 leaves. See, besides, the names of articles made of *G.*

**Gold-Amalgam**, a yellowish white mineral which is a mixture of gold and quicksilver.

**Gold-Beater**, a hammerer of gold into leaves or sheets. See GOLD-LEAF.

**Gold-Beater's Mould.** See GOLD-BEATER'S SKIN.

**Gold-Beater's Skin** is one among many forms of thin membrane useful in the arts. It is made from the intestine of the ox, which is scraped to remove the fatty matter; then turned inside out in order to be scraped and washed on both surfaces; then left to ferment to loosen the mucous and peritoneal membranes; then scraped against a blunt edge to remove these membranes. After various scrapings and cleansings in alkaline solutions, two membranes are placed together, with the mucous surfaces in contact; and each pair, after various processes of steeping, beating, pressing, and drying, in which solutions of alum and white of egg are employed, form one sheet or leaf of gold-beater's skin, — a thin but tough and very peculiar substance. It is used for medical and various other purposes, but chiefly by the gold-beater (see GOLD-LEAF). A mould of gold-beater's skin contains 800 to 1,200 leaves, about  $5\frac{1}{2}$  inches sq. It is said that 500 oxen yield only enough of this peculiar membrane to make one mould of 800 leaves. The making of this substance is a dirty and repulsive trade, but the product in the form of a mould of leaves is worth from \$40 to \$50: *Imp. free.*

**Gold-Beating.** See GOLD-LEAF.

**Gold-Burnisher**, a workman who polishes and brightens articles made of gold.

**Gold-Caster**, one who moulds, or runs, gold into different shapes and articles.

**Gold-Chaser**, a workman who embosses gold.

**Gold-Cloth**, a cloth of gold wire.

**Gold-Coinage**, the current gold coins of the country. See DOLLAR, EAGLE, and also MONEY.

**Gold-Cutter**, a workman who prepares gold for the use of others.

**Gold-Digger**, a seeker for gold.

**Gold-Dust**, gold ore met with in fine grains or particles of gold, as washed from the earth and clay in the gold-fields.

**Golden**, made of gold; of the color of gold.

**Golden-Yellow**, a pigment of sulphur of antimony, which produces an orange-yellow.

**Gold-Field**, an auriferous deposit and diggings in a locality where gold is found.

**Gold-Fish**, a small ornamental species of carp, *Cyprinus auratus*, which is kept in tanks, globes, or ponds, for their beauty and gentleness.

**Gold-frame Maker**, a manufacturer of gilt picture and looking-glass frames.

**Gold-Lace** (more properly *gilt-lace*), a thin covering of gold applied to a surface of silver, which again has a foundation of silk. The silken threads for making this material are wound round with gold wire so thickly as to conceal the silk; and the making of this gold wire is one of the most singular mechanical operations imaginable. In the first place, the refiner prepares a solid rod of silver, about an inch in thickness; he heats this rod, applies upon the surface a coating of gold-leaf, burnishes this down, applies another coating, burnishes this down, and so on, until the gold is about one hundredth part the thickness of the silver. Then the rod is subjected to a train of processes which brings it down to the state of a fine wire; it is passed through holes in a steel plate, lessening step by step in diameter. The gold never deserts the silver, but adheres closely to it, and shares all its mutations; it was one hundredth

part the thickness of the silver at the beginning, and it maintains the same ratio to the end. It has been calculated that the gold on the very finest silver wire for gold-lace is not more than *one third of one millionth part of an inch* in thickness; that is, not above one tenth the thickness of ordinary leaf-gold. — In the original method of gold-lace making, a stiff thread was produced, long used for making cloth of gold, etc., but manufacturers have been enabled to apply gold to flexible thread by means of recent inventions. The process of coating flexible threads with gold film is called *fibre-gilding*. Chemists and manufacturers have long tried to overcome the many difficulties which stand in the way of fibre-gilding, and all the chemical and metallurgical processes have been successively tried; but although it was found easy to attach the gold to the thread, yet the whole was too long in drying, and had too soft a foundation, to admit of burnishing. The brilliancy of gold-lace produced by fibre-plating has never been surpassed or even imitated by any of the processes invented. Among the principal methods in use are the chemical processes of Mr. Albert Hock and Mr. Green, and that of Dr. Krong of Stolberg. Electro-metallurgy has not been rendered directly applicable; but by M. Barot's method, the material to be gilt is dipped in a solution of nitrate of silver and ammonia. After remaining two hours, and dried, it is exposed to a current of pure hydrogen gas. A silvered surface is thus produced, which can easily be gilt by the electro-metallurgic process.

**Gold-Leaf**, an extremely thin tissue of gold, prepared by beating the gold metal until the requisite degree of fineness has been obtained. It is found that a minute percentage of silver and copper is necessary to give the gold for gold-leaf a proper malleable quality, — a percentage of perhaps one in 70 or 80. The refiner manages this alloy, and brings the costly product to a certain stage of completion; he melts the gold and the cheaper alloys in a black-lead crucible; he pours the molten metal into an ingot mould, six or eight inches long; he removes the solidified and cooled ingot from its mould, and passes it repeatedly between two steel rollers until it assumes the thickness of a ribbon; and this ribbon, about one eight hundredth of an inch in thickness, and presenting a surface of about 500 square inches to an ounce, passes next into the hands of the gold-beater. — The ribbon being cut into inch-square pieces, 150 of these are interleaved with thick paper, and enclosed in a parchment case called a *cutch*. The cutch is subjected to a long-continued series of blows, administered to all parts of both surfaces equally with a 16-lb. hammer which has two somewhat rounded faces, on a smooth marble slab. When each gold piece has been stretched out by this beating to 4 sq. in., the cutch is opened, the pieces are cut into four of 2 sq. in. each, and these are interleaved in a book of gold-beater's skin called a *shoder*, the 150 pieces being now 600. Another beating with a 9-lb. hammer spreads out these as before, and another cutting augments the number from 600 to 2,400. These are separated into three packets of 800 each, and each of these packets is again beaten in a book of gold-beater's skin called a *mould*; this beating, lasting four hours, is with a 7-lb. hammer. The leaves of gold, now reduced to the proper thickness, are cut with smooth wooden knives into  $3\frac{1}{2}$  sq. in.; twenty-five of these leaves are interleaved in a book, the paper of which has been rubbed over with red chalk to prevent adhesion; and four such books, contain-

ing 100 leaves of gold, are worth about \$1.25. According to the tint, the gold obtains the technical names of fine, red, pale red, deep orange, lemon, pale, party, white, etc. Gold-leaf is the thinnest substance produced in the mechanical arts, being only  $\frac{1}{250,000}$  of an inch in thickness. A medium kind is made of 42 parts pure gold, 12 silver, and 6 copper. Silver-leaf and copper-leaf, and mixtures of the two, can be beaten out, but not to such an excessive thinness as gold-leaf. *Dentists'* gold is thicker than ordinary gold-leaf, being carried no further in the process than that of the cutch. It should be perfectly pure gold. *Imp.* duty, \$1.50 per package of 500 leaves.

In beating gold, the dryness of the cutch, shoder, and mould is a matter of extreme delicacy. They require to be hot-pressed every time they are used, although they may be used daily, to remove the moisture which they acquire from the atmosphere, except in extremely frosty weather, when they acquire so little moisture that then a difficulty arises from their over-dryness; the brilliancy of the gold is diminished, and it spreads very slowly under the hammer. On the contrary, if the cutch or shoder be damp, the gold will become that which is technically termed hollow or sieve-like; that is, it is pierced with innumerable small microscopical holes; and in the moulds in its more attenuated state it will become reduced to a pulverulent state. This condition is more easily produced in alloyed golds than in fine gold. It is necessary that each skin of the mould should be rubbed over with calcined gypsum (the fibrinated variety) each time the mould may be used, in order to prevent the adhesion of the gold to the surface of the skin in the process of beating.

**Gold-Mounter**, one who ornaments, frames, or sets articles in gold.

**Gold of Pleasure**, the *Camelina sativa*, a plant much cultivated in Europe for its seeds, which produce a fine oil; the stems also yield a coarse fibre used for making sacks, sail-cloth, and coarse packing-paper, and are employed for thatching.

**Gold-Paper**, a fancy paper, the surface of one side of which is covered with a gold-size.

**Gold Pen**. The manufacture of pens of elastic material furnished with durable points of some extremely hard substance began in England with attempts to secure bits of metal to pens made of glass, tortoise-shell, and horn. This finally led to the production of gold pens, the manufacture of which is carried to the highest perfection in New York, the best pens being made here and sent to Europe and other parts of the world. In 1823 John Isaac Hawkins, an English engineer, embedded pieces of diamond and ruby in the points of tortoise-shell pens, which were softened in water to receive the stones. The same manufacturer, hearing that bits of an extremely hard native alloy of iridium and osmium, sent by Dr. Wollaston to a penmaker to be used for points, had been returned as too hard for working, obtained these for his own experiments, and was the first to produce the famous "diamond points" soldered to gold pens. The right to make gold pens was purchased of Mr. Hawkins by Mr. Cleveland, an American clergyman then in England, who on his return, in 1835, induced Levi Brown, a watchmaker in Detroit, to undertake their manufacture. The experiment was attended with little success. Mr. Brown removed in 1840 to New York, and there introduced the business, which gradually increased in importance as the quality of the pens was improved, and the price diminished by their more rapid production. At first the pens were cut with scissors from a thin flat strip of gold, and a slit being cut in the nib a bit of iridium was soldered to each point separately, and the points were then rounded up into shape with a mallet upon a stick. The inferior pens thus made by hand sold for \$5 to \$10 each. The first machines, and almost the only important ones in use applicable to the differ-

ent branches of this work, were invented and first manufactured by Mr. John Rendell in 1844. Mr. Bagley systematized the process, giving to each workman his peculiar branch, and thus nicety and certainty of good work were attained. Great improvements have been introduced, and active competition, with an extensive demand, has resulted in the production of perfect gold pens at less than one half the early price.

Different manufacturers have different modes of operation, but the following will give a general idea of the perfected method employed in the large and old establishment of Messrs. Mable, Todd, & Bard, at New York: Sheet or plate gold, about  $\frac{3}{16}$  of an inch in thickness, is cut by means of a lever-press with die set into stubs, or small pieces, each piece having a point at one end. A machine then indents the point for the reception of the nib, and a small particle of iridium is fastened to the golden point with a flux and sweating the gold, which makes the pen much more durable than it was when a solder was used. The gold, after being hammered to give it elasticity, is cut to the proper shape with a die, stamped with the manufacturer's name and any other device, and turned up to the rounded quill-like form. This is made by the "raising-up machine," a screw press of great power, with many parts and very expensive fittings. The iridium is then split into a nib by a rapidly revolving copper disk, and another machine extends the slit into the gold. The point is ground on revolving copper wheels, which is the most important part of the manufacture, the skill of the grinder making the writing quality of the pen either coarse or fine. After grinding, the finished pen is finally polished. Thus prepared, a gold pen is everlasting; the gold resisting the corrosive action of ink, while the iridium point will bear an infinite amount of work without wearing away. *Imp. duty, 40 per cent.*

**Gold Plate**, dishes or table service of gold.

**Gold-Printer**, a printer who does ornamental printing, letter-press, or lithography, in gold.

**Gold-Shell**, or **Shell-Gold**, used in painting and illuminating, is made by grinding gold leaves with honey, and afterward separating the honey from the powdered gold by means of water. When the honey is washed away, the gold may be put on paper or kept in shells. When used, it is commonly diluted with gum-water. The German gold-powder, prepared in this manner from the Dutch gold-leaf, is generally used; and when it is well secured with varnish, it answers the end in japaners' gilding tolerably well.

**Gold-Size**, a kind of gold-paint or thick tenacious varnish used for burnished gilding. It is prepared of  $1\frac{1}{2}$  pounds of pipe-clay,  $\frac{1}{2}$  an ounce of red chalk,  $\frac{1}{2}$  of an ounce of black lead, 40 drops of sweet oil, and 3 drams of pure tallow. The clay, chalk, and black lead are to be ground very fine, separately, in water, then mixed together; the oil and tallow are next added, and the mixture is ground to a due consistence.

**Goldsmith**, one who manufactures vessels and ornaments of gold and silver; a manufacturing jeweller.

**Gold-Thread**, thread used for embroidery, consisting of flattened silver-gilt wire closely twisted, or wrapped over a thread of yellow silk by machinery.

**Gold-thread Root**, a name for the roots of some species of *Coptis*. In the U. States, the root of *C. trifoliata* is a popular remedy for aphthous affections of the mouth in children. In India, the golden thread root of *C. teeta* of Assam, which is intensely bitter, brings a very high price, being deemed a tonic remedy of the greatest value.

**Gold Wire** is made by taking a cylindrical ingot of silver which has been superficially coated with gold, and drawing it successively through a series of holes in a hardened steel plate, each of which is a degree smaller than the preceding hole, and proceeding thus until the requisite degree of fineness is attained. It may be observed that in this process, however fine be the wire, its gilded

surface exhibits no flaw, even when viewed by the microscope. *Flattened gold wire* is the same wire after it has been passed between rollers of polished steel.

**Goloe-Shoes**, an overshoe of caoutchouc or leather for keeping the feet dry, generally called *goloshes*.

**Golpathen**, an Indian striped silk.

**Golsch**, a name in Württemberg for a piece of cloth measuring 72 aunes, or ells.

**Golt-Shut**, a gold or silver ingot.

**Gomastah**, a native factor, or agent, in the East Indies.

**Gombo, Gumbo**, the *Hibiscus cannabinus*, a plant of the order *Malvaceæ* (Fig. 240), which

Fig. 240.—GOMBO PLANT.

yields a strong fibre. From its pod a soup is made in Louisiana.

**Gome**, grease for cart-wheels.

**Gomeh**, in India, a handful; literally, as many rice-stalks, with ears attached, as can be grasped by the hand.

**Gomelin**, a kind of German dextrine (starch from potatoes), in crystals and in powder, used as weavers' glue for cotton warps, and for dressing printed calicoes.

**Gomuti**, or **Ejoo**, a species of palm (*Borassus gomutus*) growing in the Indian islands. A valuable product is obtained from this palm, resembling *black horse-hair*; it is found between the trunk and branches, at the insertion of the latter, in a matted form, interspersed with long, hard, woody twigs of the same color. When freed from the latter, it is manufactured by the natives into cordage. Its fibres are stronger and more durable, but less pliant, than those of the cocoa-nut, or coir, and it is, therefore, fitter for cables and standing rigging, but less fit for running rigging. The native shipping of the eastern islands of all kinds are chiefly equipped with cordage of the G.; and the largest

European shipping in the Indies use cables of it. It undergoes no preparation but that of spinning and twisting; no material similar to our tar and pitch, indispensable to the preservation of hempen cordage, being necessary with a substance that, in a remarkable degree, possesses the quality of resisting alternations of heat and moisture. The *G.* of Amboyna and the other Spice Islands is the best. That of Java has a coarse ligneous fibre. *G.* is generally sold in twisted shreds, or yarns, often as low as one dollar a picul, and seldom more than two.

**Gonakie Gum**, a bitter variety of Senegal gum.

**Gonaives**. See HAYTI.

**Gondola**, a kind of barge used chiefly on the canals of Venice, where gondolas supply the place of carriages. The *G.* is flat-bottomed, very long and narrow (averaging about 30 feet by 4), and its two sharply pointed extremities are curved upward to the full height of a man. It is also provided with a small chamber placed near its centre, and elevated to a convenient height above the line of the gunwale. It is propelled by oars or a pole by the gondolier, who stands at the stern.

**Goneometer**, an instrument for measuring the angles of crystals.

**Gong**, a Chinese musical instrument of percussion, formed entirely of metal, which yields a very loud and peculiarly harsh sound when struck with force. It is made of an alloy of 25 parts of tin and 100 parts of copper, and in form it nearly resembles the common tambourine. *G.* are much used in China for making loud sonorous signals, particularly on the canals, as well as for adding to the clangor of martial instruments.

**Gongonah**, a variety of maté, or Paraguay tea, used in Brazil, prepared from the leaves of *Ilex gongonah* and *I. theezans*, species of holly.

**Gonje**, a small weight used in India for precious metals, nearly two grains.

**Good Hope (Cape of)**. See CAPE OF GOOD HOPE.

**Goods**, a general name for movables, but usually restricted to merchandise; heavy traffic; property; wares.

**Goods-Train**, the English term for a railroad freight-train.

**Good-Will**, the custom of any business or trade; that interest in it which is sold along with the goods and premises. By disposing of the good-will, the seller binds himself to do everything in his power to advance the interests of his successor in the business, and to recommend him to his customers. It is also usual to specify that the seller shall not enter upon the same business within a certain distance of that which he has sold. Such a contract is good at law, and the party infringing it is liable in damages.

**Googul**, a resinous substance resembling myrrh, met with in India, believed to be the bdellium of commerce, and probably the produce of *Commiphora Madagascariensis*.

**Goolcund**, a conserve flavored with roses, made in the East.

**Goolo**, a pottery vessel made in the Feejee islands.

**Goondooming**, a seed or bead used in some parts of the East as a weight for gold and silver; three of these make one canteroy, or fanam, which is about 5.875 grains.

**Goor**, a name in India for coarse or half-made sugar; the concentrated sirup or juice of the date-palm (*Phoenix dactyliferus*). It is also called jagery; 12 pints of the sap are boiled down to 1

of goor, and 4 of goor yield 1 of good powder sugar.

**Goose**, a genus of web-footed birds; the tame *G.* (*Anser domesticus*) is well known, and is largely reared for its flesh, quills, and feathers. Wild geese in the winter are sometimes brought to market. — A tailor's smoothing and pressing-iron.

**Gooseberry**, the fruit or berry of *Ribes grossularia* and *Ribes uva-crispa*, of which there are several varieties. This fruit, when ripe, is wholesome and slightly laxative. The juice of the unripe fruit is made into wine called *English champagne*. *G.* are preserved by simply bottling them, and keeping them in a very cold place.

**Goose-Grass**, the *Gallium aparine*, a plant common in Europe and America, the expressed juice of which is variously prepared in medicine, and the herb itself is used in the form of ointments or decoctions.

**Goose-Neck**, on shipboard, an iron ring fitted at the end of a yard or boom, for various purposes. — A nozzle having a universal-joint connection to the stand-pipe of a fire-engine.

**Goowa**, the Bengalee name for the betel-nut, *Arecia catechu*.

**Goracco**, prepared tobacco; a paste smoked in their hookahs by the natives of Western India. The tobacco having been cut very fine, molasses, cinnamon, musk, and other aromatics and perfumes are added, until the mass assumes the form of an electuary.

**Gordonia**. See LOBLOLLY BAY.

**Gore**, a narrow strip of any fabric to let in to another piece. — An angular or oblique piece of canvas which increases the breadth or depth of a sail.

**Gorgerette** [Fr.], a woman's kerchief.

**Gorgonelle**, a Dutch cloth.

**Gorse**, another name for furze or whin.

**Goslanite**, a name for sulphate of zinc, use in medicine and in dyeing.

**Gossamer**, a very thin gauze, or finely woven siken web.

**Gotah**, an Indian name for tissues.

**Gottenburg**. See SWEDEN.

**Gouge**, a semi-circular, hollow, scooping chisel, for making a rounded groove in cutting or turning wood. — In bookbinding, a finisher's hand tool having a curved face, and used for blind-tooling and gilding.

**Gouge-Bit**, a bit in the form of a carpenter's gouge, used for boring wood.

**Gouge-Slip**, oil-stone, or hone, with rounded edges, for sharpening gouges.

**Goulard's Extract**, a solution of acetate of lead, used as an external lotion.

**Gourde**, a name given to the colonial dollar in the West Indies, and in Louisiana to the American dollar.

**Gourds**, cucurbitaceous plants, several of which have commercial uses. The bottle or trumpet *G.*, and the colocynth *G.*, have already been mentioned. The squash *G.* (*Cucurbita melopepo*), and the common *G.*, or pumpkin (*C. pepo*), are agreeable culinary fruits, and used for making pies. The vegetable marrow is a variety of the common *G.* The very large Indian *G.* (*C. maxima*) is met with in gardens under the French name of *Fatoon jaune*, and used in soups or mashed. The young fruit of the *G.* are used for pickles.

**Goureau**, a kind of long, violet-colored fig; Madona fig.

**Gouze**, a name in Bombay for the grain weight, used in weighing gold or silver; the 100th part of a tola.

**Governor**, one who directs. — That part of a steam-engine which regulates the supply of steam from the boiler to the cylinder, and insures the nearly uniform velocity of the piston. The mode in which this is accomplished may be seen in Fig. 241, which represents the favorite form of *G.* *D* is a vertical axis carrying the pulley, *l*, which receives a rotary motion from the driving-shaft of the engine, by a band not shown in the figure. Near the top of the axis, at *e*, two bent rods work on a pin, crossing each other in the same manner as the blades of a pair of scissors. The two heavy balls are attached to the lower arms of these levers, which move in slits through the curved guides intended to keep them always in the same vertical plane as the axis, *D*. The upper arms are jointed at *B B* to rods linged at *H H* to a ring not attached to the axis, but allowing it to revolve freely

Fig. 241. — STEAM-ENGINE GOVERNOR.

within it. To this ring, at *P*, is fastened one end of the lever connected with the throttle-valve in a manner sufficiently obvious from the cut. The position represented is that assumed by the apparatus when the engine is in motion, the disk-valve, *A*, being partly open. If from any cause the velocity of the engine increases, the balls diverge from increased centrifugal force, and the effect is to draw down the ring at *P*, and, through the system of levers, to turn the disk in the direction of the arrows, and diminish the supply of steam. If, on the other hand, the speed of the engine is checked, the balls fall towards the axis, and the valve is opened wider, admitting steam more freely, and so restoring its former speed to the engine.

**Gowland's Lotion**, the essential oil of bitter almonds, mixed with sugar, spirits, and corrosive sublimate.

**Gown**, a woman's long outer garment. — A man's official loose robes, or dressing-wrapper.

**Gown-Piece**, enough material for a dress.

**G. P. O.**, abbreviation for General Post-Office.

**Grab**, an implement varying in form, but essentially consisting of a pair of serrated jaws, used for withdrawing pipes, drills, etc., from artesian, oil, and other wells which are drilled, bored, or driven.

**Grace**. See DAYS OF GRACE.

**Graddan**, a kind of Scotch snuff.

**Grade**, quality, as different grades of flour, wheat, or coffee. See GRADIENT.

**Gradient**, **Grade**, the actual acclivity or declivity upon a railroad, which affects the speed at which a train can travel; as a *G.* of 3°, a *G.* of 42 feet per mile, a *G.* of 2 feet on 330.

**Gratine**, a toothed chisel used by sculptors.

**Graduated Bottle**, a bottle having horizontal marks, blown, pressed, or cut on its side, to indicate quantity of contents at given levels.

**Graduation**, the placing of measuring marks

on an instrument of any kind, which often requires the highest refinement of mechanical art. A carpenter's rule, with the inches divided into eighths, may be taken as a type of such dividing or graduating as can be easily effected to the requisite degree of accuracy. A mural quadrant for an observatory, in which the  $\frac{1}{1000}$ th part of an inch is regarded as a serious quantity, is the type of a wholly different kind, in which eyesight and mechanical delicacy are taxed to the utmost. The substances operated upon are box, larch, and one or two other kinds of wood, and ivory, brass, platinum, silver, gold, etc. In a few cases the *G.* marks are painted on the surface; but more usually they are engraved or incised. The more delicate *G.* are upon circles or portions of circles for quadrants, sextants, theodolites, transit instruments, equatorials, mural circles, rather than upon straight-line measurers. The graduator or divider is provided with pattern plates, rings, straight-edges, and other guides of similar kind. There are machines, called *dividing engines*, employed in the more delicate examples of *G.*, on which the utmost skill of such men as Ramsden, Troughton, Simms, and Ross has been displayed. Special *G.*, of great fame, are Froment's electro-divided lines, 25,000 to an inch; Nobert's lines on glass, 57,000 to an inch; and Whitworth's matchless micrometer, measuring a space of one millionth of an inch! The last named, however, measures by screw-threads, not by *G.*

**Graduator**, a vessel for accelerating the formation of vinegar by arrangements to diffuse the liquid over a large surface, so as to secure rapid acetification, in consequence of exposure to the air.

**Graefenberg**. See GERMANY (WINES OF).

**Grafting**, covering a rope by weaving together yarns. — The process of inserting a shoot or scion of one tree into the bark of another, to make it yield fruit. — Knitting new feet to stockings.

**Grah**, an Indian long measure; in Guzerat, the sixteenth part of the guz, and rather more than two inches.

**Grailing**. See COMB (MANUF. OF).

**Grain**, a single seed of any cereal plant which is used for food. This word, however, is more generally used collectively for the fruit or seed of cereal plants in general, as wheat, Indian corn, rye, barley, etc.; as a cargo of *G.*, a *G.*-market. The principal *G.*-markets in the world are Chicago, Buffalo, Odessa, Baltimore, Galatz and Braila, Archangel, Dantzic, St. Petersburg, Oswego, etc.

The smallest weight in common use in this country and England; the  $\frac{1}{7000}$ th part of a lb. avoirdupois, and the  $\frac{1}{5760}$ th part of a lb. troy; in apothecaries' weight the 20th part of a scruple; in troy weight the 24th part of the penny-weight. The grain for diamonds is only 0.79 gr. In France the grain for pearls is 0.80, and for precious stones, 0.79.

The direction of the fibres in wood and other fibrous substances. — The word is applied in dyeing to a thorough dye; as "goods dyed in the grain," which is to say, that the raw materials or fibres were dyed before manufacture.

**Grain-Cleaner**, a winnowing machine.

**Grain-Dryer**, a machine or contrivance, of which there are several kinds, for drying damp grain, or kiln-dry grain in sound condition, so as to fit it for ocean shipment. The revolving-cup dryer (Fig. 242) consists of a chamber filled with an ascending current of heated air. The grain, passing through a heated cone seen at top of the chamber, falls on a revolving flanged disk which

distributes it to be again collected by a hopper, fed to another cup, and so on down through to the discharge-spout.

**Grained**, painted in imitation of the grain or fibres of certain woods.

**Grainer**, a workman who ornaments wood-work with fancy devices; the brush with which he

Fig. 242. — GRAIN-DRYER.

works. — An infusion of pigeons' dung in water, used for giving flexibility to skins in the process of tanning. — A knife used by tanners and skinners for taking off the hair from skins.

**Graining**, a process in tanning which consists in rubbing the leather on the flesh-side with a pommel, as to give it a granular appearance and render it supple. — A method of painting in which the grain or fibres of wood are imitated.

**Grain-Leather**, a name for dressed horse-hides. — Goat, seal, and other skins, blacked on the grain-side for women's shoes, etc.

**Grains**, the refuse or husks of malt from a brewery, or of any grain after distillation; usually purchased to feed cows and pigs with. — A kind of iron harpoon, with four or more barbed points to it, used for striking small fish.

**Grains of Health** [*grains de sante du docteur Franck*] are silvered pills, containing 1 part gamboge and 4 parts aloes.

**Grains of Paradise**, the aromatic pungent seeds of the Malaguetta pepper (*Annonum grana Paradisi*) obtained on the coast of Guinea; a spicy condiment, used in veterinary practice, and in the illegal preparation of malt liquors, etc. *Inp.* duty, 20 per cent.

**Grain-Tin**, crystalline tin ore; metallic tin, smelted with charcoal; the purest kind of metal, that reduced from the loose grains of tin stone.

**Graip**, a dung-fork; a tool for lifting or digging potatoes from the ground.

**Graith** [*Sc.*] the furniture of a house; accoutrements of a horse; apparatus of any kind; wearing apparel.

**Gram**, a common name in India for several kinds of pulse, the produce of varieties of *Dolichos* and *Phaseolus*.

**Gramashes**, garters reaching to the knees. — A kind of stockings worn in Scotland instead of boots.

**Gramigna**, a name in Italy for the long underground shoots of couch grass (*Triticum repens*), which is extensively collected after the plough and harrow, and used as food for horses.

**Gramme**, the proper unity of French weight, a cube of one hundredth of a metre on a side, and equal to 15.4339 troy grains. The kilogramme, which is the weight of a cubic decimetre of pure water, is, however, practically used as the unity of weight in France.

**Gramola** [*It.*] an instrument for beating or bruising flax.

**Gram-Pot**, a boiler in which pulse is cooked by the natives in India.

**Granada**. See NICARAGUA.

**Granadilla**, a climbing plant of the tropics, *Passiflora quadrangularis*; the subacid pulp of the fruit is esteemed, and the root is emetic and narcotic.

**Granary**, a warehouse or place where corn is stored.

**Grande**, in a sugar manuf., the largest evaporating pan of a battery.

**Grand Haven R.R.** runs from Allegan to Muskegon, Mich., 57.5 m. This Co., whose offices are in Allegan, was organized in 1869 as the Michigan Lake Shore R.R. Co. In 1875 it was placed in the hands of a receiver, and in 1878 it was sold under foreclosure and reorganized under its present title. *Financial statement*: Cap. stock, \$800,000; receiver's certificates, \$160,000; total, \$960,000.

**Grand-Jury**, the first or principal jury, to which is referred the examination of indictments against criminals.

**Grand-Piano**, a long piano-forte, shaped like a harpsichord.

**Grand Rapids and Indiana R.R.** runs from Fort Wayne, Ind., to Petoskey, Mich., 332 m. This Co., whose offices are in Grand Rapids, Mich., has leased for 99 years the Cincinnati, Richmond, and Fort Wayne R.R., 91.5 m. in length, guaranteeing interest on the bonds of that Co. It has also leased the Allegan & Southeastern R.R., 11.50 m., for the net profits of the line, and operates the Traverse City R.R., 26 m. in length, making a total of 461.1 m. under its control. *Financial statement*: Cap. stock, \$2,800,000; funded debt, \$8,000,000, as follows: 1st mortgage, land-grant bonds, guaranteed, issued 1869, \$4,000,000 payable 1899, interest 7% (Jan. and July); 1st mortgage, land-grant bonds, unguaranteed, issued 1869, \$3,205,000, payable 1899, interest 7% (April and Oct.); income bonds, issued 1875, \$795,000, payable 1906, interest 7%. The Co. holds two land-grants amounting to 1,160,000 acres, of which 852,960 acres have been certified.

**Grand Rapids, Newaygo, and Lake Shore R.R.** runs from Grand Rapids to White Cloud, Mich., 46 m. This Co., whose offices are in Grand Rapids, was organized in 1869 and completed in 1875. *Financial statement*: Cap. stock, \$533,000.84; funded debt, \$776,000, as follows, — 1st mortgage, 8% 20-year bonds, issued 1871, \$560,000; and 2d mortgage, 7% bonds, payable in 1905, \$149,500 of which are held by the Co.

**Grand River Valley R.R.** runs from Jackson to Grand Rapids, Mich., 82.4 m. This Co., whose offices are in Jackson, Mich., was chartered in 1846, and the road, completed in 1870, is leased to the Michigan Central R.R. Co. Interest on its bonds and a dividend of 5% on its paid-in stock

are paid by the Michigan Central. *Financial statement*: Cap. stock authorized, \$1,000,000; paid in and guaranteed 5%, \$492,000; funded debt, \$1,500,000, as follows: 1st mortgage, 8% bonds (assumed by Michigan Central), \$1,000,000, payable 1886; and 2d mortgage, 8% bonds (guaranteed by lessees), \$500,000; total stock and bonds, \$1,991,200. Cost of road, \$2,840,031.

**Grange**, a farm having suitable barns, stables, and other necessary buildings for stock, etc.

**Granilla**, a small inferior variety of cochineal.

**Granite**, a plutonic or igneous rock, consisting of quartz, mica, and felspar. *G.* is one of the most valuable of building-stones. The hard, close-grained varieties are the most durable. It should be pure from pyrites or any ore of iron. By examining the rock in its native beds, good evidence can be obtained as to its durability. The more felspathic are less enduring than the quartzose, and the syenitic or hornblende variety is the most durable. *G.* is capable of sustaining an immense pressure, which makes it peculiarly valuable for large works or buildings. Experiment has demonstrated that a weight of 24,556 lbs. is required to crush a half-inch cube of the best stone. *G.* abounds in New England. Excellent *G.* is quarried in Maine, Virginia, and New Hampshire, but the most celebrated quarries are in Massachusetts. The Quincy *G.* is properly a syenite. *G.* is detached in blocks of any length by drilling holes every few inches in the line of desired fracture, and driving in wedges of iron between steel cheeks, or half-round pieces fitting the sides of the hole. After removal the rock hardens somewhat, and is less easily cut than when first taken from the quarry. *Imp. duty*, \$1.50 per ton; dressed or polished, 20 per cent.

**Granulated**, formed in small grains, as in sugar, grain tin, etc.

**Granulation**, the act or process of forming, or breaking into, grains or small masses.

**Pharmacy**. The *G.* of medicine has of late years received considerable attention from both foreign and American pharmacutists. In France, granulated powders (*poudres granulées*) are coming into general use in place of impalpable powders, the most unpleasant of all forms of medicine. An English chemist has lately introduced the following method of granulating medicines: The powder to be granulated is placed in a mortar, and mucilage of gum acacia is gradually added until a crumbly mass is made; this is then rubbed through a wire sieve (about 12 meshes to the inch), and the granules produced are spread out on paper, and left to dry spontaneously, or they are placed in a copper pan, and kept in a constant motion over a stove until dry; when perfectly dry, they are placed in a mortar, and a sufficient quantity of strong tincture of tolu (3 dr. to 1 oz.) is added to them, until by constant stirring they all appear glossy and shining; they are then dried again by a gentle heat, being kept in constant motion. The granules thus formed keep well, are tasteless, and are much more elegant and agreeable preparations than pills or ordinary powders. Many saline substances are granulated by the simple process of dissolving the salt in water, and evaporating to dryness with constant stirring.

**Metals** are granulated (reduced to drops, grains, or coarse powder) by pouring them, in the melted state, into water. In many cases they are allowed to run through the holes of a species of colander or sieve to produce minute division; and in order to render the drops spherical, they are allowed to fall from a sufficient height to permit of their acquiring the solid state before striking the water. Lead shot is made in this way. Shot towers are often upwards of 100 feet in height.

**Grapes** [Fr. *raisins*; Ger. *Trauben*; It. *grapi*, *grappoli*; Port. *uvas*; Sp. *ubas*], the fruit of the grape-vine, *Vitis vinifera*, a tree with long slender branches, generally found indigenous in countries lying between 28° and 44° N. lat., and between 26° and 75° E. lon., but the growth of which in the open air has been extended by cultivation 10° on each side of that range. This fruit is made an object of attention chiefly in the countries of the

S. of Europe, although in none have *G.* been produced equal to those of Syria, as regards the size of the berries and weight of the branches. *G.* are chiefly used in the manufacture of wine, but they are also extensively consumed as food, and in this country are a common article of the dessert. For the latter purpose they are mostly imported in a dried state (see *RAISINS*) from Spain and Turkey; while a small kind, much used in puddings (*CURRENTS*), are brought from the Ionian Islands and Greece. The only green *G.* imported to any extent into the U. States are the large solid Malaga *G.*, which are in large bunches. They are put up in sawdust and packed in casks. The most valuable *G.* grown in this country are from the Concord, Catawba, Delaware, and Norton's Virginia vines, which are natives of America. These *G.* are of a purple color, and have as luscious a taste as the best *G.* of Europe. See *WINE*.

*Imp. duty*, 20 per cent; juice or pulp, 25 per cent.

**Grape-seed Oil**, a yellow and slightly odorous oil, prepared from the seeds of the common grape by pressure. It has a mild taste when fresh, but becomes thick and rancid by age.

**Grape-Sugar**. Same as *GLUCOSE*.

**Graphite**. See *PLUMBAGO*.

**Grapholite**, a description of writing-slate.

**Graphometer**, a mathematical instrument for measuring angles.

**Graphotype**, a modern process of engraving which produces an effect somewhat similar to that of wood-engraving. It is an American invention, but is more used in England than in this country. It is described as follows: Finely powdered chalk is spread thickly on a metal plate, and then subjected to hydraulic pressure till it becomes a solid mass with a beautiful white surface, slightly shining, but not inconveniently brilliant. On this surface the artist draws in a glutinous ink, perfectly black, flowing from a finely pointed little brush; the pen cannot be used, on account of the friability of the chalk. The ink glues the particles of chalk where it passes, and when the drawing is complete the white spaces between the lines are easily hollowed by rubbing them gently with a piece of velvet or a light brush. The black lines remain in relief, like the lines of a woodcut. The plate is then dipped in a solution of flint, and so hardened, after which a stereotype cast or an electrotype copy is taken from it, and this is used as a stereotype or electrotype.

**Grapple**. See *ANCHOR*.

**Grapple, Grappling-Iron**, a hook or crooked iron instrument used to seize and hold fast another vessel. — A grasping tongs, varying in shape in its various uses. The *G.* represented in Fig. 243 are employed for extracting obstructions from bored wells or shafts.

**Grass-Cloth**. See *CHINA GRASS-CLOTH*.

**Grass Mats**, door-mats made of Spanish or other kinds of grasses.

**Grass-Oil**, a name given to some essential oils obtained from scented grasses in India, as that from the lemon-grass, the grass-oil of Nemaar, etc. It is sometimes called ginger-grass oil.

**Grass-Plot**, a lawn of trimmed grass.

**Grass-Tree**, a name in Australia for some liliaceous plants, species of *Xanthorrhoea*, from which a resin is obtained, known in commerce as gum acroides.

**Grate**, a frame of iron bars used for burning coal as fuel. In the construction of a grate it is desirable to make the perpendicular height of the fuel as great as is consistent with safety. A stra-

tum of burning coal will radiate considerably more heat into an apartment if placed vertically than if arranged horizontally; besides which, a great saving of fuel will be effected in proportion to the heat radiated.

**Grater**, a rubbing or scratching utensil of iron, having a rasping surface, for domestic use, as a nutmeg *G.*, arrow-root *G.*, rasps, etc. — Also, in book-binding, an iron tool for rubbing the backs of sewed books after pasting.

**Graticulation**, the division of a drawing into squares.

**Grating**, an open lattice-work of wood or iron — A cross-barred covering for the hatchways of a ship.

**Gratis**, without charge, fee, or recompense; for nothing.

**Gravecembalo**, a harpsichord.

**Gravel**, a collective name for pebbles, small pieces of rock that have become rounded by attrition. They may be as small as a pea, or as large as an egg, and may comprise different kinds of stone. *G.* is much used in making concrete and artificial stone.

**Graver**, an engraver's burin, or square piece of steel fixed in a handle, and bevelled diagonally at the end. — An instrument used for turning iron, after it has been roughed out by the "heel-tool."

**Graves**. See CLARET WINES.

**Gravières**. See BURGUNDY WINES.

**Gravimeter**, an instrument for measuring the specific gravity of bodies. See HYDROMETER.

**Graving-Dock**. See DOCK.

**Gravity**, the attractive force by which bodies fall towards the centre of the earth. Weight is the measure of gravity.

*Specific Gravity* is the comparative density of various substances: it affords the means of readily determining the bulk from the known weight, or the weight from the known bulk; and this will be found more especially useful in cases where the substance is too large to admit of being weighed, or too irregular in shape to allow of correct measurement. The standard with which all solids and liquids are thus compared is that of distilled water, one cubic foot of which weighs 1000 oz avoirdupois; and the sp. gr. of a solid body is determined by the difference between its weight in the air and in water. Thus, if the body be heavier than water, it will displace a quantity of liquid equal to it in bulk, and will lose as much weight on immersion as that of an equal bulk of the fluid. Let it be weighed first, therefore, in the air, and then in water, and its weight in the air be divided by the difference between the two weights, and the quotient will be its sp. gr., that of water being unity. *Example*. A piece of copper ore weighs 551 oz in the air, and 43 $\frac{7}{8}$  oz in water: required its sp. gr.

$55.25 - 43.75 = 12.5$ , and  $155.25 \div 12.5 = 12.5$ , the sp. gr. If the body be lighter than water, it will float, and displace a quantity of fluid equal to it in weight, the bulk of which will be equal to that only of the part immersed. A heavier substance must therefore be attached to it, so that the two may sink in the fluid. Then the weight of the lighter substance in the air must be added to that of the heavier substance in water, and the weight of both united, and the quotient will be the sp. gr. of the lighter substance required. *Example*. A piece of fir weighs 40 oz in the air, and being immersed in water attached to a piece of iron weighing 31 oz., the two together are found to weigh 3.3 oz. in water, and the iron alone 25.8 oz. in the water: required the sp. gr. of the wood.

$40 + 25.8 = 65.8 - 3.3 = 62.5$ ; and  $40 \div 62.5 = 0.64$ , the sp. gr. of the fir.

Fig. 243. — GRAPPLE.

The sp. gr. of a fluid may be determined by taking a solid body, heavy enough to sink in the fluid, and of known sp. gr., and weighing it both in the air and in the fluid. The difference between the two weights must be multiplied by the sp. gr. of the solid body, and the product divided by the weight of the solid in the air; the quotient will be the sp. gr. of the fluid, that of water being unity. *Example*. Required the sp. gr. of a given mixture of muriatic acid and water; a piece of glass, the sp. gr. of which is 3., weighing 5 $\frac{1}{2}$  oz. when immersed in it, and 6 oz. in the air.

$6 - 3.75 = 2.25 \times 3 = 6.75 \div 6 = 1.125$ , the sp. gr. Since the weight of a cubic foot of distilled water, at the temperature of 60° F., has been ascertained to be 1000 avoirdupois oz., it follows that the sp. gr. of all bodies compared with it may be made to express the weight, in oz., of a cubic foot of each, by multiplying these sp. gr. (compared with that of water as unity) by 1000. Thus, that of water being 1, and that of silver, as compared with being 1047 $\frac{1}{4}$ , the multiplication of each by 1000 will give 1000 oz. for the cubic foot of water, and 1047 $\frac{1}{4}$  oz. for the cubic foot of silver. See HYDROMETER.

**Gravy-Dish**, a large table-dish for a joint, with a well for gravy.

**Gravy-Spoon**, a large spoon used at table for helping gravy to guests.

**Gravy-Strainer**, a small wire or hair sieve, used for culinary purposes.

**Gray**, a color, which is white with a mixture of black; ash-colored. The term is also applied to fabrics of cotton, linen, or worsted, or to mixed fabrics of these materials, in the state in which they come from the loom or spindle, and before they are bleached or colored.

**Gray Goods**, cotton fabrics woven in the gray and known as printing cloths.

**Grazier**, one who rears or feeds stock; a cattle-dealer.

**Grease**, a general name for animal fat of any kind. — Melted tallow, with soda, palm-oil, and water, used as a lubricator for the axles of railroad cars.

*Imp. Duty*. All not specified, 10 per cent; for use as soap-stock only, not otherwise specified, free; known as *brown grease*, obtained by pressure from wool-skins, as animal oils, 20 per cent.

**Grease-Box**, the receptacle over the axle of a railroad car holding grease; also the portable box in which grease is carried to replenish the above.

**Grease-Cock**, a short pipe fixed in the cylinder cover of a steam-engine, with two stopcocks inserted at a short distance apart, and a funnel at the top for holding tallow. When the upper cock is opened, the tallow falls into the intermediate space; the cock is then closed, and the lower one opened for the melted grease to enter the cylinder, and lubricate the piston without allowing the steam to escape.

**Great Britain and Ireland**, a powerful state of Western Europe, which consists of the *Island of Great Britain*, including England, Wales, and Scotland, and the *British Islands*, including Ireland, the Scilly Islands, the Channel Islands, Man, Bute,

Arran, the Hebrides, Orkney, and Shetland Islands. In the above limits it is styled *The United Kingdom of Great Britain and Ireland*, and for the sake of shortness *Great Britain*; while with its colonies and dependencies it constitutes the *British Empire*. The immense area and population of the British Empire were, in 1878, distributed as follows:—

Countries.	Area in Sq. miles.	Population.
United Kingdom .....	121,608	34,160,000
India and Ceylon .....	933,673	138,725,180
Colonies and Dominions .....	7,208,322	11,587,360
Total British Empire .....	8,263,603	249,472,540
Tributary States in India .....	558,724	48,236,200
Total Empire and tributary States.	8,822,327	297,708,740

The government of the British Empire is a constitutional hereditary monarchy. The supreme legislative power of the British Empire is by its constitution given to Parliament. "The power and jurisdiction of Parliament," says Sir Edward Coke, "is so transcendent and absolute that it cannot be confined, either for causes or persons, within any bounds." And, repeating the words, Sir William Blackstone adds, that it is "the place where that absolute despotic power, which must in all governments reside somewhere, is entrusted by the constitution of these kingdoms." The sovereign is not only the head, but also the beginning and the end—*caput, principium, et finis*—of Parliament; he alone can summon Parliament; and no Parliament, save on the demise of a sovereign, can assemble of its own accord. Parliament is summoned by the writ of the sovereign issued out of Chancery, by advice of the privy council, at least thirty-five days previous to its assembling. Act 16 Chas. II., provides that Parliament shall not in future be intermitted for above 3 years at the most, but as the supplies are only granted for a year, the Crown, since the Revolution, is compelled to summon a Parliament annually. By ancient right and usage, lying at the foundation of the constitution, the House of Commons has the exclusive control over taxation, and at its will may grant or refuse supplies to the Crown. It has become customary of late for Parliaments to meet in annual session extending over the first six months of the year. Every session must end with a prorogation, and by it all bills which have not been passed fall to the ground. The prorogation takes place either by the sovereign in person, or by commission from the Crown, or by proclamation. Both houses of legislature must be prorogued at the same time. The present form of Parliament, as divided into two houses of legislature, the Lords and the Commons, dates from the time of Edward II. The *Upper House* consists of peers who hold their seats: 1. By virtue of hereditary right; 2. By creation of the sovereign; 3. By virtue of office,—English bishops; 4. By election for life,—Irish peers; 5. By election for duration of Parliament,—Scottish peers. The Crown is unrestricted in its power of creating peers, and the privilege has been largely used by modern governments to fill the House of Lords, which, in the session of 1878, consisted of 538 members. The *Lower House* of legislature, representing, in constitutional theory, all the "Commons of England," has consisted, since 49 Hen. III., of knights of the shire, or representatives of coun-

ties; of citizens, or representatives of cities; and of burgesses, or representatives of boroughs; all of whom indistinctly vote together. In 1878 there were in the United Kingdom 2,952,005 voters, and in the session of that year the House of Commons numbered 650 members. The powers of Parliament are politically omnipotent within the United Kingdom and its colonies and dependencies. It can make new laws, and enlarge, alter, or repeal those existing. The parliamentary authority extends to all ecclesiastical, temporal, civil, or military matters, as well as to altering or changing the constitution of the realm. Parliament is the highest Court of Law, over which no other has jurisdiction. The *executive government* is vested nominally in the Crown; but practically in a committee of ministers, commonly called the *Cabinet*, which has come to absorb the function of the ancient Privy Council, or "the King in Council," the members of which, bearing the title of Right Honorable, are sworn "to advise the king according to the best of their cunning and discretion," and "to help and strengthen the execution of what shall be resolved." Though not the offspring of any formal election, the Cabinet is virtually appointed by Parliament, and more especially by the House of Commons, its existence being dependent on the possession of a majority in the latter assembly. The member of the Cabinet who fills the position of First Lord of the Treasury is the chief of the ministry, and therefore of the Cabinet. It is at his recommendation that his colleagues are appointed; and he dispenses, with hardly an exception, the patronage of the Crown. Every Cabinet includes the following nine members of the administration: the First Lord of the Treasury, the Lord Chancellor, the Lord President of the Council, the Chancellor of the Exchequer, and the five Secretaries of State. A number of other ministerial functionaries, varying from two to eight, have usually seats in the Cabinet, those most frequently admitted being the Lord Privy Seal, the First Lord of the Admiralty, the President of the Board of Trade, the Vice-President of the Committee of Council on Education, the Postmaster-General, the Chief Secretary for Ireland, and the President of the Local Government Board. The selection usually falls upon those amongst the last-mentioned functionaries whose rank, talents, reputation, and political weight render them the most useful auxiliaries, or whose services, while in opposition, may have created the strongest claims to become members of the Cabinet. It has occasionally happened that a statesman possessing high character and influence accepted a seat in the Cabinet without undertaking the labors and responsibilities of any particular office. Although the Cabinet has been regarded during several generations as an essential part of the institutions of Great Britain, yet it continues to be unknown to the law. The names of the members who compose it are never officially announced; no record is kept of its resolutions or meetings, nor has its existence been recognized by Act of Parliament.—The political divisions of England, Scotland, and Ireland are given below in their respective chapters. London, the capital of the United Kingdom, and the largest city in the world, had in 1878 a population of 3,533,484. London is at the present day what New York will become in the next century—the emporium of the commerce of the world. To attempt a description of its multifarious branches of industry and commerce would require more space than we have at our command, and would, besides, necessitate repetition, almost every im-

portant article on commerce in this work referring to the commerce of London or England. In the following pages, after short notices on the physical geography of England, Scotland, and Ireland, are given the commercial and financial statistics of Great Britain which have found no room in other parts of the work, and a synopsis of her principal seaports.

#### I. ENGLAND.

England, comprising with Wales the southern portion of the island of Great Britain, extends from lat.  $49^{\circ} 48'$  to  $55^{\circ} 45'$  N., and from lon.  $1^{\circ} 45'$  E. to  $5^{\circ} 44'$  W.; area 58,320 sq. m. In shape it is nearly triangular; and, owing to its being surrounded by

ing the indentation being estimated at over 2,000 m. There are few countries more diversified in physical structure, or in soil, climate, and natural scenery, than England. As regards physical structure, it has been truly described to be in itself an "epitome of the geology of almost the whole of Europe." Nearly all the formations of the earth's crust, from the Silurian upwards to the most recent, are to be found, in layers more or less thick, in different parts of England. The mountains of England lie in the N. and W., falling into undulating ground in the centre and towards the S., and leaving the eastern districts, bordered by the German Ocean, a uniform plain. They may be looked upon as one principal chain, often interrupted, however, and with endless ramifications, stretching from the Scottish border, in Northumberland, down to the W. end of Cornwall, jutting out there into the Atlantic. The chain, traced in this direction, commences with the Cheviot Hills, the highest summit of which is Cheviot Peak, in Northumberland, 2,676 feet above sea.

Stretching S. W., the chain next merges into the mountain ranges of Cumberland and Westmoreland, comprising Skiddaw, 3,022 feet, Helvellyn, 3,118 feet, and Scafell, 3,208 feet, above sea. Within these ranges lie the only notable lakes of England, the largest of which, however, Windermere, does not cover more than 3 sq. m. After sending out numerous branches eastwards into the county of York, the chain sinks to modest elevations in Lancashire and Cheshire, but rises again in Wales, where it attains its greatest height in the summit of Wyddva, the pinnacle of the Snowdon range, 3,571 feet above sea. Partly lost in the Bristol Channel, and partly ramifying through Gloucestershire, Wilts, and Somerset, the chain next rises into high table-land in Devonshire, — Dartmoor Forest, averaging an elevation of 1,500 feet above sea, forming its most elevated portion. The chain gradually declines from Dartmoor to the Land's End, and becomes also more contracted in that direction. From the Dunkerry Beacon, on Exmoor, 1,668 feet above sea, the mountain range goes sinking on to Carnwarth, in Cornwall, 849 feet; to Cara Brea, 697 feet; and, finally, to the famous headland of Bolerium, the granite masses of which oppose the ever-surgings waters of the Atlantic, but rise only about 60 feet above them. — *Rivers.* As the mountainous regions are in the W., the principal rivers flow away from them, towards the E., with but few exceptions. Surrounded by the sea, and with a moist atmosphere, England has a comparatively large number of rivers, though none of them of great length, their course being in most instances the shortest allowed by the configuration of the island. At the head of English rivers, with acknowledged supremacy over the rest, stands the *Thames*. It drains an area of 6,160 sq. m., exclusive of its lower estuary, calculated to embrace an additional drainage of about 4,000 sq. m. Next, in extent of area of drainage, come the *Trent* and *Ouse*, the joint waters of which form the *Humber*, carrying off the rainfall from 9,550 sq. m. of land, or about one sixth of the whole of England. The *Witham*, the *Willand*, the *Nen*, and their tributaries, flowing into the old estuary of the Wash, drain together an

Fig. 244. — WESTMINSTER ABBEY.

area of 5,850 sq. m. In comparison with the drainage area of these rivers, running principally from E. to W., that of currents following an opposite direction is small; but several of them are nevertheless of great commercial and industrial importance. Foremost among these westerly flowing rivers stands the *Severn*, the source of which is only a short distance from that of the *Thames*, the watershed being

the sea on all sides, except for a distance of about 70 m. on the Scottish border, it has a most extensive coast-line. The seas which encircle it are the German Ocean, or North Sea, on the E., and the Atlantic Ocean on the W. and S., the latter receiving in some of its parts the names of the Irish or St. George's Channel, and of the English Channel. The coast is much indented, more particularly on the Atlantic side, the total length follow-

formed here by the narrow oölitic escarpment of the Cotswold hills. The Severn drains an area of 8,580 sq. m., being more than that of all the other westward-running rivers together. Next to it stand the *Mersey*, which, with its sea-estuary, drains 1,750 sq. m., the *Acon*, which drains 1,210 sq. m., and the *Eten*, which drains 995 sq. m. of land. In Camden's *Britannia*, published in 1695, there is a list enumerating 553 rivers and streams, with separate names, in England and Wales; but it cannot be said that there are, at the utmost, more than fifty rivers that can properly be described as navigable. The former importance of the rivers of England, connected with each other by a vast network of canals, for inland navigation, has suffered much since the introduction of railways; still they continue of great benefit for cheap, if slow, communication. Of the highest commercial value still are the Thames, the Humber, the Mersey, and the Severn, but these four principal English rivers derive their importance mainly, if not entirely, from being arms of the sea. — *Climate*. Affected by its insular position, with no part of its land more than 100 m. from the sea, and perhaps equally as much — though modern scientific investigation has not quite set this matter at rest — by that most remarkable current of the ocean known as the Gulf Stream, the climate of England is much milder than that of any other country in the same latitude on the continent of Europe or in America. The mean annual temperature of England in recent years has been 49.7° — that of summer averaging 60.8°, and that of winter 39.5°. The principal cause of this very high as well as very equable temperature, contrasting to a marvellous extent with that of other countries in like latitude, such as, for example, Northern Canada, is generally ascribed, with but few dissenting opinions, to the constant flow of heated water bathing the W. shore of the island. The vast current of the Gulf Stream, originating within the land-locked area of the Gulf of Mexico, where the tropical sun is heating the waters as in an immense caldron, after running for some distance E. into the open ocean, then turns direct to the N. E., so that the first land it meets with, and which feels its effect, is the shores of Ireland and England. The actual amount of heat so given to England must be enormous, since the temperature of the Gulf Stream is at least 8° above that of the surrounding waters of the North Atlantic. A recent scientific traveller, making experiments in a voyage from England to the U. States, found that, while in the Gulf Stream the water was at sunrise always not less than 4° above the temperature of the air, by a sudden change, on quitting the N. E. current, the temperature of the waves was found to be, on the average, 4° below that of the air. England is thus in the position of a great hot-house, kept above the surrounding temperature by never-ending currents of warm air. But it is not warmth alone, but moisture, which the Gulf Stream gives to England. Here, as in the greater part of W. Europe, the prevailing winds are from the S. W., bringing with them the warm, moist air of the great Atlantic current, and discharging it in rainfall all over the land. This is strikingly shown in the statistics of rainfall in England, which prove it far higher in the W. than in the E. counties, and greatest in those parts where the moist Atlantic air-currents are unimpeded by mountain ranges. In the extreme S. W., in Cornwall, from 22 to 47 inches of rain fall every year, and the average may be taken at 33 inches; while in the adjoining county, Devonshire, a little further inland, the average is but 32 inches. However, the high range of the Dartmoor hills causes a much greater variation in the amount of rainfall in the latter county than in the former; for while no less than 52.33 inches fall on the summit of Dartmoor, only 19.87 inches fall at Sidmouth, lying sheltered to the W. The same is the case farther E. in Somersetshire, where 33.76 inches of rain fall annually at West Harpree, facing the Bristol Channel, while only 19 inches fall at Taunton, shut off from the moist gulf current by the Ex-moor range. So it is everywhere all over England, with the general result that in the W., and more especially the S. parts of it, there is more rainfall than in the E., the variations also being much less in the latter districts. In the metropolitan counties of Middlesex, Kent, and Surrey the variations are no greater than from 16.22 inches at Hamptonstead to 28.90 inches at Cranbrook. The highest rainfall anywhere yet ascertained in England and Wales was at Beidgelert, Carnarvonshire, where it reached the enormous amount of 101.53 inches in the year 1870. Lying on the W. slope of the highest summit of the Snowdon range, close to the Atlantic, the little village received a surcharge of the moist air of the Gulf Stream. — *Soil*. Co-operating in their influence, climate and geological formation have given England a soil moderately fertile, yet adapted on the whole more for pasture than for agriculture. In Wales, and other parts of N. and W. England through which stretch the principal mountain ranges, the Silurian rocks, covered on their upper surface chiefly with hard gritty and slaty material, difficult to decompose by atmospheric action, form but little soil, so that the ground must to a large extent remain untillied, leaving it at the same time well adapted for pastoral purposes. Again, through the inland counties, from Northumberland to Derbyshire, there runs another long tract of hilly country, composed of carboniferous rocks, so constituted as to be unfit for ordinary agriculture, except where intersected by stream-fed valleys. Further E. come the bleak moorlands of Yorkshire, which, barren in their nature, are being surrounded and intersected by some of the most fertile tracts in

England, extremely well cultivated and thickly inhabited. On the whole, it may be said that while much of the high-lying ground is fit only for pastoral purposes, the low lands are more or less fertile, the extreme moisture of the air having caused the complete disintegration even of such old geological formations as those of the Red Sandstone. It is a somewhat singular fact that nearly all the districts of England, where fruit-trees are grown in large quantities, lie chiefly upon red rocks, sometimes of the Old and sometimes of the New Sandstone strata. There cannot be a doubt, however, that, on the whole, the soil of England would be very barren, repaying poorly the labors of the husbandman, but for the vast cover of warmth and moisture received from the waters of the Atlantic, which favors it as the sun of more S. regions, and makes its fauna and flora equal to those of any country in the temperate zone. — *Civil divisions and population*. The physical aspect of England has had little to do with its civil divisions, which are somewhat arbitrary, and remote in their origin. The division of the country into tithings, hundreds, and counties is generally attributed to King Alfred, but it is more probable that he only systematized what already existed, in the general survey which was taken during his reign. English county names occur in history before the extinction of the Heptarchy, some of the smaller kingdoms of which, as Kent, Sussex, and Essex, became counties under the new political settlement. At the same time the Kingdom of Wessex was composed of counties with still existing names, — Berkshire, Hampshire, Wiltshire, and Somersetshire. The following table shows the area, inhabited houses, and population of the counties into which England and Wales are usually divided: —

Counties or Shires.	Area in Statute Acres.	Inhabited Houses, 1871.	Population.

Total of England and Wales....	37,324,833	4,259,117	20,066,224	22,712,266

England and Wales, taken by themselves, are more densely populated than any other country in Europe, except Belgium. On an area of 58,320 sq. m. or 37,324,883 acres, there lived in 1871, according to the census, 22,712,266 inhabitants, or 389 individuals per sq. m. The population was as follows at the 8 enumerations, 1801 to 1871:—

Date of Enumeration.	Population.		
	Males.	Females.	Total.
1801, March 10th.....	4,254,735	4,637,801	8,892,536
1811, May 27th.....	4,873,695	5,290,651	10,164,256
1821, May 28th.....	5,850,319	6,143,917	12,000,236

1841, June 7th.....	7,777,586	8,135,562	15,914,148
1851, March 31st.....	8,781,225	9,146,384	17,927,609
1861, April 8th.....	9,776,259	10,289,365	20,065,224
1871, April 3d.....	11,058,934	11,653,332	22,712,266

At the beginning of 1878 the 13 largest towns in England and Wales, each with over 100,000 inhabitants, were as follows, according to the estimates of the registrar-general, based upon the returns of births and deaths: London, 3,533,484 inhabitants; Liverpool, 527,083; Manchester, with Salford, 500,337; Birmingham, 377,439; Leeds, 291,580; Sheffield, 274,914; Bristol, 199,539; Bradford, 173,723; Newcastle-on-Tyne, 139,929; Hull, 133,933; Portsmouth, 124,867; Leicester, 113,581; and Sunderland, 103,343 inhabitants. One fourth of the total urban population of England and Wales live in London, and not far from one third live in 18 large cities and towns, selected by the registrar-general for the publication of weekly rates of mortality. The following is a list of these 13 towns, all of them containing over 60,000 inhabitants, with their population at the censuses of 1861 and 1871, and the rate of increase per cent during the decennial period.

Cities and Towns.	1861, April 8.	1871, April 3.	Rate of Increase per cent.
London.....	2,803,989	3,254,260	16.1
Liverpool.....	443,933	493,405	11.1
Manchester.....	338,722	351,189	3.7
Salford.....	102,449	124,801	21.8
Birmingham.....	296,076	343,787	16.1
Leeds.....	207,165	259,212	25.1
Sheffield.....	185,172	239,946	29.6
Bristol.....	154,093	182,552	18.5
Bradford.....	106,218	145,830	37.3
Newcastle-on-Tyne.....	109,108	128,443	17.7
Hull.....	97,661	121,892	24.8

Sunderland.....	78,211	98,242	25.6
Leicester.....	68,056	95,220	40.0
Nottingham.....	74,693	86,621	16.0
Oldham.....	72,333	82,629	14.2
Norwich.....	74,891	80,396	7.3
Wolverhampton.....	60,860	68,291	12.2
Total.....	5,368,434	6,270,275	16.8

In 1878 the number of paupers, *exclusive of vagrants and casual poor*, in receipt of relief in the several unions and parishes, constituted under boards of guardians in England and Wales, amounted to 742,703. During the same year the number of criminal offenders committed for trial was as follows: men, 12,536; women, 3,354; total, 15,890. Convicted, 11,942.

Subjoined is the birth, death, and marriage rate of the population of England and Wales for the 15 years from 1863 to 1877, with the estimated population for the middle of each year:—

Years.	Estimated Population.	Births.	Deaths.	Marriages.
1863	20,590,356	729,399	473,837	173,510
1864	20,834,493	740,275	495,531	180,387
1865	21,085,130	747,879	490,909	185,474
1866	21,342,864	753,870	500,689	187,776
1867	21,608,236	768,949	471,073	179,154
1868	21,882,059	786,153	480,622	176,962
1869	22,164,847	772,877	495,086	175,629
1870	22,457,399	792,129	515,544	181,655
1871	22,750,359	797,428	514,879	190,112
1872	23,067,385	825,907	492,665	201,287
1873	23,350,414	829,778	492,520	205,615
1874	23,648,609	854,956	526,632	202,010
1875	23,944,459	850,137	546,317	201,212
1876	24,244,010	887,993	610,315	201,874
1877	24,547,309	887,055	500,348	194,343

The proportion of male to female children born in England is as 104,811 to 100,000; but emigration, war, and perilous male occupations modify this proportion in 10 years to the extent that there are 100,000 women, of all ages, to 94,000 men in England.

*Agriculture.* The returns published by the government in the New Domesday Book show that in the year 1873 there were in England and Wales 972,835 owners of land, holding together 23,013,515 acres, of a gross estimated rental of £99,382,301. The subjoined table exhibits the number of land-owners, under thirteen classifications of ownership, the total extent of lands held by each class, and the gross estimated rental:—

Classification of Ownership.	Number.	Extent of Lands in Acres.	Gross Estimated Rental.
Less than one acre.....	703,289	151,172	29,127,679

Rentals not specified.....	113	1,424	.....
Total of England and Wales (exclusive of the Metropo- lis).....	972,835	33,013,515	99,352,301

Of the total area of England and Wales, comprising 37,324,883 statute acres, no less than 4,311,398 are not accounted for in the foregoing returns. These must consist partly of waste spaces, moorlands, and other areas, including that of the metropolis and crown property, intentionally set aside; and partly of lakes, rivers, and roads. This leaves perhaps a million or more of acres wanting, through great errors and omissions in the parish lists on which the returns were based. Still, with all these imperfections, and the undoubted miscalculations in the rental values, generally admitted to be large under-statements, enough remains to give a fair idea of the division of landed property in England and Wales. One of the most notable features of the returns is the fact that the number of land-owners possessed of less than one acre is as high as 703,289, being 73.3 per cent of the whole. The great decrease seen in the number of those who possess from one acre to ten being considerably under one fifth of the first class, is remarkable; and no less so is it that there are more land-owners who possess from 100 to 500 acres than who possess from 50 to 100 acres. The total number of land-owners in England and Wales is altogether, according to these returns, very far above what was formerly believed, for in the census returns of 1861 the number of "landed proprietors" was given at 30,766, and in those of 1871 at 22,964. But while it is seen that real property is so widely distributed, there appears not the less, from the Blue-Book of 1878, the all-important fact that the proprietors of over 5,000 acres, who deserve, more especially, the title of "great" land-owners, 874 in number, hold 9,367,031 acres, or more than one fourth of the country. The owners of 1,000 acres and upwards, numbering 5,408, hold 18,695,528 acres, being more than one half of the country; and those of 500 acres and upwards, 10,207 in number, hold 22,013,206 acres, or two thirds of the whole of England and Wales. These 10,207 owners well deserve the old title of the "upper ten thousand." The following proprietors outside the metropolis are returned in 1873 as either holding upwards of 50,000 acres, or having estimated rentals exceeding £100,000 per annum:—

Proprietor.	County.	Acres.	Rental.
Duke of Northumber- land.....	Northumberland..	181,616	161,874
Duke of Devonshire..	Derby, York (W. R.), Lancaster, Sussex..	126,901	127,633
Sir W. W. Wynn, Bart.	Denbigh, Montgom- ery, Merioneth.....	87,256	42,882
Duke of Cleveland.....	Durham, Salop.....	81,441	61,824
Earl of Carlisle.....	Cumberland, York- shire, Northumber- (N. R.).....	78,540	49,001
Duke of Bedford.....	Bedford, Cambridge, Devon.....	74,996	127,653
Earl of Lonsdale.....	Westmoreland, Cum- berland.....	67,457	69,959

Proprietor.	County.	Acres.	Rental, in £.
Earl of Powis .....	Montgomery, Salop...	60,531	62,694
Duke of Rutland .....	Leicester, Derby.....	57,982	70,998
Earl of Derby.....	Lancaster, Derby.....	56,471	163,195
Earl of Yarborough.....	Lincoln .....	55,272	76,226
Lord Leonfield.....	Sussex, York (E.R.), } Cumberland .....	54,615	51,940
Marquis of Ailesbury.....	Wilt, York (N. R.)... }	53,362	58,030
Earl Cawdor .....	Carmarthen, Penm- } broke.....	51,517	34,987
Sir Lawrence Palk, Bart.	Devon .....	10,109	109,275
Sir J. W. Ramsden, Bart	York (W. R.).....	8,589	167,601

In some cases the estimated rental exceeds the income derived from the property. Together with the returns of land-owners in England, there were issued similar ones for Scotland and Ireland. It is not a little interesting to compare the relative facts given in these various returns, which illustrate to a striking degree the diversity of the ownership of the soil and division of the land in the three portions of the United Kingdom. While in England the proportion of land-owners below an acre is 73.3, it is 85.5 per cent in Scotland, and 52.6 in Ireland. Again, of land owners possessing more than one acre, the proportion who have less than 500 acres is 96.1 per cent in England, 85.5 per cent in Scotland, and 80.1 per cent in Ireland. With regard to England, the twelve largest owners hold in the aggregate 1,058,583 acres, while the twelve largest owners in Scotland possess 4,339,722 acres, and the twelve largest owners in Ireland 1,297,888 acres. Thus the ownership of the twelve principal land-owners of England is not one fourth that of the twelve chief land-owners of Scotland. The total number of land-owners in each of the divisions of the United Kingdom was given as follows in the official returns:—

Divisions.	Number of Owners of less than one acre.	Number of Owners of one acre and upwards.	Total Number of Owners.
England.....	703,289	269,547	972,836
Scotland.....	113,005	19,126	132,131
Ireland.....	35,144	32,572	68,716
United Kingdom ..	852,438	321,245	1,173,683

The gross estimated rental value of the landed property enumerated in the returns was stated as follows:—

*Estimated Rental Value of Land.*

England .....	£99,352,301
Scotland .....	18,698,774
Ireland .....	13,417,758
United Kingdom .....	£131,468,833

In England, one person in 20 of the population is an owner of land, against one in 25 in Scotland, and one in 79 in Ireland. The proportion of owners of land to inhabited houses is 1 to 4 in England, 1 to 3 in Scotland, and 1 to 14 in Ireland. In England, the average extent of land held by each owner is 33 acres, 3 rods, 30 perches, while it is 143 acres, 1 rood, 6 perches in Scotland, and 293 acres, 1 rood, 32 perches in Ireland. The average estimated rental of each owner of land in England is £102 3s. (\$510.75), against £141 8s. (\$707) in Scotland, and £195 3s. (\$975.75) in Ireland. The average estimated rental value of the whole of the land in England and Wales is given at £3 0s. 2d. (\$15.04) per acre, which is thrice that of Scotland, where the average is 13s. 9d. (\$4.95) per acre, and four and a half times as much as in Ireland, where it is 13s. 4d. (\$3.33) per acre.

The following table furnishes a concise account of the acreage under crops and otherwise, together with the number of live-stock in the two divisions of grazing and corn-growing counties of England, according to the agricultural returns for the year 1877:—

	Grazing Counties.		Corn Counties.

Pigs.....	1,028,734	48.6	1,086,017	51.4

It appears from the last Agricultural Returns that the extent of arable land in England and Wales is on the decrease, as is also the produce of live-stock, while, on the other hand, the area of pasture-land is on the increase. The land under wheat fell from 3,336,888 acres in 1872 to 2,987,129 in 1877, in England; and from 126,397 acres in 1872 to 100,226 in 1877, in Wales. During the same period the acreage under potatoes fell in England from 339,056 to 303,964, and in Wales from 48,417 to 42,942; and that under clover in England from 2,822,302 to 2,737,387, and in Wales from 370,850 to 351,797. In the acreage under barley and oats there was a slight increase in England, but a decrease in Wales; while in the acreage under turnips and swedes there was a trifling increase in England and a decrease in Wales during the period. Taken altogether, the extent of arable land in England fell from 13,839,000 acres in 1872 to 13,454,000 acres in 1877, being a decrease of 385,000 acres. In Wales, the extent of arable land sank from 1,104,000 acres to 999,000 acres in the same period, the decrease amounting to 105,000 acres. The decrease of arable land during the five years was very steady, and so likewise was the increase in the acreage of pasture-land. There were in England under pasture—exclusive of heath and mountain land—9,991,000 acres in 1872, and 10,858,000 acres in 1877, the increase in the five years amounting to 867,000 acres, being more than double the extent of decrease of arable land. In Wales there were under pasture 1,532,000 acres in 1872, and 1,732,000 acres in 1877, making the increase amount to 200,000 acres, this also being not far from double that of the decrease in arable land. The decrease in the extent of arable land, and simultaneous increase of pastures, is more or less satisfactorily explained by the fact of England being supplied with corn from the U. States and other foreign countries, where it can be grown cheaper than at home; while the produce of pasture-lands cannot be brought in the same way into the country. But if the decrease of arable land and increase of pastures can be thus explained, it is not so easy to account for the decline of live-stock which also took place during the same period, more especially from 1874. It might have been expected that the widening of the pastoral area would have led to an increase of live-stock, but the contrary was the case, more especially as regards horned cattle and sheep. In England there were 4,205,440 head of cattle in June, 1874, and 3,979,650 head in June, 1877, so that there was a decrease of 325,790 head in three years. During the same period the number of cattle in Wales fell from 695,105 to 616,209, being a decline of 48,896. The decrease in numbers was even greater in sheep. There were 19,859,758 sheep in England in June, 1874, and 18,330,377 in June, 1877, being a decrease of 1,529,381. In Wales, during the same period, the number of sheep fell from 3,034,696 to 2,862,013, being a decrease of 202,683. Thus the total decline in the number of sheep in England and Wales was no less than 1,732,064 in the short space of three years. The great diminution of live-stock during the triennial period from 1874 to 1877 was not confined to England and Wales, but occurred simultaneously in Scotland, as well as in Ireland, being greatest in the latter country, where the decline in sheep alone amounted to 101 per

cent. We see, besides, that in the census returns of 1871 the number of persons entered as "agriculturists" in England and Wales was 1,447,481, comprising 1,254,031 men, and 183,450 women. At the preceding census (1861) the number of "agriculturists" was given at 1,833,552, showing a diminution of 386,171 within the decennial period. We think that the high rental of the land, combined with the limited ownership of the soil, two thirds being in the hands of little over ten thousand persons and the rest divided among nearly a million, have much to do with the rapid decline of agriculture in England.

## II. SCOTLAND.

Scotland, the northern portion of Great Britain, extends in its main land from lat.  $54^{\circ} 38'$  to  $58^{\circ} 41'$  N., and lon.  $1^{\circ} 45'$  to  $6^{\circ} 14'$  W., and including the islands to lat.  $60^{\circ} 50'$  N. and lon.  $8^{\circ} 35'$  W. It is separated from England by a waving line of the Cheviot Hills in the centre; by the Tweed, which enters the sea of Berwick, on the E.; and by the Solway Frith on the W. Its E. shores are washed by the North Sea, and its W. by the Atlantic. It is of an oblong, irregular form, extending longitudinally due N. and S. 290 m., and varying in breadth from 175 to 100, 50, and 30 m. Area 30,885 sq. m., including its islands, 186 in number. Few countries of equivalent magnitude display so great an extent of seacoast as Scotland, its aggregate length being about 2,506 m. It is extremely irregular in its surface and outline, and, compared with England, may be said to be sterile, rugged, and mountainous. With the exception of a few rich alluvial tracts, there are no extensive vales in S.; its surface, even when least mountainous, being generally varied with hill and dale. It has been separated into the two great divisions of the *Highlands* and the *Lowlands*, and also into the Northern, the Middle, and the Southern. The first, or Northern, division is cut off from the Middle by the chain of lakes which stretch from the Moray Frith to Loch Linnhe. The second, or Middle, division is separated from the Southern by the friths of Forth and Clyde, and the Great Canal. The Northern division consists generally of an assemblage of vast mountains, here and there intersected by fertile valleys, chiefly towards the S. and E. coasts. A portion of them are clothed with green herbage, more especially where sheep-farming prevails; but, in general, they are covered with heath growing upon peat, rock, or gravel; and they frequently terminate in mountain-caps of solid rock, or in vast heaps or cairns of bare and weather-beaten stones. The Middle division is also mountainous, the Grampian range intersecting this district, and extending from the eastern to the western sea, and occupying a breadth of from 40 to 60 miles. The western parts of Argyllshire, which are also included in this district, are rugged, mountainous, and deeply indented by inlets of the ocean. In these two divisions, which comprehend more than two thirds of Scotland, the arable ground consists of but a small proportion to the mountainous regions. On the eastern coasts, however, the proportion of the cultivated to the uncultivated land is much greater. In the Southern division every variety of aspect is found; verdant plains, watered by copious streams, and covered with innumerable cattle; gently rising hills and bending vales, fertile in corn, waving with wood, and interspersed with meadows; lofty mountains, craggy rocks, deep narrow dells, and tumbling torrents; nor are there wanting as a contrast, barren moors and wild uncultivated heaths. In this district are the different ranges of the Cheviot Hills; the Sidlaw Hills, terminating at Perth; the Ochil Hills, forming the middle division; and the hills of Kilsyth and Campsie. Between the Sidlaw ridge and the Grampian Mountains lies the extensive and fruitful valley of *Strathmore* stretching from Stirling to Stonehaven. Another strath or valley, called *Glenmore*, runs across the country from Loch Eil to the Murray Frith. This strath, in different parts, has particular names.—*Rivers*. In the Northern division, the principal are the Beaulie, Naver, Thurso, etc.; in the Middle division, the Spey, the Dee, the Don, and the North and South Esk; about 30 m. farther S. is the Tay, one of the largest rivers in Britain. In the Southern district are the Forth, the Clyde, and the Tweed, and the numerous rivers which empty themselves into the Irish Sea and the Solway Frith; the Ayr, the Girvan, the Southern Dee, the Nith, the Annan, and the Liddell.—*Lakes, or Lochs*, are numerous and extensive. The principal are Lochs Lomond, Awe, Ness, Shin, Marce, Tay, Erich, Shiel, Lochy, and Katrine.—*Islands*. The principal groups are the Orkneys, the Shetlands, and the Hebrides, besides Arran and Bute.—The climate is extremely variable. From its insular situation, however, the cold in winter is not so intense, nor the heat in summer so great, as in similar latitudes on the Continent; and although the range of the thermometer is considerable, it seldom maintains an extreme for any length of time. The annual average temperature may be estimated at from  $45^{\circ}$  to  $47^{\circ}$ . The mildness of the winter is well illustrated by the fact that Mr. McNab, of the Royal Botanical Gardens at Edinburgh, reported 133 species of flowers in bloom on New Year's Day, 1874, of which 35 were winter or spring flowers, and 103 summer or autumn flowers.—*Minerals*. Iron-stone, iron-ore, lead, and septaria iron-stone are abundant. Copper has been discovered in many places. The other metallic substances are cobalt, bis-

moth, manganese, wolfram, plumbago, and mercury: the latter in very small quantities. Coal is abundant in the Southern and Middle districts. Limestone, freestone, or sandstone, and slate, are found in every district. Marbles are also found. Most of the gems and precious stones have been found among the mountains of Scotland, the diamond excepted. Jasper is found in great variety, and rock-crystal, commonly denominated *carraigorm*, from the mountain of that name in Banffshire. Chalcedony is also found. Scotland is divided into 33 civil counties, grouped under 8 geographical divisions, as follows:—

Divisions and Civil Counties.	Inhabited Houses.	Population.		
		Males.	Females.	Total.
1. Northern : —				
Shetland .....	5,740	13,080	18,525	31,605
Orkney .....	6,391	14,346	16,926	31,172
Caithness .....	7,476	18,329	21,050	39,379
Sutherland .....	4,798	11,127	12,559	23,686
2. Northwestern : —				
Ross and Cromarty ..	15,932	38,029	42,880	80,909
Inverness .....	16,659	40,798	46,982	87,480
3. Northeastern : —				
Nairn .....	2,046	4,771	5,442	10,213
Elgin .....	8,594	20,278	23,320	43,598

Total population ...	412,185	1,603,143	1,756,875	3,360,018
Population to the 1 square mile ...				169

The following table exhibits the number of the population of Scotland at the dates of the several enumerations, together with the increase between each census, and the percentage of increase:—

Dates of Enumeration.	Population.	Increase.	Percentage of decennial Increase.
March 10, 1801 .....	1,608,420	.....	.....
May 17, 1811 .....	1,805,844	197,424	12.27
May 28, 1821 .....	2,001,521	285,657	15.82
May 29, 1831 .....	2,264,386	272,865	13.04
June 7, 1841 .....	2,620,184	255,798	10.82
March 31, 1851 .....	2,888,742	268,558	10.25
April 8, 1861 .....	3,063,204	173,552	6.00
April 3, 1871 .....	3,360,018	296,724	9.80
Increase in 70 years .....		1,751,598	100.12

*Edinburgh*, the ancient capital of Scotland, is situated in the county of Mid-Lothian or Edinburgh, to the S. of the Firth of Forth. The Royal Observatory, which is built on the summit of the Calton Hill, in the N. E. quarter of the city, is in lat.  $55^{\circ} 57' 23''$  N., lon. 12 m. 43.06 s. of time W. of the meridian of Greenwich. Edinburgh stands on high, uneven ground, being built on three ridges running E. and W. The central ridge on which the city was originally built, terminates abruptly, on the W., in a precipitous rock nearly 400 feet above the level of the sea, on which is the castle, while to the E. it inclines to a plain or valley. From an early date down to this century the special associations with the national literature have been identified with the ancient capital, and have won for it the name of Modern Athens. To this the actual correspondence of its site to that of Athens no doubt also contributed. Literary taste and culture still characterize Edinburgh society; but, apart from the exceptional influences of pre-eminent genius, the causes which largely contributed to give it so special a character no longer exist. In Scott's early days a journey to London was beset with difficulties, and even dangers; whereas railroads have now brought it within a few hours' distance, and Scottish artists and literary men are tempted to forsake Edinburgh for the great centre of all national activities. Nevertheless, the influence of the past survives in many ways. Edinburgh is not a manufacturing city, but retains even now something of the character of the Scottish capital, as the resort of those whose means enable them to enjoy in ease and comfort its social amenities without indulging in the costly gayeties which a London season involves. The progress of Edinburgh during the present century has been remarkable. In 1801 the population, including the Canon-gate and other inter-mural suburbs was 63,341; in 1877 it had risen to 213,729. The Registrar-General of Scotland reported

other waste lands. Out of the total, computed at 19,496,132 acres, only 4,640,803 acres were cultivated in 1876. As in England, and partly owing to the same causes, the quantity of wheat and other cereals grown is gradually diminishing. The division of the soil is greater than in England and Wales, but less than in Ireland. In 1877 the number of land-owners possessing more than an acre was 19,225, and of those possessing less than an acre was 132,230. (See also agriculture above, on page 470.)

### III. IRELAND.

This celebrated island is situated between lat.  $51^{\circ} 26'$  and  $55^{\circ} 21'$  N., lon.  $5^{\circ} 20'$  and  $10^{\circ} 26'$  E. It is rhomboidal in shape, and placed at the E. extremity of the Atlantic Ocean, which washes its N. W. and S. shores, while its E. coast is separated from the adjacent island of Great Britain by the Northern Channel, which at one point is only  $13\frac{1}{2}$  m. wide, the Irish Sea, about 130 m. in width, and St. George's Channel, which is 69 m. wide between Dublin and Holyhead, and somewhat less at its S. extremity. The largest diagonal line that can be drawn within the island, viz., from Tor Head, in Antrim, to Mizen Head, in Cork, measures 302 m.; and the shorter, from Carrisore, in Wexford, to Erris Head, in Mayo, is 210 m. in length. The breadth of the country, from Dundalk to Ballyshannon, is 85 m.; from Dublin to the head of Galway Bay, 110 m.; and the indentations of the coast by harbors, arms of the sea, and mouths of rivers are so numerous, that scarcely an acre of land in the country is more than 50 m. from the sea or good navigation. Area 31,874 sq. m., or 20,322,641 acres. If the possession of numerous fine bays and harbors made a country great as a commercial and maritime power, Ireland would be second to none in Europe. Pre-em-

Fig. 245. — LAND'S END.

the following as the estimated pop. of the 6 other principal towns in 1877: Glasgow, 555,933; Dundee, 142,951; Aberdeen, 98,181; Greenock, 70,192; Leith, 64,257; and Paisley, 48,679.

In 1877 the number of registered paupers and their dependants, exclusive of casual poor, who were in receipt of relief in parishes of Scotland, was 95,404, against 128,976 in 1868. The number of criminal offenders committed for trial was: men, 2,172; women, 505; total 2677, of which 2,010 were convicted. The following table gives the number of births, deaths, and marriages in each of the ten years 1868 to 1877:—

Years.	Population.	Births.	Deaths.	Marriages.
1868	3,188,125	115,673	69,396	21,853
1869	3,205,481	113,395	75,789	22,083
1870	3,222,837	115,423	74,067	23,788
1871	3,396,375	116,127	74,644	23,966
1872	3,399,226	118,873	75,741	25,580
1873	3,430,923	119,738	76,857	26,730
1874	3,442,916	123,795	80,676	26,247
1875	3,495,214	123,683	81,785	25,921
1876	3,527,811	126,749	74,122	26,563
1877	3,560,715	126,824	73,946	25,790

*Agriculture.* More than three fourths of the surface of the country is sterile, consisting of mountains, morasses, and

even in Ireland is the magnificent harbor of Cork, securely land-locked, protected by strong batteries, and used as the only naval station on the Irish coast. Baltimore Harbor, Skull, Cape Clear, Crookhaven, Dunmanus, and Bantry Bay are all of sufficient depth and capacity for large vessels. On the W. coast are Berehaven, Kenmare River, Valentia, Ventry, Smerwick, Brandon Bay, the estuary of the Shannon, Galway Bay, Roundstone Bay, Ardara or Clifden, Ballynakill and Killery Harbors, Clew, Blackrod, and Killala Bays, with many others of less importance. On the N. coast are Milroy Harbor, and the fine gulfs of Lough Swilly and Lough Foyle. The E. coast has been less favored by nature, and furnishes only one bay, with sufficient depth of water for the largest vessels, that of Strangford. The Bay of Dublin, which is much exposed, contains the fine artificial harbor of Kingstown. Belfast, Newry, Drogheda, Wicklow, Arklow, and Wexford have all been converted into ports, but are naturally deficient in the requisites for good harbors. Between Wexford and Cork is the fine Estuary of Waterford, formed by the confluence of the Rivers Suir, Nore, and Farrow. Altogether, Ireland possesses 14 harbors for the largest ships, 17 for frigates, from 30 to 40 for merchant-vessels, with many good summer roadsteads, and an infinity of small harbors for fishing-boats. The islands off the coast of Ireland are numerous, but generally of small size; the largest are Rathlin and Tory in the N.; Achill, Clare, the South Arran Islands, and Valentia, in the W.; and Whiddy and Cape Clear in the S. — *Surface.* As contrasted with Scotland, or even the greater part of England, Ireland may be said to be a flat country. Still, the surface is in parts much diversified; and even when it is quite flat, the

prospect is generally bounded by hills or mountains in the distance. The elevation of the surface of Ireland is stated in the following table from the Land Tenure Commissioners' map:—

	Square miles.
Between sea-level and 250 feet in height.....	13,242½
“ 250 and 500 feet.....	11,797½
“ 500 “ 1,000 “.....	5,797½
“ 1,000 “ 2,000 “.....	1,583½
Above 2,000 feet in height.....	82½
Total.....	32,500½

The highest peaks in the chief mountain groups are:—

	Feet.
Carntual, M'Gillieuddy's Reeks, Co. Kerry.....	3,414
Lugnaquilla, Wicklow.....	3,030
Slieve Donard, Mourne Mountains, Co. Down.....	2,796
Munrea, Co. Mayo.....	2,658
Comeeragh, Co. Waterford.....	2,557
Errigal, Co. Donegal.....	2,462
Trillick, Co. Antrim.....	1,810

Ireland was once so thickly covered with timber as to receive the name of the Island of the Woods. During the early periods of its connection with England its extensive and impenetrable forests formed a main obstacle to the progress of the English troops. Westminster Hall is said to be roofed with oak cut in the woods of Shillelagh. Numerous trunks of large trees are constantly found in the bogs. Even in mountain tracts, devoted for a long succession of years to the pasturage of sheep, timber-trees shoot up spontaneously wherever the land is secured from the intrusions of cattle. Many places, where the vestige of a plantation is not to be seen, retain names of which the word “wood” forms a component part; and in localities where the most attentive culture will not suffice to keep any tree or shrub alive on account of the western blasts, large trees are found embedded in the bogs. The different kinds of timber found in the bogs of Ireland are confined to oak, fir, yew, holly, sallow, and birch. Two centuries ago, when Ireland was covered with forests, there were numerous small iron-works, in which wood charcoal was employed, and vast quantities of wood used, until the country was gradually stripped of its supply, and the working of iron was consequently abandoned. The extension of agricultural improvement, and more especially the timber act, which gives the tenant, at the expiration of his lease, a pecuniary interest in the trees he has planted, are gradually removing this defect, the consequence of ages of disturbance and desolation; but trees in large quantities are generally found in Ireland only in the vicinity of the residences of the gentry, except in some favored spots, which are well wooded.—*Rivers and Lakes.* Ireland is plentifully watered, having to boast of an unusual number of rivers and inland areas of water. At the head of the former is the Shannon, which, as a channel of internal communication, is inferior to no river in the United Kingdom, being navigable for 214 m., or throughout the greater part of its entire course; the rivers next in magnitude and importance are the Barrow, Suir, Nore, Lee, Blackwater, Foyle, Slaney, Boyne, Bann, Kenmare, Moy, etc. Ireland is more remarkable for the number and extent of its lakes, or *loughs*, than either Scotland or England. Lough Neagh, in Ulster, extends over about 100,000 acres. Lough Erne, in county Fermanagh, consists of two considerable lakes connected by a winding strait, on an island of which the town of Enniskillen is built. Loughs Corril, Mask, and the exquisitely beautiful lakes of Killarney are the other principal sheets of water. The total superficies of the Irish lake-system is estimated at 455,390 acres, of which 32,474 acres are included in the province of Leinster, 44,652 in Munster, 183,795 in Ulster, and 194,477 in Connaught.

*Minerals.* Iron is found in many parts of the country; copper, lead, and sulphur mines occur in parts of Leinster and Munster; and gold and silver have been found in Wicklow. Copper, however, is the only metal which at present appears to be remuneratively raised; the ore is mostly sent to Wales for smelting. Antimony, manganese, serpentine of good quality, fuller's-earth, slate, gypsum, etc., with beryls and garnets, are the other chief mineral products. Several coal-fields exist, resting on a limestone basis. In Ulster, the district of Coal Island, in the county of Tyrone, produces coal of good quality, extensively used in the neighborhood; the small coal-field at Ballycastle, in Antrim, is of no economical importance. The prov. of Connaught affords beds of coal in Leitrim, Roscommon, and Sligo, but rarely exceeding three or four inches in thickness. The Munster coal-fields are in the counties of Cork, Kerry, and Limerick. The chief coal-district, however, is that of Leinster, in Carlow, Kilkenny, and the Queen's County. This coal, as well as that of the Munster district, is anthracituous; that of Connaught is bituminous. The native coal is only used in the districts where it is raised, and neither the quantity nor the quality has been found such as to interfere with the importation of coal from Great Britain, which probably exceeds 1,000,000 of tons annually. The deficiency of good coal is generally less felt as regards domestic than manufacturing purposes, about 2,800,000 acres, or nearly

1 part of the entire surface of the island, consisting of bog-land, which is capable of furnishing an almost inexhaustible supply of peat at very little more expense than that of the labor required in digging it. In not a few localities they have been wholly cut out, and when this is the case, and other bogs are not easily accessible, the inhabitants have suffered great privation from the want of fuel.—*Climate.* The climate of Ireland much resembles that of England, but rain is more frequent, and, even in the absence of rain, the atmosphere is largely impregnated with moisture. This circumstance, the result of the insular position of the country, and of the prevalence of the W. winds for three fourths of the year, accounts for the greater verdure of the island, and for the trees continuing much longer in leaf than in England. In the driest seasons Ireland rarely suffers from droughts, but the crops are often injured by too much wet. Hence, it is naturally much better adapted for a grazing than for an agricultural territory, and its superiority as a pastoral country was well known to the ancients.

The numbers of the population of the counties, cities, and towns of the 4 provinces of Ireland were found to be as follows at the census of 1871:—

Provinces, Counties, Cities, and Towns.	Population.		
	Males.	Females.	Total.
<i>Province of Leinster.</i>			
Carlow county.....	25,356	26,116	51,472

Total population.....	2,439,826	2,771,590	5,411,416
Population to the sq. m.....			169

Few countries in the world have increased in population so rapidly as Ireland during the first 40 years of the present, and the conclusion of the last century. Arthur Young, in his *Tour through Ireland*, in 1766, observed that it everywhere evinces the marks of a rapid increase of population. It is generally supposed that the number of the people increases in the ratio of food and comforts, and that an increase of population is a convincing proof of the advancing prosperity of a nation. The effect of the failure of the potato crop in depopulating the country would show that the population had outstripped the progress of wealth and the increase of industry, and had reduced their wants to the lowest point without procuring an addition to the comforts of life corresponding to the increase of the population. From 850,000 in 1652, the population rose to 2,317,384 in 1760; to 4,088,226 in 1792; to 5,387,556 in 1811; to 6,801,827 in 1821; to 7,767,401 in 1831; and to 8,175,124 in 1841. At the following census the population was found to have sunk to 6,552,336 in 1851; to 5,798,564 in 1861; and to 5,411,416 in 1871. From 1851 to 1875 the total emigration from Ireland was over 24 millions; and from 1820 to 1875 the emigration of Ireland to the U. States only was 3,031,451 (see EMIGRATION). The subjoined table gives the number of births, deaths, and marriages in each of the 8 years from 1870 to 1877:—

Years.	Population.	Births.	Deaths.	Marriages.
1870	5,412,660	150,151	90,695	28,835
1871	5,386,703	151,665	88,720	28,960
1872	5,366,696	149,292	97,577	27,114
1873	5,337,261	144,377	97,537	26,270
1874	5,314,844	141,288	91,961	24,481
1875	5,309,494	138,320	98,114	24,037
1876	5,321,618	140,433	92,324	26,388
1877	5,333,906	139,498	93,509	25,078

In 1878 the number of paupers in receipt of relief in unions was 85,530, against 74,743 in 1869. During the same year the number of criminal offenders committed was: men, 3,113; women, 758; total, 3,871; of which 2,303 were convicted.

**Agriculture.** The diversity of soils is not so great as in England. There are no stiff, clayey, or chalky deposits. Sandy soils are also rare. Loam, resting on a substratum of limestone, predominates; and though often very shallow, it is almost everywhere very prolific. In short, deducting the bogs and mountains, it is certain that this island is about the richest country, in respect of soil, in Europe. As a grazing country, it is probably superior to any in the Old World. The Agricultural Statistics of Ireland, issued from the General Register Office in 1878, show the number of acres under various crops as follows, in 1877 and 1878:—

Crops.	Acres in 1877.	Acres in 1878.
Wheat.....	129,297	154,011
Oats.....	1,476,172	1,412,637
Barley.....	226,216	243,929
Rye.....	11,124	11,439
Beans and pease.....	9,786	9,405
Potatoes.....	873,291	846,985
Turquoise.....	334,879	329,942
Mangel and beet roots.....	48,948	45,137
Cabbage.....	39,307	39,463
Carrots and other crops.....	34,750	35,161
Vetches and rape.....	34,834	21,022
Flax.....	123,380	111,808
Meadow and clover.....	1,924,917	1,942,716

The bulk of the population of Ireland depend for employment and subsistence on the soil. The competition for small patches of land is consequently very keen, and the rents greater than the occupiers can afford; though not greater than might be paid for them were they consolidated into proper sized farms, and cultivated on an improved system. In *I.*, in fact, the possession of a piece of ground has long been a condition all but indispensable to existence; and we need not, therefore, wonder that the occupiers should cling with desperate tenacity to their small patches. This has led in most parts to a sort of tacit but well-understood agreement among the cottiers or small farmers, to support each other against interlopers; and, in the greater part of the country, it is as necessary to the quiet possession of the land to secure what is called *tenant-right*, or the good-will of the occupier, as it is to make a bargain with the landlord. Any tenant who should neglect this indispensable precaution would run a great risk of being disturbed in, or forcibly ousted from, his holding. Indeed, most of the agrarian outrages which have for so long agitated the country have been directly or indirectly connected with land-occupancy. It is not necessary to enter into

any lengthened disquisitions as to the various circumstances which have led to that minute parceling of the land which is the *bane* of *I.* The greatest influence is, doubtless, to be ascribed to the custom of providing for the sons, and sometimes, also, the daughters of the occupiers of land, by giving them shares of their father's holdings. A good deal of what is peculiar in the mode of occupying land in this island has grown out of the conditions under which it was originally acquired by the ancestors of its present owners. About  $\frac{2}{3}$  of the soil was forfeited under Cromwell and William III.; and this amount of real estate was, for the most part, either gratuitously granted to, or was acquired at a nominal rate of purchase by noblemen and gentlemen of fortune and influence in England. Such persons could not be expected to leave their country to reside permanently in *I.*; and, in point of fact, they but rarely visited their Irish estates, but satisfied themselves with the acquisition of what rents they could get for them. No sympathy existed between them and their tenants; the religious and political principles of the one party were diametrically in antagonism to those of the other. The landlords looked upon their tenants as a sort of unwilling bondsmen, who, if any favorable opportunity should present itself, would immediately shake off their dependence on them; and, on the other hand, the tenants regarded the landlords as usurpers of an alien race unjustly intruded on the properties of others, and as enemies to the religion and rights of the Irish people. Very few had any confidence in the stability of such a state of things; and it could not be expected that landlords should care much about the permanent interests of their estates, or that they should lay out any considerable sum on their improvement. To build a farm-house or out-offices was an outlay which, for a lengthened period, no Irish landlord ever incurred; and even to this day the old habit maintains an ascendancy, and the great majority of land owners lay out little or nothing on buildings. Generally speaking, what are called farm-houses and out-buildings in England do not exist in Ireland; and the aspect of the *cabins*, or cottages, which, in the vast majority of instances, are of the most ramshackle description; the smallness of the fields, which, instead of hedges and ditches, or stone fences, are usually divided by turf dykes; and the poverty of the house furniture, and of the agricultural implements,—all impress one with most unfavorable convictions. But, how mortifying soever the contrast between the fertility of the soil and the condition of its occupiers, it is some satisfaction to remark that it is less striking now than formerly. In many districts a considerable change has been made towards a better state of things; but the evil is still far from being at its end, as exemplified by the violent agrarian agitation which took place in 1879, caused by the tenacity of landlords in exacting rents that the poor Irish tenants could not possibly pay, the failure of the crops in that year having led the agricultural population almost to starvation.

#### IV. MINES AND MANUFACTURES.

Next to agriculture, the material resources of *G. B.* and more especially of England, lie in its minerals. In the "Mineral Statistics of the United Kingdom," published in 1877, by the keeper of mining records, the mineral produce of *G. B.* is summarized as follows:—

Minerals.	Quantities.		Value.
	Tons.	Cwts.	£
Coal.....	133,344,766	0	46,670,668
Iron ore.....	16,841,583	14	6,825,705
Copper ore.....	79,252	0	317,186
Tin ore.....	13,688	9	600,923
Lead ore.....	79,096	6	1,218,078
Zinc ore.....	28,613	8	90,142
Iron pyrites.....	48,809	14	43,570
Arsenic.....	4,228	1	28,092
Manganese.....	2,796	17	9,783
Ochre and umber.....	3,805	4	4,478
Wolfram.....	23	10	172
Fluor spar.....	337	10	230
Clays.....	8,971,123	0	744,224
Oil shales.....	610,785	0	319,853
Salt.....	2,273,256	0	1,133,628
Barytes.....	23,561	18	24,479
Coprolites.....	258,150	0	625,000
Gypsum.....	61,741	0	13,571
Sundry minerals, including } China stone.....	.....		13,850
Total value of minerals produced in 1876.... }			58,691,832
			\$293,459,100

Under another calculation, the keeper of mining records gives the following summary of the total value of minerals, together with metals, obtained from the mines of the United Kingdom in 1876:—

Coal .....	£46,670,663
Metals, obtained from ores .....	18,968,818
Earthy and other minerals .....	2,887,367
<b>Total value .....</b>	<b>£68,226,853</b>

The metals obtained from ores are classified as follows, according to quantities and value, in 1876:—

Metals.	Quantities.	Value.
	Tons.	£
Pig-iron .....	6,555,997	16,062,192
Lead .....	58,667	1,270,415
Tin .....	8,500	675,750
Copper .....	4,694	392,300
Zinc .....	6,641	158,011
	Ounces.	
Silver .....	483,422	105,262
Gold .....	293	1,138
Other metals .....	.....	2,750
<b>Total value .....</b>	<b>.....</b>	<b>18,968,818</b>

It will be seen by a glance at the preceding tables, that the mineral wealth of *G. B.* lies, in substance, in two articles, namely, coal and iron ore. From these springs, as immediate produce, a third, namely, pig-iron. Coal and iron ore together form, as regards value, over  $\frac{2}{3}$  of the mineral produce; while pig-iron by itself holds nearly the same position in value among the metals produced in *G. B.*—*Coal.* In the production of the by far most important article of *G. B.*'s mineral wealth, to which all others are but appendages, England and Wales stand foremost to such an extent as to throw the other two divisions of the United Kingdom into comparative insignificance. To the total coal produce of *G. B.*, in the year 1876, England and Wales contributed 114,554,278 tons, being  $\frac{3}{4}$  of the whole. The remainder, 18,790,488 tons, was produced almost entirely in Scotland,—the mines of East Scotland furnishing 11,667,648 tons, and those of West Scotland 6,997,904 tons. The production of coal in Ireland in 1876 was not more than 124,935 tons. The gradual rise in production and value of coal is indicated in the subjoined table:—

Years.	Quantities.	Value.
	Tons.	£
1855	61,453,079	16,113,267
1858	65,008,649	16,252,162
1861	83,635,214	20,908,803
1864	92,787,873	23,197,968
1867	104,500,480	26,125,145
1870	110,431,192	27,607,798
1873	127,016,747	47,631,280
1876	133,344,766	49,670,668

The production of coal in *G. B.* was more than doubled in the period from 1855 to 1876, but the exports to foreign countries during the same time increased nearly eight-fold. From 4,976,902 tons in 1855 the exports rose to 9,170,477 tons in 1865, and to 11,702,649 tons in 1870. They further rose to 13,198,494 tons in 1872, to 13,927,205 tons in 1874, to 14,544,915 tons in 1875, and to 16,209,077 tons in 1876. Of the total exports of the year 1876 France took 3,160,555 tons, Germany 2,243,722 tons, and Italy, Russia, and Sweden and Norway, each a little over a million tons, the remainder being distributed over thirty other foreign countries and British colonies. Vast as has been the amount of the coal exports in recent years, they still represent less than  $\frac{1}{4}$  of the coal produce of the country. It is an admitted fact that the price of coal, which in recent years has been gradually rising in England, must continue to rise, both on account of its increased consumption, and of the constantly growing expenses of raising it. Although the total area of the coal-fields of *G. B.* extends, according to the most authentic estimates, over 5,400 sq. m., comparatively few new pits have been opened in recent years; and the ever-increasing demand has been supplied by the deepening as well as widening of the best collieries. This could only be achieved at an increased outlay, inasmuch as the cost of raising coal to the surface, and the attendant expenses of administration and supervision, are far greater than the cost of the actual displacement of the material from its beds. (See also *Coal*, page 176.)

*Iron Ore and Pig-Iron.* Though vastly inferior, as a source of national wealth, to coal, and deriving nearly all its value from it, still the second most important produce of English mines, the iron ore, has the greatest effect upon the industrial character of the country. England and Wales alone produce iron ore, the amount raised in Scotland and Ireland being quite insignificant. It amounted in Scotland to 5,226 tons, valued at £3,432 (£17,160), and in Ireland to 116,066 tons,

valued at £60,748 (£303,740) in 1876. The whole of the rest of the produce of *G. B.*, 16,720,291 tons, valued at £26,761,525 (£33,807,625), was raised in England and Wales. The pig-iron produced in *G. B.* in the year 1876 came from 17,813,818 tons of iron, of which amount 16,841,583 tons were raised at home, and the remainder, 972,235 tons, imported from foreign countries, principally from Italy, Spain, and Portugal. The following table exhibits the quantities and value of pig-iron produced in *G. B.* in every third year from 1855 to 1876:—

Years.	Quantities.	Value.
	Tons.	£
1855	3,218,154	8,045,385
1858	3,456,064	8,640,160
1861	3,712,300	9,280,975
1864	4,767,951	11,919,877
1867	4,761,023	11,492,557
1870	5,993,515	14,308,787
1873	6,566,451	18,667,739
1876	6,555,997	16,062,192

The iron manufacture is not in a prosperous condition. In 1877 the total number of existing furnaces in England was 626, and in Wales, 145; while the total number of active iron-works amounted only to 159 in England, and 24 in Wales, showing that more than three quarters of the furnaces were standing idle.

*Lead.* In comparison with coal and iron, all the other mineral products of the country are of small importance. Of these minor products, the highest on the list, as to value, is lead ore, raised in *G. B.* to the value of £1,218,078 in 1876, and producing lead valued at £1,270,415 (£6,352,075). The quantities of lead ore raised in the year amounted to 79,696 tons, and the metallic produce to 58,667 tons. Of this total, 73,361 tons of ore were raised in England and Wales, producing 54,293 tons of lead. More than one half of the lead ore and lead produced in England came from the counties of Durham and Northumberland, while two thirds of the produce of Wales came from Montgomeryshire and Cardiganshire. There were altogether 392 lead-mines in *G. B.* in 1876, and of this number 387 were in England and Wales. The produce of the lead-mines, after remaining stationary for many years, has, of late, declined considerably. In the fifteen years from 1854 to 1868 the average annual produce in *G. B.* amounted to about 68,000 tons. The culminating point of production was reached in the year 1870, with 73,420 tons, after which there was a steady falling off. The decrease in the home produce of lead was accompanied by an increase in the imports of the metal, which amounted to 61,987 tons in 1874, and rose to 79,825 tons in 1875, and to 80,649 tons, valued at £1,749,978 (£8,749,890), in 1876. It will be seen that the imports of lead are considerably larger than the home production.

*Tin.* Tin ore is found nowhere but in Cornwall and Devonshire, and in 1877 there were returned, as existing in England, 135 tin-mines. Their produce has suffered a great and steady decrease in recent years. In 1872 there were raised 14,296 tons of ore, producing 9,560 tons of metal, valued at £1,459,900; while the year 1876 showed a falling off to 13,688 tons, producing 8,500 tons of metal, valued at £675,750 (£3,378,750). During the same period the imports of tin, in blocks and ingots, from foreign countries gradually increased. They amounted to 166,840 cwt., valued at £1,154,578 (£5,772,890) in 1872, and rose to 304,551 cwt., valued at £1,148,542 (£5,742,710) in 1876. It will be seen that while the total quantity of tin imported within the quinquennial period underwent a considerable increase, the total value not only did not augment, but actually decreased. The decline in price was probably one of the main causes of the decline in the production of tin.

*Copper.* Next to tin in value stands copper. The total value of copper ore raised in *G. B.* in 1876 was 79,252 tons, of which 71,756 tons were the produce of England and Wales, while 680 tons came from Scotland, and 6,816 tons from Ireland. The total amount of the metal produced from the ores was 4,694 tons, valued at £392,300 (£1,961,500). In 1855 the total produce of copper was as high as 21,294 tons, valued at £3,042,877 (£15,214,385); from that time the quantity has been gradually declining, and, as with lead and tin, the copper imports grew largely while the production diminished.

*Salt and clay.* The centre of the salt production in England is in Cheshire, Norwich, Middlewich, Winsford, and other places, but there are also salt-mines in Staffordshire and Worcestershire. In 1876 the total quantity of salt raised amounted to 2,273,256 tons, valued at £1,136,628 (£5,683,140), of which 854,538 tons, valued at £523,547 (£2,647,735), were exported to foreign countries, chiefly to the U. S. States and British India. Of clays of all kinds, the total produce in 1876 was 3,371,123 tons, valued at £744,224 (£3,721,120). The finest of the clays, known as kaolin, or porcelain clay, is the produce of Cornwall and Devonshire, the former county raising 105,275

tons, and the latter 25,000 tons, in 1876. Of importance next to it, as potter's material, is the "Poole clay" of Dorsetshire, of which 72,105 tons were produced in 1876. Raised in much larger quantities than both the kaolin and the "Poole," are the fire-clays, the production of which in the year 1876 amounted to 1,514,902 tons. The fire-clays are found chiefly in the north and west of England and in South Wales.

*Cotton.* The following table shows the progress, with fluctuations, of the cotton-trade, in the annual imports, the exports, and the excess of imports of raw cotton during each, for every fifth year from 1841 to 1876:—

Years.	Total Imports of raw Cotton.	Total Exports of raw Cotton.	Excess of Imports.
	lbs.	lbs.	lbs.
1841	487,992,355	37,673,585	450,318,770
1846	467,856,274	65,980,732	401,875,542
1851	757,379,749	111,980,334	645,399,355
1856	1,023,886,304	146,660,854	877,225,440
1861	1,256,984,736	238,287,920	958,696,816
1866	1,377,514,096	358,981,333	988,532,760
1871	1,778,133,776	362,075,616	1,416,064,160
1876	1,487,858,848	203,305,872	1,284,552,976

There were 2,655 cotton factories in the United Kingdom at the end of 1874. They had 41,881,789 spindles and 463,118 power-looms, and gave employment to 479,515 persons, of whom 187,620 were males, and 291,895 females. Lancashire alone

Years.	Total Imports of Wool.	Total Exports (foreign and colonial).	Net Imports.
	lbs.	lbs.	lbs.
1841	59,170,974	2,553,671	53,617,303
1846	65,255,462	3,011,980	62,243,482
1851	83,311,975	13,729,987	69,581,988
1856	116,211,392	26,679,793	89,531,599
1861	147,172,841	54,377,104	92,795,737
1866	239,358,689	66,573,488	172,785,201
1871	323,036,299	134,866,304	188,169,995
1876	390,053,759	178,020,372	217,033,387

Of the 1,800 woollen factories in existence in the United Kingdom at the end of 1874, England and Wales had 480; and of the 692 worsted factories, England and Wales had 239. The chief seat of the woollen and worsted manuf. in England is in Yorkshire, while Lancashire stands second, but a long way behind.

*Silk.* There were in 1876, in *G. B.*, 818 silk-factories, with 1,336,411 spindles and 10,002 power-looms, employing 45,559 persons. Of this total, only 4 factories, with 226 power-looms, employing 740 persons, were in Scotland; and but 2 factories, with 7 power-looms, employing 400 persons, were in Ireland.

*Linen.* In 1876 there were in *G. B.* 449 factories for spinning flax, using 1,473,800 spindles and 41,980 power-looms, and employing 128,459 hands. In the returns for 1874, Scotland took the first rank as regards the number of flax-factories, Ireland the second, and England the third rank. There were in Scotland at that date 159 factories, with 275,119 spindles and 18,529 power-looms, employing 45,816 persons; and in

Fig. 246.—COURTYARD, HADDON HALL.

absorbs three fourths of the manuf. of cotton fabrics in *G. B.*, having 1,911 factories, with 373,061 power-looms, and 352,003 persons employed. (For further information and statistics, see *Cotton*, page 23.)

*Woollen and Worsted.* There were in 1876, in *G. B.*, 1,800 woollen and 692 worsted factories. In the woollen factories there were in use 3,323,881 spindles and 57,090 power-looms, and they employed 131,605 persons; while in the worsted factories there were in use 2,382,450 spindles and 81,747 power-looms, and they employed 142,097 persons. Unlike cotton, the raw material for woollen fabrics is mainly produced at home; still, for many years past the native supply has been insufficient, which necessitated imports from foreign countries and British colonies, ever increasing in amount. During 1840–1876 the imports of wool rose from 49 to 390 millions of pounds.

The following table exhibits the imports of wool into *G. B.* from foreign countries and British colonies, the amount of re-exports, and the net balance of imports, for every fifth year from 1841 to 1876:—

Ireland 149 factories, with 906,946 spindles and 17,827 power-looms, employing 60,316 hands.

*Hosiery, Lace, and Shoddy.* There are enumerated in official returns a number of other existing factories, among them of hosiery, lace, "shoddy" hair, felt, and elastic fabrics. The hosiery factories of *G. B.* employed 11,980, and the lace factories 10,373 persons in 1874; but all the others gave employment, in the aggregate, to less than 9,000 workers. The hosiery factories were all in England, with the exception of 4 in Scotland, employing 1,006 persons. In the English hosiery factories, 65 in number, nearly all in Leicestershire and adjoining midland counties, there were 10,914 persons employed in 1874, about one half of them women. The hosiery factories of England more than doubled from 1861, when their number was 65, to 1874. The same was the case with the lace factories, which increased from 186 to 311 in 1874. Another notable textile industry enumerated in the official returns is that of "shoddy factories." There were of these establishments, 125 in *G. B.* in 1874, all of them in England, with the exception of some very small Scottish ones, returned as employing

together 7 persons. The English shoddy factories, dispersed in 1874 over Yorkshire and Lancashire, with but a few in other counties, had in use in that year 101,134 spindles and 1,437 power-looms, and employed 3,424 persons, more than one half of them women. There was an increase in the shoddy factories of Lancashire from 1868 to 1874, but a decrease during the same period in those of Yorkshire.

#### V. FOREIGN COMMERCE.

The most important fact in connection with the foreign commerce of *G. B.*, in recent years, is that there has been a gradual and steady increase of imports, together with a decrease of exports of home produce. The movement began in 1872. Up to that time the exports of British produce had kept on increasing with the imports, although at a lower rate, and far inferior in aggregate value; but a change took place in the latter year. While the imports have continued their upward course, the exports of British produce have fallen regularly and steadily down to the present time, and with a tendency to become more pronounced every year. The decline in exports affected all the principal articles of British home produce; it was greatest of all in textile manufactures, and least in coals and machinery. The declared value of imports and exports of *G. B.* during the ten years 1868 to 1877 was as follows:—

Years.	Total Imports.	Exports of British Produce.	Exports of Foreign and Colonial Produce.	Total Imports and Exports.
	£	£	£	£
1868	294,633,698	179,677,812	48,100,642	522,412,062
1869	295,499,214	189,933,957	47,061,665	532,455,236
1870	303,257,493	199,586,822	44,493,755	547,338,070
1871	331,016,380	223,006,102	60,508,538	614,530,040
1872	354,633,624	256,257,347	58,331,487	669,282,458
1873	371,287,372	255,104,693	55,840,102	682,292,137
1874	370,082,701	239,558,121	58,062,343	667,733,165
1875	373,939,577	223,465,993	58,146,399	655,551,969
1876	375,154,703	200,623,204	56,137,308	631,931,315
1877	394,419,682	198,893,065	53,452,955	646,765,702

The following table shows the relative division of the imports and exports of British produce in each of the years 1876 and 1877:—

COUNTRIES.	IMPORTS.		EXPORTS.	
	1876.	1877.	1876.	1877.
<b>I. FOREIGN COUNTRIES.</b>				
Russia.....	£17,574,000	£22,142,000	£6,183,000	£4,179,000

The six principal articles of British produce exported to colonial possessions and foreign countries in the years 1875, 1876, and 1877, were as follows : —

Principal articles.	1875.	1876.	1877.
1. Cotton manufactures : —	£	£	£
Piece goods, white or plain ..	33,255,013	31,454,280	31,809,747
“ printed or dyed ..	19,900,918	18,494,492	20,218,715
“ of other kinds ..	5,442,922	4,910,763	5,007,567
Cotton yarn .....	13,172,860	11,781,733	12,192,954
Total of cotton manuf. ....	71,771,713	67,641,268	69,226,983
2. Woollen and worsted man.			
Cloths, coatings, etc. ....	6,850,203	6,451,410	6,567,806
Flannels, blankets, and balzes .....	1,239,637	1,014,886	1,176,377
Worsted stuff .....	11,159,914	9,141,605	7,725,414
Carpets and druggets .....	1,159,979	911,873	847,763
All other sorts .....	1,249,592	1,083,704	1,025,843
Woollen and worsted yarn ..	5,059,307	4,417,241	3,909,456
Total of woollen and worsted manuf. ....	26,758,632	23,020,719	20,952,659

Principal articles.	1875.	1876.	1877.
3. Iron and steel : —	£	£	£
Iron, pig and puddled .....	3,449,916	2,842,434	2,528,655
“ bar, angle, bolt, and rod .....	2,725,907	1,945,445	1,928,103
“ railroad, of all sorts ..	5,453,836	3,700,105	3,868,106
“ wire .....	780,087	731,148	752,278
“ tinned plates .....	3,686,607	2,891,693	3,083,126
“ hoops and plates .....	3,304,148	2,853,621	2,732,313
“ wrought, of all sorts ..	4,342,492	4,041,418	3,645,661
“ old, for re-manuf. ....	102,837	95,977	100,758
Steel, wrought and unwrought .....	1,901,491	1,635,569	1,524,885
Total of iron and steel .....	25,747,271	20,737,410	20,113,915
4. Coals, cinders, and fuel .....	9,658,088	8,904,463	8,351,799
5. Linen manufactures : —			
White or plain .....	5,904,358	4,335,072	4,597,665
Printed, checked, or dyed ..	470,295	449,918	471,982
Of other sorts .....	897,667	805,746	764,796
Linen yarn .....	1,855,684	1,449,513	1,509,153
Total of linen manuf. ....	9,128,604	7,070,149	7,343,596
6. Machinery .....	9,058,647	7,210,426	6,722,868

The tendency of modern English legislation is towards concentration of customs duties on a few articles. At present there are virtually but four great articles of customs produce, namely, tobacco, spirits, tea, and wine. The receipts of the customs were as follows in each of the years 1876 and 1877 : —

Articles.	Gross produce of customs duties.	
	1876.	1877.
	£	£
Chicory .....	62,889	66,004
Cocoa, cocoa-husks, and chocolate .....	44,953	43,508
Coffee .....	208,467	205,272
Fruit, dried : currants .....	340,179	286,114
“ figs, plums, and prunes ..	44,506	40,190
“ raisins .....	150,434	152,649
Spirits : rum .....	2,554,260	2,509,775
“ brandy .....	2,341,120	2,135,135
“ geneva and other sorts ..	1,065,157	865,228

	\$100,273,490	\$98,681,055

The decline of English manufacture and commerce may be attributed partly to the badness of English work and partly to the faults both of master and man, which have caused the high price of production. To these should be added certain results of the existing laws of England, which necessarily affect the price of production. One of those is the *high price of land*, arising from its absorption by a few owners (see above), which results in increased rents for manufacturers, and, therefore, in the necessity of selling a much larger quantity of goods before any actual profit can be made. Here, France, Germany, and Belgium — without for the present speaking of this country — have the advantage over England. The delegates of the British Chamber of Commerce who went to France, in 1879, to report on the French industries in view of the prospective revision of the French tariff, found that the French woollen mills, for instance, could be erected for less money than English, and that though the machinery and fuel may be dearer, the mode of working is much more economical. French mill-hands work as a rule 72 hours a week instead of 56½, as in England, and receive for that in some cases only \$100 where \$200 would be paid in England, while \$150 to \$200 is a very common difference. Quite as much work in the time is got out of the French workman as out of the English, and as regards managers, overlookers, designers, dyers, and foremen, the French have the advantage, as they are better educated and have a more cultivated taste than the corresponding classes of English artisans. The chief fault of the manufacturers is their *conservatism*. They prefer to stick to old processes and

old models, and are unwilling to please or suit the tastes of their customers. They seem to forget that variety is the order of the day, and that in stuffs nothing remains in fashion long. They have shown more yieldingness in the patterns of stuffs which they have made for the Eastern and Asiatic markets; but even here they have tried too much to impose their own ideas on the natives, and Russian and German goods at the same price are usually preferred, and in some cases even sell at higher prices. The French are much quicker to catch the feeling of change in the air, either by taking advantage of a pattern which is about to prevail or to introduce one. The consequence is that French manufacturers are constantly making slight alterations in their machinery, by which they produce new stuffs; and the world is now so united that what is the fashion in France speedily becomes so in England. English manufacturers, on the contrary, look to the great cost which would be incurred by changing their machinery, and frequently continue producing articles which do not sell at the time in the hope that some day they may again satisfy public taste. Another example of the conservatism of the English manufacturer is manifested in the preference for hand

high for the times — and a decrease of working hours. During the time when trade was particularly flourishing, and when nearly all the manufacturers were making money, many employers of labor gave bonuses to their workmen, which they now find it impossible to continue. This has caused discontent among the workmen, who cannot see why they should not receive the same pay in bad times as in good. Where they refuse to accept a reduced scale of wages it necessitates either the closing of the factories or the reduction of the working time per week; it is found impossible to gain profits by making the usual quantity of goods in a dull time with such high wages for the production of them. In many cases it is a small section of the workmen who thus close the mills and throw very many others out of employment. If, for instance, spinners in a cotton-mill strike, there is nothing for the weavers to do, and no use of the preparers working. The whole business must come to a standstill. While philanthropists everywhere have supported the *short hour movement*, — on the ground that it affords laborers an opportunity for recreation and self-improvement — they have not noticed that the ultimate consequences have been worse for the laborer, who does

Fig. 247. — MOUTH OF THE AVON.

work to machine work. In many respects hand labor is superior to machine labor, where it is perfectly well done. But in cases where hand labor is thoroughly well performed the articles become too expensive to compete with those of a similar kind made by machinery. The excellence of machine work is exemplified in the manufacture of watches made by this method, and which are so good as to be equal, if not superior, to the very best hand work; and in the ordinary articles made by hand, especially in the metal works, there is a great deal of "scamping," and there is also a "roughness" and an inelegance which do not appear in the machine-made articles. Articles made by hand may be, though they are not really always, more durable than those produced by machinery; but modern life is such that there are many things in common use which are perhaps better for not being too durable at the expense of elegance and convenience. One great obstacle to the efficiency of labor, and consequently to good work and cheap work, is the existence of *trade-unions*. Now, of course, no one wishes the men to get less for their work than they can, or that can be properly paid to them, having regard to the interests of all. But at the same time life is a constant struggle for existence and this is nowhere more noticeable than in the competition of manufacturers. Trade-unions, therefore, by disorganizing labor, by preventing men from working who are willing to do so because they are thrifty and live for less than men who drink and squander away their wages, by insisting upon bad workmen being paid the same wages as good men, increase the cost of production in countries where they exist, as compared with others where there are no such combinations, and in that way finally do harm to the very people whom at first they appear to benefit. Trade-unions in England have brought about high wages — far too

not, as a general rule, devote the hours which were formerly occupied with work in purposes of self-improvement, but, at all events in England, has passed them in idleness or dissipation. With the rest of the world working 11 or 12 hours a day, it is impossible for the English laborers to work 9 or 10, and in any successful degree compete with their rival artisans. The normal time of working is now 10 hours a day in most factories, and 6 hours a day in coal pits and mines. But at present, owing to the small amount of manufacturing going on, these hours are very much shortened, and in many cases they are reduced by the men themselves, who, besides very frequently refusing to work on Mondays, — not having sufficiently recovered from their debauch of the day before, — constantly remain away for a week at a time. Saturday, too, is a half-holiday, when not more than 6½ hours can be required. Continental workmen work regularly 12 hours a day, six days in the week, and by a proportionate increase of pay can be induced to work over hours and on Sundays. The English workman is too generally obstinate, idle, drunken, unwilling to adopt new ideas, and seems to try to do the minimum of work in the maximum of time. One of the worst results of the difficulties between masters and men has been occasioned by the introduction of "piece work," which at first appeared favorable for both parties, inasmuch as it enabled the employer to pay for no more work than was absolutely done, and, on the other hand, induced the men to be more industrious through a desire to finish one piece and be paid for it, instead of simply working on time. Now, however, it seems to be admitted that though in some cases it would be difficult to return to the previous system, piece work is almost always uniformly bad. It is found especially in the manufacture of prints and stuffs that the work is much worse done than under the old system,

although there may be more of it. Under the time system the workman was always willing to stop the machine to correct flaws and take up threads, whereas under the piece system not even the strictest surveillance is capable of making him do this. He is anxious to get through his quantity, and stopping the machine would delay him, and he cares little what the quality of his work may be. We have spoken of the heaviness, ugliness, and want of finish of the English work; but the greatest objection now urged against English manufactures is their actual badness. Cotton goods are made with so much *size* that they will scarcely bear being washed once, and, as was seen by a recent legal trial in London, become mildewed and spoiled in the course of a journey from England to China. Formerly the size was 10 per cent of the stuff in cotton goods; now it is 72 per cent. Woollen goods are made in the same bad way, the thread being rough and coarse and filled in with *shoddy*. And the worst of it is that the English laws are so peculiar that it is difficult to find any remedy.

This country seems marked out by nature for the industrial supremacy which has so long been held by G. B. Her peerless position as queen of the seas has contributed, in no small degree, to her industrial supremacy; but the U. States could in a few years dwarf her to a subordinate rank as a manufacturing nation, if we possessed her established lines of communication with all parts of the world, and her consequent cheap access to every important market. In order to command distant markets, two things are necessary, — first, the ability to produce cheap goods, and second, cheap transportation. We are already abreast of England in the cheapness, and ahead of her in the quality of our manufactures; but the abundance of her shipping, and the regularity and frequency of her great lines of steamships, make their trips to all markets of any consequence, to undersell us in many markets, and may continue to do so for some time to come. American cotton fabrics laid

down on a wharf at Boston are cheaper (quality being compared with quality) than British cotton fabrics laid down at a wharf at Liverpool; but the Liverpool shipper pays, on an average, not more than half the amount of freight which it costs the Boston shipper to transport his goods to distant markets. But even with the great disadvantage of our crippled navigation interest, we are, to use Mr. Gladstone's striking expression in his "Kin Beyond the Sea" pamphlet, passing British industry "on a canter." We are effectually shutting her out of our own extensive market, — the most valuable single market she ever possessed, — shutting her out by the achieved excellence and cheapness of our manufactures in cotton, in wool, in leather, in iron, in tools, machinery, and agricultural implements. English political economists say that the loss of our markets for England is owing to our high tariff. It may be partly true, but the best reason is that we have come to make better goods, and are able to sell them at prices with which she cannot compete. The U. States market is irretrievably lost to her, thanks to the inventive skill of our mechanicians, the abundance of our native raw materials, the new economies practised by our mill-owners, the excellence of our products, and their better adaptation to the wants of our own consumers.

#### VI. SHIPPING.

The shipping of G. B. increased sixfold in the period from 1840 to 1877. In the year 1840 the total tonnage of the vessels, British and foreign, which entered at ports of G. B. was 4,657,795; and in the year 1850 it had risen to 7,100,476, while in 1860 the total tonnage was 12,172,765. The rise continued uninterrupted, as will be seen from the following table, which shows that the number and tonnage of sailing vessels is proportionally decreasing, and that of steamers increasing to such an extent that steam vessels appear likely to absorb the whole international commerce of the country: —

YEARS.	ENTERED.			CLEARED.		
	British.	Foreign.	Total.	British.	Foreign.	Total.
1. Total number entered and cleared: —						
1890.....	6,888,000	5,284,000	12,172,000	7,026,000	5,491,000	12,516,000

Total.....	383	469,854	515	650,169

*Ship-building* has long been an industry of great importance in *G. B.*, although of late years it has suffered considerable fluctuations. The principal centres of the industry in England are the Thames, the Tees, the Tyne, and Sunderland on the east coast, and Liverpool, Barrow, and Whitehaven on the west. A very large proportion of vessels built in recent years are constructed of iron, with the consequence that the ship-building trade has mostly settled in those parts of the coast that are nearest to the iron and coal fields. In 1874 the total amount of shipping built in England reached 277,984 tons; in 1875, 220,036 tons; and in 1876, 189,840 tons. In Scotland there were built 166,214 tons, and in Ireland 4,311 tons, in 1876. The numbers do not include ships built on foreign account.

#### VII. RAILROADS.

From the opening of the first railroad, in 1825, till the end of 1850, a period of a quarter of a century, 6,621 m. of lines were constructed in *G. B.*, being at the rate of 265 m. per annum. At the end of 1860 the length of lines opened for traffic was 10,433, showing an increase of construction at the rate of 351 m. per annum. In 1878 there were 16,872 m. open for traffic, the increase presenting an average of 410 m. per annum of the total length. Of the total length of lines open in 1878 there belonged to England and Wales 11,989 m., to Scotland 2,726 m., and to Ireland 2,157 m. The following table gives the length of lines open, the capital paid up, the number of passengers conveyed, and the traffic receipts of all the railways of *G. B.* in each of the ten years from 1868 to 1877:—

Years	Length of lines open at the end of each year.	Total capital paid up (shares and loans) at the end of each year.	Number of passengers conveyed (exclusive of season-ticket holders).		Traffic receipts.	
			Total.		Total.	
	Miles.	£	No.	Pr. m.	£	£
1868...	14,628	511,680,855	304,136,334	21,961	40,912,534	2,875
1869...	15,145	518,779,761	305,664,285	20,189	42,695,321	2,712
1870...	15,537	529,908,673	330,004,398	21,518	45,078,143	2,794
1871...	15,756	552,680,107	375,220,754	24,025	48,892,780	3,063
1872...	15,814	569,047,346	422,874,822	26,740	51,304,114	3,244
1873...	16,082	588,320,308	455,320,288	28,332	55,675,421	3,462
1874...	16,449	609,895,919	478,316,701	29,080	56,901,281	3,459
1875...	16,653	630,226,942	507,532,187	30,470	58,982,753	3,541
1876...	16,872	658,214,776	538,681,722	31,928	59,917,868	3,551
1877...	17,077	674,069,048	561,593,654	32,301	62,973,328	3,637

To the total capital in 1877 England and Wales contributed £557,878,925, Scotland £84,924,763, and Ireland £31,255,360. In the division of the traffic receipts of 1877, England and Wales took £53,057,499, Scotland £7,110,228, and Ireland £2,805,601. The working expenditure amounted to £23,857,978 on all the railroads in 1877, being 54 per cent of the total traffic receipts. The following tabular statement gives the total length of railroads open for traffic in the British Empire at the beginning of 1878:—

	Miles.	Miles.
United Kingdom.....	7,824	17,092
India.....	92	.....
Ceylon.....	5,674	.....

Total of Colonial Empire of Great Britain 16,820

Total, British Empire..... 33,412

The construction of railroads in England was undertaken originally by a vast number of small companies, each obtaining separate acts of Parliament deemed requisite for their existence. But many years did not elapse before it was discovered that there could be neither harmonious nor profitable working of a great many systems, and this led to a series of amalgamations, by which the majority of the lines were brought under the management of a few great corporations. In the official "Railway Returns," issued by the Board of Trade, there were still 92 independent companies enumerated as existing in England and Wales in 1877, but the mass of these consisted of very small undertakings. Virtually the railroads of the country were controlled by seven leading companies, as follows:—

RAILROAD COMPANIES	Seat of Management.	Length of System, 1877.
		Miles.
Great Western.....	London.....	2,058
London and Northwestern.....	London.....	1,632
Northeastern.....	York.....	1,429
Midland.....	Derby.....	1,238
Great Eastern.....	London.....	859
London and Southwestern.....	London.....	687
Great Northern.....	London.....	640

The seven great railroad companies here enumerated—which might be reduced to six, the Northeastern and Great Northern practically forming a united system—held between them 8,543 m in 1877, representing nearly all the main lines of the country. It seems probable that, with the exception, perhaps, of two or three companies south of the Thames, possessing, in the communication with the continent, an independent traffic, all the others will gradually follow the process of absorption, more and more strongly developed in recent years. It may be that the process will ultimately reach its furthest solution by all the railroads being placed by purchase, the same as the telegraphs, under the sole control of the government.

#### VIII. FINANCES.

The finances of *G. B.* are in the most satisfactory condition. Not only is the national revenue requisite to meet the expenditure raised with the utmost facility, but for many years the balance of them has been complete, an annual surplus being the rule, and a deficit the exception, in most financial periods. The subjoined table shows the total revenue and expenditure of the government, together with the proportion of receipts per head of population of the United Kingdom, in every fifth financial year from 1841 to 1871, and each year thereafter to 1878:—

Years.	Total revenue.	Total expenditure.	Proportion of revenue per head of population.		
	£	£	£	s.	d.
1841.....	47,433,359	49,285,396	1	15	9
1846.....	52,009,324	49,528,724	1	17	5
1851.....	53,057,053	49,882,322	1	18	6
1856.....	65,704,491	88,428,345	2	10	7
1861.....	70,283,674	72,792,059	2	8	10
1866.....	67,812,292	65,914,357	2	5	1
1871.....	69,945,220	69,548,539	2	4	5
1872.....	74,708,314	71,490,020	2	7	3
1873.....	76,608,770	70,714,448	2	8	2
1874.....	77,335,657	76,466,510	2	8	2
1875.....	74,921,873	74,328,040	2	6	3
1876.....	77,131,693	76,621,773	2	7	1
1877.....	78,565,036	78,125,227	2	7	6
1878.....	79,763,299	78,903,495	2	7	8

The following table gives the official account of the gross sources of revenue for the financial year 1878:—

Revenue.	Expenditure.
Customs.....£19,969,000	National Debt.....£28,000,000
Excise.....27,464,000	Floating Debt.....411,923
Stamps.....10,956,000	Civil List.....406,710
Land Tax, etc.....2,670,000	Other Charges.....1,234,875
Income Tax.....5,820,000	Army.....14,607,445
Post-Office.....6,150,000	Army Purchase.....504,720
Telegraphs.....1,310,000	India Charges.....1,000,000
Crown Lands.....410,000	Navy.....10,978,592

Miscellaneous.....4,064,415	Customs and Collection.....2,688,267
Total.....£79,763,299	Post-Office.....3,185,346
£398,816,495	Packet Service.....763,000
	Telegraphs.....1,157,000
	Total.....£78,903,495
	£394,517,475

About three-fourths of the total revenue of G. B. are derived from three sources of income,—excise, customs duties, and stamps. In the sixteen financial years from 1862 to 1877, the revenue from the excise increased greatly, and that from customs declined, while that from stamps increased moderately. The following table shows the receipts from these main sources of revenue for every third year from 1867 to 1877:—

Years.	Excise.	Customs.	Stamps.
	£	£	£
1862.....	18,332,000	23,674,000	8,590,945
1865.....	19,555,000	22,572,000	9,530,000
1868.....	20,162,000	22,650,000	9,541,000
1871.....	22,783,000	20,191,000	9,007,000
1874.....	27,172,000	20,339,000	10,550,000
1877.....	27,736,000	19,922,000	10,890,000

**Excise.** The vast increase in the receipts from the excise was due solely to the corresponding increase in the consumption of spirituous liquors. The increase was greatest in the receipts from spirits, which rose from £9,618,291 (£48,091,455) in 1862 to £14,873,165 (£74,355,325) in 1877. The excise receipts from malt grew from £5,866,302 (£29,331,510) in 1862 to £8,040,378 (£40,201,890); and those from licenses to make and sell spirits and malt liquors from £1,500,613 (£7,603,065) in 1862 to £3,549,557 (£17,742,785). In the latter financial year the receipts from the excise had come to represent already considerably more than one third of the total revenue, and should the growth, very steady and regular from year to year, continue at the rate shown in the preceding table, it will not be long before one half of the national income will be raised by the voluntary taxation of the consumers of alcoholic liquors.

**Customs.** The decline in the receipts from customs during the period 1862 to 1877 was mainly due to a constant reduction of duties. Those of tea were reduced in 1862, causing a loss to the revenue of £1,641,541; and again in 1864, when the loss was £2,214,981. The duties on sugar were also greatly reduced in 1863, the loss to the customs being £1,741,272; and again in 1872, with a loss of £1,612,582; while the small remnant of the old duties on corn was repealed in 1868, at a loss of £855,581; and the example was followed in the case of the sugar duties, the last of which was abolished in 1875. Thus the

sugar duties, producing £6,383,283 in 1862, brought nothing in 1877, while the tea duties fell from £5,516,584 to £3,723,147. Alone of all the customs duties, those on foreign spirits and wine increased during the period, notwithstanding the latter article also underwent a reduction of duties. Together, the foreign wine and spirits duties produced £3,753,785 in the financial year 1840–41, and £7,507,807 in 1876–77. Adding this sum to the excise receipts, the total revenue derived from spirituous liquors in the financial year 1877 was no less than £35,243,807 (£176,219,053), or nearly three sevenths of the national revenue.

The indication of the proportions of the revenue derived from taxation in England, Scotland, and Ireland respectively is shown in the following table. The figures, which are for the financial year 1877, do not include the post-office returns, and in the case of the income tax are exclusive of the returns from the incomes of government officials:—

Revenue, 1876–77.	England.	Scotland.	Ireland.
	£	£	£
Spirits.....	13,078,101	4,056,331	3,507,985
Malt.....	7,220,089	3,834,343	451,950
Wine and beer (customs).....	1,894,856	124,309	211,078
Excise licenses.....	3,094,395	3,958,590	205,593
Tobacco.....	6,014,114	737,227	1,024,234

Stamps.....	8,581,581	1,110,807	589,173
Miscellaneous items.....	1,324,787	77,910	10,208
Total.....	£51,101,890	£7,757,213	£6,664,724
Per head of pop.....	£2 1s. 8½d. \$10 4½	£2 3s. 6½d. \$10 8½	£1 4s. 11½d. \$6 23½

**National Debt.** Leaving alone the cost of the army and navy, the charges for the interest and management of the debt form by far the most important branch of national expenditure. The foundation of this debt, larger than that of any other country in the world, was laid at the time of the revolution, in 1689, and its growth since that time, both as regards capital and interest, is shown in the following table:—

Historical Periods.	Capital of Debt.	Interest and Management.
	£	£
Debt at the Revolution, in 1689	664,263	39,855
Excess of debt contracted during the reign of William III. above debt paid off.....	15,730,439	1,271,087

## IX. BANKING.

The *Bank of England*, which has long been the principal bank of deposit and circulation in *G. B.*, and indeed in Europe, was founded in 1694. Government being at that time much distressed for want of money, the bank grew out from a loan of £1,200,000 for the public service. The subscribers, besides receiving 8 per cent on the sum advanced as interest, and £4,000 a year as the expense of management, in all £100,000 a year, were incorporated into a society denominated the Governor and Company of the Bank of England. The charter is dated the 27th of July, 1694. It declares, among other things, that "the corporation is prohibited from engaging in any sort of commercial undertaking other than dealing in bills of exchange, and in gold and silver. It is authorized to advance money upon the security of goods or merchandise pledged to it, and to sell by public auction such goods as are not redeemed within a specified time." And in 1697 it was enacted, that the "common capital or principal stock, and also the real fund, of the governor and company, or any profit or produce to be made thereof, or arising thereby, shall be exempted of any rates, taxes, assessments, or impositions whatsoever during the continuance of the bank." The year 1708 is memorable in the history of the bank for the act declaring that during the continuance of the corporation of the Bank of England "it should not be lawful for any body politic, erected or to be erected, other than the said governor and company of the Bank of England, or of any other persons whatsoever, united or to be united in covenants or partnership, exceeding the number of six persons, in that part of *G. B.* called England, to borrow, owe, or take up any sum or sums of money on their bills or notes payable on demand, or in any less time than six months from the borrowing thereof." It will be seen on examination that the proviso did not prohibit the formation of associations for general banking business; it simply forbade the issue of notes by associations of more than six partners; but the issue of notes was regarded as so essential to the business of banking, that it came to be believed that joint-stock banking associations were absolutely prohibited in England, and no such association was founded until after the legislation of 1826, expressly permitting them to be established. The charter of the Bank of England, when first granted, was to continue for eleven years, certain, or till a year's notice after the 1st of August, 1706. The charter was further prolonged in 1697. In 1708, the bank, having advanced £400,000 for the public service, without interest, the exclusive privileges of the corporation were prolonged till 1763. And in consequence of various advances made at different times, the exclusive privileges of the bank were continued by successive renewals till the 5th of April, 1826. The capital of the bank on which dividends are paid has never exactly coincided with, though it has seldom differed very materially from, the permanent advance by the bank to the public. Between 1694 and 1727 it had increased to near £3,000,000. In 1746 it amounted to £10,780,000. From this period it underwent no change till 1782, when it was increased 8 per cent, amounting to £11,642,400. It continued stationary at this sum down to 1816, when it was raised to £14,553,000 (\$72,765,000), which is its actual amount.

In 1826 the law of 1708, limiting to six the number of partners in banking establishments issuing notes, was repealed; and it was enacted, that banks with any number of partners might be established for the issue of notes anywhere beyond

sixty-five miles from London, and that banks not issuing notes might be established in London itself with any number of partners. The circulation of notes for less than five pounds in England and Wales was at the same time forbidden. It was intended to extend the same prohibition to Scotland and Ireland, but the opposition to the proposal excited in these countries was too strong to be overcome. Very few joint-stock banks were set on foot for some years after the act permitting their establishment; but the mania for embarking in speculative schemes, which raged with violence during 1835 and part of 1836, extended to joint-stock banks, of which from about 220 to 280 were opened in England and Wales. At the beginning of 1836, when the rage for establishing joint-stock banks was at its height, the exchange was either at par, or slightly in our favor, showing that the currency was already up to its level, and that if any considerable additions were made to it, the exchange would be depressed, and a drain for bullion be experienced. But these circumstances, if ever they occurred to the managers of the joint-stock banks, do not seem to have had, and could not in truth be expected to have, any material influence over their proceedings. Their issues, which amounted on the 26th of December, 1835, to £2,799,551, amounted on the 25th of June, 1836, to £3,588,064, exclusive of the vast mass of additional bills, checks, and other substitutes for money they had put into circulation. The consequences were such as every man of sense might have foreseen. In April, 1836, the exchange became unfavorable, and bullion began to be demanded from the Bank of England. The directors, that they might the better meet the drain, raised the rate of interest in June from 4 to 4½ per cent, and this not being enough sufficiently to lessen the pressure on the bank for discounts, they raised it in August from 4½ to 5 per cent. But during the whole of this period the country banks went on increasing their issues; and the issues of the joint-stock banks rose from £3,588,064 in June, to no less than £4,258,197 on the 31st of December, being an increase of nearly 20 per cent after the exchange was notoriously against the country; and the most serious consequences were apprehended from the continued drain for bullion. In the end, no doubt an efflux of bullion was sure, by rendering money and all sorts of pecuniary accommodation scarce in the metropolis, to affect the country banks as well as the Bank of England; and then the injury to industry, occasioned by the withdrawal of their accustomed accommodations from a great number of individuals, was felt in proportion to the too great liberality with which they had previously been supplied. The shock given to industrial undertakings, by the revulsion in the latter part of 1836 and in 1837, although unaccompanied by any panic, was very severe. All sorts of commercial speculations were for a while completely paralyzed, and there were but few districts in which great numbers of individuals were not thrown out of employment. Owing to the Bank of England having delayed, in 1838 and the earlier part of 1839, to take efficient measures for the reduction of its issues, despite the unmistakable evidence of their being redundant, the bullion in its coffers was reduced in September, 1839, to £2,406,000; and, but for the efficient assistance obtained from the Bank of France, its stoppage could hardly have been averted. This perilous experience having forcibly attracted the public attention to the state of the banking system, Sir Robert Peel was induced to attempt its improvement, and the measures that he introduced and carried through Parliament in 1844 and 1845 have effected most important and beneficial changes. The measures in question consisted of the Act 7 and 8 Vict. c. 32, which refers to the Bank of England and the English country banks; and the Acts 8 and 9 Vict. c. 38, 37, referring to the banks of Scotland and Ireland. These statutes were intended to obviate the chances of over-issue payable on demand, and by making the amount of such notes in circulation vary with the amount of bullion in the possession of the issuers, which object has been perfectly attained. The statutes have as completely failed to attain a second object contemplated by their author, — that of preventing great and rapid fluctuations in the rate of discount; and the truth is now recognized, that the power of over-issuing notes is one of many causes which may conduce to variations in the rate of discount, and by no means the most efficient of them. The Act of 1844 effected a complete separation between the issuing and banking departments of that establishment, giving the directors full liberty to manage the latter at discretion, while they should have no power whatever over the other.

The notes of the Bank of England in circulation for some years previously to 1844 rarely amounted to twenty, or sunk so low as sixteen millions. And such being the case, Sir Robert Peel was justified in assuming that the circulation of the bank could not, in any ordinary condition of society, or under any merely commercial vicissitudes, be reduced below fourteen millions. And the Act of 1844 allowed the bank to issue this amount upon securities, of which the £11,015,100 lent by the bank to the public was the most important item. Inasmuch, however, as the issues of the provincial banks were at the same time limited in their amount, and confined to certain existing banks, it was further provided, in the event of any of these banks ceasing to issue notes, that the Bank of England might be empowered, by order in council, to issue, upon securities, two thirds, and no more, of the notes which such banks had

been authorized to issue. Under this condition, the total secured issue of the bank has (1875) been increased from £14,000,000 to £15,000,000. But for every other note which the issue department may at any time issue over and above the maximum amount (£15,000,000) issued on securities, an equal amount of coin or bullion must be paid into its coffers. And hence, under this system, the notes of the Bank of England are rendered really and truly equivalent to gold, while their immediate conversion into that metal no longer depends, as it previously did, on the good faith, the skill, or the prudence of the directors. It is alleged that the new system is injurious by shackling the bank in the use of its credit, and the answer is, that it does this in order to prevent the greater injury of over-issues of paper. The Act prevents the bank from issuing substitutes for money which do not represent money. It does not absorb or lock up a single sixpence worth of capital, nor does it interfere in any manner of way with its employment. The gold in the issue department of the bank was not purchased by the bank, and does not belong to it. The bank is its keeper, but not its owner. It belongs to the public, or to the holders of bank-notes, who deposited it in the bank in exchange for notes, with and under the express stipulation, that on paying the latter into the bank they should receive back their gold. Any interference with these deposits would be an interference with property held in pledge for others, that is, it would be an act precisely of the same kind with that which exposes private bailees to penal servitude. But though the bank directors may not lay violent hands on the property of the public, the bank, it is obvious, has at this moment the same absolute command over its entire capital and credit, that it would have were the Act of 1844 non-existent. Apart from the practice of issuing transferable notes, the bank is free from all restraint, and is in precisely the same situation as other banking or mercantile establishments. Its directors may lend or not lend as they please, and may lay down such conditions as they please in regard to the interest and the terms of loans and discounts. In short, they may do whatever they like with their own; but further they are not permitted to go. They may not substitute shadows for realities. They cannot, whether to assist others or to relieve themselves from embarrassment, issue a single note except upon a deposit of bullion.

So far we have dealt with the legislation of 1844 in its bearing on the Bank of England. The desire of Sir Robert Peel reached beyond this, but he was unable to complete his policy. He rightly held that experience had shown that the balance of advantages lay on the side of the suppression of all note issues except that of the Bank of England, as reformed by him, or of some similar supplementary establishments regulated in the same manner. But it was obviously impossible to prohibit, without compensation, the future exercise by country bankers of the rights they had legitimately acquired; and as it was not easy to buy up the existing privileges of the private and joint-stock banks, Sir Robert Peel allowed them to remain under conditions prohibiting their extension, and he apparently hoped that country issues would gradually disappear before the rivalry of Bank of England notes. The Act of 1844, accordingly, enacted that no new bank for the issue of notes should be established in any part of the United Kingdom; and that the maximum issue of notes by the existing country banks of England should in future be limited to the average amount which they had respectively in circulation during the twelve weeks preceding April 27, 1844. It was also ordered that the names of the partners in joint-stock and other banks should be periodically published. A provision was also enacted under which an issuing bank could resign its privilege by composition with the Bank of England. The existing law was maintained preventing the issue of any notes other than the Bank of England in London, and the establishment, within sixty-five miles of London, of any branch of an English joint-stock bank having the privilege of issue.

The convertibility of the Bank of England notes has been perfectly maintained since 1844, and the management of English banks, whether private or joint-stock, has been sound and judicious, the cases of failure among them being few and contrasting strongly with the recurrent epidemics of insolvency of earlier experience.

We have already said that Sir Robert Peel contemplated an ultimate extinction of all note issues save that of the Bank of England; and he probably expected that the substitution of Bank of England notes for all others would not be long delayed. The progress actually achieved towards this end has been very slow. Out of 204 private banks in England and Wales left by the Act of 1844, with total privileged issues of £5,153,407, no more than 85 have ceased to issue; and the amount they issued which is now withdrawn was £1,285,041. Of joint-stock banks 18 have ceased to issue £342,453, out of 72 having privileged issues of £3,495,445. Only one Scotch bank has ceased to issue notes since the Scotch Act of 1845, and no alteration whatever has taken place in the fixed issues of the Irish banks.

The Bank of England transacts the whole business of government. "She acts not only," says Adam Smith, "as an ordinary bank, but as a great engine of state. She receives and pays the greater part of the annuities which are due to the creditors of the public; she circulates Exchequer bills; and she advances to the government the annual amount of the

land and malt taxes, which are frequently not paid till some years thereafter." Previous to 1786 the bank received an allowance for paying the dividends, superintending the transfer of the stock, etc., of the national debt, at the rate of £562 10s. a million on its account; but, after several successive modifications, a fresh arrangement was made in 1861 between the government and the bank, to endure for 25 years. Under this agreement the bank receives £300 per million on £600,000,000, and £150 per million on the amount of debt above that sum; but from these allowances are deducted £600,000 for exemption from stamp duties, and the whole allowance out of profit of issue, making together nearly £200,000. It should be observed that the responsibility and expense incurred by the bank, in managing the public debt, are very great. The temptation to the commission of fraud, in transferring stock from one individual to another, and in the payment of the dividends, is well known; and notwithstanding the skilfully devised system of checks adopted by the bank for preventing this, it has frequently sustained very great losses by forgery and otherwise. Formerly the business transacted at the bank was so much encumbered with forms and conditions, that the generality of merchants and ordinary people rarely thought of employing it to keep their money or make their payments. But in this respect an entire change has been effected. Checks, the minimum amount of which was formerly £10, may now be drawn of any amount, great or small; and all sorts of banking business is conducted with facility and despatch, and, it may be added, with perfect security.

The *Bank of Scotland* was established by Act of the Scotch Parliament in 1695, by the name of the Governor and Company of the Bank of Scotland. Its original capital was £100,000 sterling, distributed in shares of £83 6s. 8d. each. The Act exempted the capital of the bank from all public burdens, and gave it the exclusive privilege of banking in Scotland for twenty-one years. The objects for which the bank was instituted, and its mode of management, were intended to be, and have been, in most respects, similar to those of the Bank of England. The responsibility of the shareholders is limited to the amount of their shares. The capital of the bank was increased to £200,000 in 1774, and was enlarged by subsequent acts of Parliament, the last of which was passed in 1804, to £1,500,000, its present amount. Of this sum £1,000,000 has been paid up. On the union of the two kingdoms in 1707, the Bank of Scotland undertook the recoinage, and effected the exchange of the currency in Scotland. It was also the organ of government in the issue of the new silver coinage in 1817. The Bank of Scotland is the only Scotch bank constituted by Act of Parliament. It began to establish branches in 1696, and issued notes for one pound as early as 1704. The bank also began, at a very early period, to receive deposits on interest, and to grant credit on cash accounts, a minute of the directors with respect to the mode of keeping the latter being dated as far back as 1729. It is, therefore, entitled to the credit of having introduced and set on foot the distinctive principles of the Scotch banking system, which, whatever may be its defects, is perhaps superior to most other systems hitherto established. Generally speaking, the Bank of Scotland has been cautiously and skilfully conducted; and there can be no doubt that it has been productive, both directly and as an example to other banking establishments, of much public utility and advantage.

The *Royal Bank of Scotland* was established in 1727. Its original capital of £151,000 has been increased to £2,000,000. — The *British Linen Company* was incorporated in 1746, for the purpose, as its name implies, of undertaking the manufacture of linen. But the views in which it originated were speedily abandoned, and it became a banking company only. Its capital amounts to £1,000,000. — None of the other banking companies established in Scotland are chartered associations with limited responsibility, the partners being liable, to the whole extent of their fortunes, for the debts of the firms. The number of partners is in every case considerable. The affairs of the banks are uniformly conducted by a board of directors, annually chosen by the shareholders.

The *Bank of Ireland* was organized in 1783, with similar privileges to those of the Bank of England in respect to the restriction of more than six partners in a bank, and the injury that Ireland has sustained from the repeated failure of banks may be mainly attributed to this defective regulation. Had the trade of banking been left as free in Ireland as in Scotland, the want of paper money that would have arisen with the progress of trade would in all probability have been supplied by joint-stock companies, supported with large capitals and governed by wise and effectual rules.

In 1797, when the Bank of England suspended its payments, the same privilege was extended to Ireland; and after this period the issues of the Bank of Ireland were rapidly increased. In 1797 the amount of the notes of the Bank of Ireland in circulation was £621,917; in 1810, £2,266,471; and in 1814, £2,986,950. In 1821, in consequence of eleven banks having failed nearly at the same time, in the preceding year, in the South of Ireland, government succeeded in making an arrangement with the Bank of Ireland, by which joint-stock companies were allowed to be established at a distance of fifty miles (Irish) from Dublin, and the bank was permitted to increase its capital from 2½ to 3 millions sterling. The bank has of late established branches

In all the principal towns of Ireland. The three principal banks of Ireland are: the *National Bank of Ireland*, which has a head office, with several branches, in London; the *Provincial Bank of Ireland*, which has also set up a head office in London, without, however, competing for general business in the metrop-

olis; and the *Munster Bank*, which has its head office in Cork, and has established upwards of 40 branches.

The following table gives the financial condition of all the joint-stock banks of England, Scotland, and Ireland, on January 1, 1879:—

NAME OF BANK.	When estab- lished.	Capital author- ized.	Shares of.	Paid-up capital	Paid per share	Reserve.	Dividend for the complete year 1878.	Price, Jan. 1, 1879.

## XI. PRINCIPAL SEAPORTS.

**Aberdeen.** the chief seaport in the N. of Scotland, and the fifth Scottish town in population, industry, and wealth. It lies in lat. 57° 9' N., lon. 2° 6' W., on the German Ocean, near the mouth of the River Dee, and is 542 m. N. of London, and 111 m. N. of Edinburgh, by rail. A defective harbor, and a shallow sand and gravel bar at its entrance, long retarded the trade of A., but they have been greatly deepened, and a new breakwater against S. and S. E. storms has been recently built. Aberdeen Bay affords safe anchorage with off-shore winds, but not with those of the N. E. On the Girdleness, the S. point of the bay, in lat. 57° 8' N., lon. 2° 3' W., there is a lighthouse with two fixed lights, one vertically below the other, and respectively 115 and 185 feet above mean tide. Aberdeen has extensive manufactures of woollens, linen, cotton, chemical works, iron foundries, etc. This port has been long famed for ship-building, especially for its fast clippers. About 250 vessels, with an aggregate of 110,000 tons, belong to the port. They trade with British ports, the Baltic and Mediterranean ports, and many more distant regions. In 1878, 462,616 tons of shipping arrived at the port. The export trade, exclusive of coasting, is insignificant. Pop. 88,125.

**Barrow-in-Furness,** a borough and port in the hundred of Lonsdale, Northwest Lancashire, England, on the Irish Sea, opposite the island of Walney, at the extreme point of the peninsula of Furness, which lies between Morecombe Bay and the estuary of the Duddon. It is a thriving and flourishing town, which, from 325 inhabitants in 1847, has risen to 40,000 in 1880. In the vicinity are veins of pure hematite iron, which are extensively worked. The principal industry is the manufacture of iron and jute, and iron-ship building. A branch of the Walney Channel is now converted into docks, which serve as a harbor, and the beach as a quay. In 1878, 1,689 vessels entered the port, with a tonnage of 374,600 tons.

**Belfast,** the chief manufacturing and commercial town of Ireland, and the capital of Ulster. It is situated in lat. 54° 38' 8.5" N., lon. 5° 55' 53.7" W., at the mouth of the Lagan, which flows into Belfast Lough (Carrickfergus Bay), and is built on an alluvial deposit and land reclaimed from the sea; the greater portion of which is not more than six feet above high-water mark. The outer harbor is one of the safest in Ireland, and ships of large draught can now be brought to the quays, which extend for about a mile on both sides of the river. There are also seven extensive docks and tidal basins, supplied with the necessary conveniences for the shipping. In 1878, 15,877 vessels, whose aggregate tonnage was 1,504,625, entered the port. The exports from Belfast being largely conveyed by steamer to London, Liverpool, and Glasgow, and thence transhipped to their destination, do not appear in the Board of Trade returns, but it may be safely estimated that the gross value of the exports exceeds \$100,000,000 annually. The most extensive manufactures of Belfast are those of flax. Pop. 200,000.

**Berwick-upon-Tweed,** a seaport town of Scotland, at the mouth of the Tweed, in lat. 55° 48' N., lon. 1° 59' W., 300 m. N. by W. of London, and 47 E. S. E. from Edinburgh. The depth of water at the bar is 17 feet at ordinary tides, 22 feet at spring tides, but the channel is narrow. Berwick is famous for its salmon fisheries. Pop. 8,721.

**Bridgewater,** a seaport town of Somersetshire, on both sides of the river Parret, 29 m. S. S. W. of Bristol. The river, which is subject to a bore often two fathoms deep at the

mouth, is navigable for vessels of 700 tons up to the town. Pop. 10,259.

**Bristol**, a free port town in the W. of England, situated in lon.  $2^{\circ} 35' 28''$  W., lat.  $51^{\circ} 27' 6''$  N., 118 m. from London by rail, and 8 m. inland from Bristol Channel, with which the port communicates by the Avon. The creation of Bristol a free port in 1848 has resulted in great increase of trade. The tonnage of foreign vessels with cargoes entering the town in 1878 was 475,663. Bristol stands fourth of all the seaport English towns in the amount of customs revenue received. It was the first English port that established regular steam communication with the U. States, the first voyage having been made by the "Great Western" in 1838. Its most important manufactures are those of shoes and cotton. Pop. 202,950.

**Cardiff**, a seaport town of England, in S. Wales, county Glamorgan, on the Bristol Channel, 25 m. W. of Bristol, and 170 W. of London. It possesses magnificent docks, whence coal and iron are yearly exported to the quantity of 1,500,000 tons. It is almost exclusively a mineral port. Pop. 36,249.

**Chatham**, a naval arsenal and seaport of England, county Kent, on the Medway, 28 m. E. S. E. of London. The dockyard, including the arsenal, is about 1 m. in length, and is strongly fortified. Chatham is almost wholly dependent on the great military and naval establishments of the surrounding neighborhood.

**Chester**, a city and seaport of England, capital of Cheshire, on the Dee, 17 m. S. by E. of Liverpool. This port is almost entirely engaged in the coasting trade. Pop. 35,701.

**Culchester**, a seaport town of England, county Essex, 50 m. N. E. of London. It is almost entirely engaged in the coasting trade. Pop. 23,337.

**Cork**, a city and port of Ireland, and a county in itself, 138 m. S. W. of Dublin, in lat.  $51^{\circ} 53' 39.3''$  N., lon.  $8^{\circ} 20' 20''$  W. The city proper is built on an island formed by the Lee, 11 m. above the entrance of that river in Cork Harbor. Until lately it ranked as the second city of Ireland, but of late Belfast has far surpassed it in population, wealth, and commerce. Its trade, however, is extensive, the exports consisting of butter, corn, flour, and other Irish produce. The registered tonnage of vessels at the port in 1878 was 35,016. The number and tonnage of vessels entering the port, employed in the coasting trade, reached 2,653 vessels and 678,511 tons; in the British colonial trade, 64 vessels and 27,914 tons; in the foreign trade, 617 vessels, tonnage 137,560. Pop. 78,642. *Cork Harbor* is a fine land-locked basin, formed by the estuary of the Lee, which is navigable to  $\frac{1}{2}$  m. above Cork city. It is large and deep enough to contain the whole British navy, and has an entrance one mile across, within which its breadth varies to 8 m. It contains Spike and Haulbowline Islands, on which are artillery barracks and various ordnance works. Lat.  $51^{\circ} 50' 4''$  N., lon.  $8^{\circ} 19' 19''$  W. On its shores are the towns of Cove and Passage, with quays 4 m. in length, and which were erected at a cost of \$500,000.

**Dover**, the principal cinque-port of England, on Dover Strait, 72 m. E. S. E. of London, at the nearest point of England to the continent of Europe, being 21 m. from Cape Grisez, and 25½ m. N. W. of Calais. Its principal feature is its castle, perched on a cliff about 320 feet above sea-level, which, with its immense defences, renders it one of the strongest, as it is certainly one of the most important, fortresses in the British Islands. Pop. 28,270.

**Dublin**, the metropolis of Ireland, in prov. Leinster, and a county in itself. It stands on both sides of the river Liffey for the space of 2 m., before it falls into the splendid Bay of Dublin. It is situated in lat.  $53^{\circ} 20' 33''$  N., lon.  $6^{\circ} 17' 13''$  W., 138 m. W. from Liverpool, and 60 m. W. of Holyhead. Dublin has little of the bustle which should mark so large a city. There is, too, a spirit of foolish pride which seeks to disown trade; and the tendency to be poor and genteel in the civil service, at the bar, in the army, in professional life, rather than prosperous in business, is one of the most unfortunate and strongly marked characteristics of Dublin. That this is attributable to the lingering yet potent influence of an unhappy past is held by some; while others attribute the weakness to the viceregal office and the effects of a sham court. Dublin produces nothing for exportation save whiskey and porter. The whiskey-trade has been greatly extended. Of the 22 distillers and 43 rectifiers in Ireland, the principal are in Dublin; the three houses of Jameson and Roe and Power may be especially mentioned. The porter-trade is also very large. The exports in 1875 were 361,465 hogsheads. The docks in the river have been improved considerably within the last quarter of a century. The river has been deepened, wharves have been built, new docks have been constructed; and a basin now almost completed, at a cost of \$1,380,000, will add greatly to the accommodation. The two great lines of railway, the Midland and the Great Southern, have extended their ways to the river's edge, so that traffic is much easier and swifter between the provinces and the boats for England than in former times. In 1873, 621 British and foreign vessels entered, and 465 cleared the port of Dublin; while 7,548 vessels engaged in the coasting trade entered. The total value of all exported articles from Dublin in 1878 was \$255,500. Pop. 314,968.

**Dundee**, a seaport town on the E. coast of Scotland, in the county of Forfar, on the N. bank of the Firth of Tay, 12 m.

from the confluence of that estuary with the German Ocean. It is the third town in Scotland as regards population, and the second in commercial importance. Its lat. is  $56^{\circ} 27' 27''$  N., its lon.  $2^{\circ} 58' 10''$  W.; it is distant from Edinburgh 42 m. N. N. E., from Perth 22 m. E. It extends nearly 3 m. along the shores of the Tay, and varies in breadth from half a mile to a mile; and the ground gradually rises towards the hill of Balgay and Dundee Law, the summit of the latter being 535 feet above the sea-level. Its general appearance is pleasing and picturesque, and the surrounding scenery very beautiful. Dundee is the chief seat of the linen manufacture in Britain, and from a very early time appears to have had a special reputation in this branch of industry. Side by side with the extension of the linen-trade has been that of jute spinning and weaving. Large cargoes of this material are imported into Dundee direct from India, and it is manipulated on an enormous scale. In fact, the manufacture of flax, hemp, and jute fabrics constitutes the staple trade of the town, and supports, directly or indirectly, the great bulk of the inhabitants. There are upwards of 70 steam spinning-mills and power-loom factories, employing above 50,000 persons. Some of these buildings are of great size and considerable architectural elegance, those of Messrs. Baxter, Messrs. Cox, and Messrs. Gilroy being especially conspicuous. These three afford employment to above 12,000 hands. The principal textile productions are osenaburgs, dowlas, canvas, sheetings, bagging, jute carpeting, etc.; and the total value of these fabrics annually produced has been estimated at upwards of \$35,000,000. Among the other industries of Dundee may be mentioned ship-building, engineering, tanning, and leather manufactures (including shoemaking by machinery), all of which are conducted on a large scale. There are also considerable foundries, breweries, corn and flour mills, and confectionery and fruit-preserving works. — Messrs. Keiller & Son's "Dundee marmalade" having a most extensive reputation. The prosperity of Dundee is in a large measure due to its commodious harbor and its magnificent docks. The harbor works extend about 2 miles along the river-side, and the docks, five in number, cover an area of 35 acres. Although they cannot compare in extent with those of London or Liverpool, they are probably unsurpassed in G. B. for stability and convenience. There were built in Dundee, in 1878, 29 vessels, with a tonnage of 17,413, and at the beginning of 1880 the shipping belonging to the port consisted of 216 vessels, tonnage 87,781. Pop. 145,000.

**Falmouth**, on the S. W. coast of England, in county Cornwall, on the S. side of Falmouth Harbor, 15 m. N. N. E. of Lizard Point, and 267 m. W. S. W. of London. It is here noticed in consequence of the excellence of its harbor, and its proximity to Land's End. For about 150 years it was the port from which the mail packets for the Mediterranean, Spain, the West Indies, and South America were despatched; and though these steamers now start from other ports, it maintains steam communication with London, Liverpool, Dublin, Penzance, Plymouth, and Southampton. The harbor is one of the best refuges for shipping in England. Its entrance between St. Anthony's Head on the E. and Pendennis Castle on the W. is about a mile in width, and it thence stretches inland about  $\frac{5}{8}$  m. It has depth of water and excellent anchorage for the largest ships, and vessels of considerable burden can discharge their cargoes at the quay. In 1876 the number that entered the port was 803, with a tonnage of 113,617; the number that cleared was 334, tonnage 26,522. The total value of imports was \$1,202,370, and of exports \$26,305. Pop. 5,294.

**Folkestone**, or **Folkestone**, a fortified seaport-town of England, county Kent, in hundred of same name, 62 m. S. E. by E. of London, and 7 W. by S. of Dover. It possesses a spacious harbor and noble pier (erected at a cost of \$250,000), whence the tidal steamers sail twice a day to Boulogne on the French coast. Pop. 10,641.

**Galway**, a seaport town of Ireland, at the N. E. extremity of a bay of same name, 113 m. W. of Dublin. The harbor is safe and commodious, having been much improved of late years. It was used for a time as a station for the large mail-steamer which a few years ago ran from Galway to New York. Its foreign trade is unimportant. Pop. 23,937.

**Glasgow**, a great commercial and manufacturing city of Lanarkshire, Scotland, situated on the River Clyde, in lat.  $55^{\circ} 51' 32''$  N., lon.  $4^{\circ} 17' 54''$  W., 42 m. E. by S. of Edinburgh. The *Clyde* is one of the principal rivers in Scotland, and has its rise among the mountains that separate the counties of Dumfries and Lanark. The length of this stream, from its source to its junction with the Western sea, is about 100 m. Along its whole course it is beautified by magnificent natural scenery and embellishments of art. Its banks are crowded with the abodes of industry and a thriving population. The site of Glasgow occupies both sides of the river, and though at a distance of above 30 m. from the influx into the sea, the tide, which flows a considerable way above the town, gives it a command of trade and means of ready conveyance for commercial purposes to every quarter of the world. As a guide to mariners, it may be mentioned that vessels of 19 feet draught of water can arrive at the harbor of Glasgow, and that vessels drawing 15 to 16 feet may always arrive and depart without touching the bottom. At the entrance to the river vessels are placed

under the charge of pilots, who are well acquainted with the channel, which is well marked with beacons and buoys. It may be considered that the river is deepening at the rate of one foot in every five years. A ship on reaching the mouth of the river had best commence ascending at half-tide. There are no particular usages connected with the harbor of Glasgow beyond those adopted on most other rivers and harbors. Lights are permitted in the harbor from 6 A. M. to 10 P. M. — Glasgow may be said to be *cosmopolitan* in her commerce and manufactures, uniting within herself the businesses and trades of almost every other town and city in the United Kingdom. It hence follows that while one branch of manufacture or trade may be dull, another may be prosperous, and accordingly Glasgow does not feel any of those depressions which so frequently occur in places which have only one or two branches of manufacture or commerce. The great industrial occupations of Glasgow are its cotton spinning and weaving; its collieries and iron manufactures; its iron-ship building and machine making, and its chemical manufactures. Pop. 555,933.

**Gloucester**, a fine city, capital of county of same name, on the left bank of the Severn, 33 m. N. N. E. of Bristol. It has spacious docks, and communicates with the open port of the Severn by means of a ship-canal 17 m. in length. Pop. 18,486.

**Greenock**, a manufacturing town and seaport of Renfrewshire, Scotland, on the S. bank of the Frith of Clyde, 22 m. below Glasgow, in lat  $55^{\circ} 57' 3''$  N., lon.  $4^{\circ} 45' 30''$  W. In

**Inverness**, a seaport town of Scotland, situated on both sides of the river Ness, at its entrance into the Moray Frith, 115 m. from Edinburgh, in lat  $57^{\circ} 28' 36''$  N., lon.  $4^{\circ} 13' 30''$  W. It is a fine town, with a commodious harbor, and was long considered as the metropolis of the highlands. Pop. 14,425.

**Leith**, a seaport town of Scotland, on the Frith of Forth, at the mouth of the river Leith, in lat.  $55^{\circ} 58' 9''$  N., lon.  $3^{\circ} 10' 5''$  W. Leith may be considered the seaport of Edinburgh, from which it is only about 2 m. distant. It has several docks of great magnitude, in which vessels of upwards of 2,000 tons burden, of 320 feet in length, and 58 feet in breadth, can be accommodated. Besides having regular steam communication with Rotterdam, Hamburg, Hull, London, Newcastle, and the North of Scotland, Leith trades largely with the Baltic, Mediterranean, North America, and Australia. The exports are principally coal, iron, spirits, ale, paper, linen, yarn, etc. The chief manufactures of Leith are ropes, sailcloth, locomotive engines and machinery, glass, soap, ale, refined sugar, and oil-seed cakes. Iron and timber ship building is also carried on to a considerable extent. Pop. 35,000.

**Liverpool**, a seaport of England, and the third town in population of the United Kingdom. It is situated in Lancaster County, on the Mersey, about 4 m. from the Irish Sea, 32 m. W. by S. of Manchester, 202 m. N. N. W. of London by railway; lat.  $53^{\circ} 24' 48''$  N., lon.  $3^{\circ} 0' 1''$  W. It has a length of about 8 miles, and a breadth of about  $\frac{3}{4}$  at its widest points. L. stretches along the river, and has docks and basins having

Fig. 248. — LIZARD POINT.

front of the town there is a fine and splendid bay, along the shore of which the town stretches for about 3 m. Greenock is largely engaged in iron-ship building, and carries on an extensive foreign trade. Pop. 57,146.

**Hull**, one of the principal commercial towns and seaports of England, in Yorkshire, 150 m. N. of London, at the confluence of the Hull and Humber Rivers. Vessels of the largest size can come up to the town; while the Hull, Ouse, and Trent, affluents of the Humber, with their tributary streams and canals, afford facilities for trade with a large extent of country. It is also connected by railways with all parts of the kingdom. These advantages have been improved by the activity of the inhabitants, so that Hull ranks as the third port in the kingdom, the value of its exports being inferior only to those from Liverpool and London. Hull has magnificent docks, and the quays around them are spacious. Steamers sail regularly to and from London, Leith, Aberdeen, Newcastle, Yarmouth, Hamburg, Rotterdam, Copenhagen, Antwerp, etc. Hull is the principal entrepôt of the Baltic timber-trade on the E. coast of Britain. The staple imports are timber, deals, grain, and seeds, sheep's wool, tallow, hemp, flax, hides, iron bars, green fruit, bones, madder, bark, turpentine, cattle, sugar, etc. The chief articles of export are cotton stuffs and twist, woollen goods and woollen yarn; iron and hardware; linens and linen yarn; earthenware, etc. The industrial establishments of Hull are chiefly connected with the building and equipment of ships, comprising ship-building yards, rope-walks, and manufactures of canvas, chains, chain cables, and steam machinery. Pop. 140,002.

an aggregate water-area of nearly 200 acres, and extending for 9 m., erected at a cost of \$65,000,000. Among the largest of the docks are the Brunswick, Albert, Waterloo, Prince's, Clarence, Nelson, Victoria, Trafalgar, Collingwood, Wellington, Stanley, Huskisson, Sandon, Salisbury, Canada, etc. The streets are mostly spacious, and airy, and some of them elegant. The older parts of the town have been greatly improved, while the public buildings are formed in a style of elegance and splendor suitable to the taste and opulence of its inhabitants. The trade of Liverpool with all parts of the world is very great. Its commercial intercourse with the U. States is particularly of great magnitude, for the great trade of Liverpool is cotton, the largest quantities of which come from our Southern States. It receives, also, from this country considerable quantities of wheat, corn, and flour. An immense emigration takes place yearly from this port. Liverpool has several large fleets of splendid steamers in almost daily communication with New York, Boston, Philadelphia, and Baltimore. In 1878 the total shipping of Liverpool was 12,788,516 tons. There are several eminent ship-builders in Liverpool, but the greater part of the trade is now in repairing and in the building of iron ships. There are five building-yards on the Lancashire side of the river, and three on the other side. Those on the Cheshire side combine graving with building docks, and, although there are several graving-docks on the Liverpool side, they are found to be inadequate to the wants of the port. As might be expected, a large trade is carried on in ships. About 700 ships are sold yearly, of which about a fifth is bought by foreigners. Liverpool is a place of trade rather than of manu-

factures, and those manufactures which exist are more for the supply of local wants than for general purposes. Pop 527,083.

**London** [Fr. *Londres*], the metropolis of the British Empire, and the principal shipping-port of *G. B.*, is the most populous, wealthy, and commercial city of the world. It is situated partly and principally on the N. bank of the Thames, in the county of Middlesex, and partly on its S. bank in the county of Surrey, about 45 m. above the river's mouth at the Nore, and 15 below the highest tide-way. St. Paul's, the most striking object in the city, is in lat.  $51^{\circ} 30' 48''$  N., lon.  $0^{\circ} 5' 48''$  W. of Greenwich. The site on the N. side is high and dry, but on the S. it is so low as to be under the level of the highest tides, though by a well-constructed system of drainage it is kept perfectly free from wet. The air is temperate, and rather dry than moist, and the health of the inhabitants has gradually improved from the earlier part of the last century, when the deaths were annually 1 in 20 of the population, whereas at present they are about 1 in 40. Exclusive of the city of London (properly so called) the metropolis comprises the city and liberties of Westminster, the parliamentary boroughs of Tower Hamlets, Finsbury, Hackney, Marylebone, Southwark, Lambeth, Kensington, Chelsea, and Greenwich, and other contiguous districts, which, though formerly distinct, are now combined to form the huge agglomeration of streets and houses called LONDON. Its length E. from Plumstead in Essex to its W. boundary, Hammersmith, in Middlesex, on the N. bank of the Thames, may be estimated at 19 m.; its breadth N. to S., or from Hainpstead, in Middlesex, to Camberwell, county Surrey, at 14 m.; while its circumference is not less than 40 m. The united area of the city proper, Westminster city and liberties, etc. (excluding the divisions of Greenwich, Chelsea, and Kensington), is 31,493 acres. The N. and S. portions of London are connected by bridges, viz., those of London Southwark, Blackfriars, Waterloo, Hungerford, Westminster, Vauxhall, Chelsea, Wandsworth, Putney, and Hammersmith, besides several railway bridges. Communication is also maintained subterraneously by the Thames Tunnel and subway. The capital of a great empire, with immense wealth concentrated in it, having easy access, both by land and water, to all parts of the kingdom, and every facility of communication with foreign countries, London has become the greatest commercial city in the world. Its commercial growth and prosperity are especially to be ascribed to its great river-port, the *Thames*. This famous stream has its source within the borders of Gloucestershire, a little to the southwest of Cirencester, and becomes navigable at Lechlade, 138 miles above London. It is first affected by the tide about 15 miles above the metropolis, but before reaching this point it is swollen by junction with the Isis, Kennet, Coln, and Wey. The city corporation are the chief conservators of the river, and appoint a navigation committee, who superintend the towing-paths, bridges, water-courses, and whatever relates to the river, as far as a stone a little above Staines Bridge. Higher up the supervision is divided between the city and a body chiefly composed of the landowners on both sides of the river. The conservation of the river below London is also in some measure under the government of the city corporation, but the Trinity House has concurrent jurisdiction, and no ballast can be raised without its authority. The appointment and control of pilots, the placing and repairs of landmarks and buoys to indicate the channels, and the establishment of floating lights, are also under the superintendence of the Trinity House. Close to London Bridge there is water sufficient for vessels of 800 tons burden, and the legislature has placed the shipping of the port, and their moorings, under the direction of the harbor-masters, nominated by the corporation, and approved by the Trinity House. The shoalness, currents, and shoals in the river, and its varying depth, render the navigation rather intricate. The river pilots, who are a distinct class, conduct vessels to Gravesend, where they are relieved by the sea-pilots. The city proper, forming the E. central division of London, may be termed the centre of commerce of the British Empire. What is legally termed the port of London extends about 7 m. below London Bridge beyond Blackwall; though the actual port, consisting of the upper, middle, and lower pools, does not reach beyond Limehouse. Independent of the river accommodation thus afforded for shipping, a series of vast inland docks extends from the Tower to nearly opposite Greenwich. The *West India Docks*, the largest of these (opened in 1802), comprise about 295 acres, a fourth part of which is water-area, the rest being occupied with quays and warehouses of great magnitude. There is, also, here an export and import dock, with ample room for 500 large merchantmen. The *London Docks*, about  $\frac{1}{2}$  m. below London Bridge, cover about 100 acres of ground, of which nearly a third part is water. The vaults beneath the warehouses have cellars for 65,000 pipes of wine, and one of them has an area of 7 acres. The tobacco warehouses are also very extensive. The *E. and W. India Docks*, smaller than the before-mentioned, and situated further down the river, have a depth of 23 feet, with a water-area of 30 acres. The *Commercial Docks*, on the S. side of the river, contain a water-surface of 40 acres; and the *St. Katharine's Docks*, just below the Tower, enclose 24 acres, all

being surrounded by extensive warehouses. London, when compared with some of the towns in the N. and W. of England, can scarcely be called a manufacturing place; yet the various articles produced here employ many thousand persons. The silk manufacture, especially, employs a large number of hands. The manufacture of London porter and beer is a much more lucrative business, but a London brewery requires a very large capital. Sugar-refining and clock and watch making also prevail to a considerable extent, the latter chiefly in a district called Clerkenwell. London-built carriages are generally considered the best, as they are undoubtedly the most elegant, in the world. London enjoys a high reputation for the manufacture of numerous smaller articles, such as mathematical, surgical, and musical instruments, jewelry of superior kinds, gold and silver plate, etc. The shops in London are, generally speaking, well managed, and many of them are hand-somely fitted up, especially those in Bond Street, Regent Street, and Oxford Street. The wholesale shops or warehouses are chiefly to be found in the city; the retail shops, particularly those on a large scale, being more general in the west or fashionable end of the metropolis. The *Royal Exchange*, colossal in proportions, and occupying a commanding position between the Bank of England and Cornhill, is a spot where great mercantile transactions are daily concluded. The building is quadrangular, and the interior surrounded by arcades. In the centre, which is uncovered and unprotected from the weather, stands a statue of her Majesty, by Lough. The outside of the building, except the grand western entrance, is occupied by small shops; and on the upper floor is Lloyd's, where the business of marine insurance is conducted by underwriters. Merchants and brokers resort much to coffee-houses in the vicinity of the Exchange for the transaction of business. Most of the larger transactions are negotiated by brokers, who in general confine themselves to one branch of trade, with which they are thoroughly acquainted. Near the Royal Exchange and the Bank is the Stock Exchange, where real and fictitious sales are made of property in the public funds, etc. In 1878 the total shipping of the port of London was 14,332,653 tons. Pop. 3,533,484.

**Londonderry**, a seaport town of Ireland, situated on the Foyle, 120 m. from Dublin, in lat.  $54^{\circ} 59' 6''$  N., lon.  $7^{\circ} 19' 19''$  W. It has an extensive trade with the West Indies and the U. States. The harbor is deep, wide, and tolerably secure. Pop. 20,875.

**Milford-Haven**, a harbor of England, on a basin or deep inlet of the Atlantic, on the coast of South Wales, county Pembroke, forming one of the best ports in the British dominions. Latitude of St. Anne's Heads, the N. W. extremity of the entrance, and on which are three lighthouses, with fixed lights,  $51^{\circ} 41' 1''$  N., lon.  $0^{\circ} 10' 25''$  W. Length of haven, about 15 m.; average breadth, 2 m. It is completely land-locked, has deep water, and the whole shipping of the Empire might ride here as safely as in dock, in any weather; while the access is easy, and the egress can be accomplished, by aid of the strong ebb, even in head-winds.

**Montrose**, a seaport town of Scotland, county of Forfar, at the mouth of the S. Esk, on a projecting tongue of land, between the German Ocean on the E. and the basin of Montrose on the W., 60 m. N. N. E. of Edinburgh; lat.  $56^{\circ} 42' 5''$  N., lon.  $2^{\circ} 28' 1''$  W. The harbor is one of the best on the E. coast of Scotland. Pop. 15,000.

**Newcastle-upon-Tyne**, a town and river port of England, capital of county Northumberland, on the Tyne, 54 m. E. of Carlisle. Its importance is mainly owing to the coal-trade from the mines along both banks of the Tyne. 5,168,330 tons of shipping cleared the port in 1868, mainly consisting of coal. Pop. 120,000.

**Plymouth**, a seaport town and naval station of England, and, on account of its harbor and docks, one of the most important maritime places of *G. B.*, situated on the E. side of a peninsula between the rivers Plym and Tamar, at the head of Plymouth Sound. lat.  $50^{\circ} 22' 1''$  N., lon.  $4^{\circ} 10' 24''$  W. The port of Plymouth is distinguished for its capacity and security; it is capable of containing 2,000 sail, and is one of the best harbors in the world. It consists of three divisions: Sutton-port, adjoining the town; Catwater, formed by an estuary of the Plym; and the Bay of Hamoaze. At the mouth of these harbors the great bay of Plymouth Sound forms an excellent roadstead, which is now completely secure by the erection of the breakwater across the entrance. This is an isolated mole at the entrance of the Sound 5,100 feet long, and opposing a barrier to the heavy swell of the Atlantic. The Sound is 3 m. long and  $\frac{1}{2}$  m. wide, and forms the harbor of Davenport and Plymouth. Altogether there are 9 docks, and the one last formed is said to be the largest in Europe. It is a stopping-place for the steamers between Hamburg and New York. Pop. 70,000.

**Portsmouth**, a seaport and the principal naval station of England, in the English Channel, on the W. side of the island of Portsea, at the mouth of the bay called Portsmouth Harbor, lat.  $50^{\circ} 47' 1''$  N., lon.  $1^{\circ} 8' 1''$  W. Portsmouth Harbor excels every other in *G. B.* in depth, capaciousness, and security. At its entrance the harbor is very narrow, but soon expands into a great width. Everywhere the anchorage is good, the depth sufficient for ships of any size, and in extent almost sufficient

to contain the whole English navy. The roadstead of Spithead, between Portsmouth and the Isle of Wight, can contain 1,000 sail with security. The dock-yard, the great naval arsenal of England, extends along the W. shore of the harbor, and includes an area of 293 acres. Ship-building and other manufactures are carried on to a considerable extent. The coal and other fisheries are actively prosecuted, and Portsmouth has considerable foreign and coasting trade. Pop. 120,000.

**Preston**, a town and riverport of England, county Lancaster, on the Ribbles, about 15 m. from its confluence with the Irish Sea, 23 m. N. E. of Liverpool. Its manufactures and exports consist principally of linen and cotton goods. About 140 vessels (tonnage, 8,500) belong to this port. Pop. 90,000.

**Scarborough**, a seaport town of England, county York, on a bay in the German Ocean, 227 m. N. of New York. Its harbor is extensive, safe, and of easy access. Pop. 15,000.

**Shields (South)**, a seaport town of England, county Durham, at the mouth of the Tyne, 8 m. N. E. of Newcastle. Pop. 35,000.

**Southampton**, a seaport town of England, and a county by itself, in the S. part of the county Hants, occupying a peninsula between the mouths of the Test and Itchen rivers, at the head of Southampton water, 12 m. S. S. W. from Winchester, on the Southwestern Railroad, 72 m. S. W. from London, in lat. 50° 54' N., lon. 1° 24' 2" W. The docks on the E. of the town have an area of 208 acres, and admit steamers of more than 700 tons burden. The West India, Chinese, Australian, and Mediterranean mails have their station here, and the town communicates by steamers with all the ports of South England, the Channel Islands, Ireland, and by railroad with London, and all the centre of England. The port extends from near Portsmouth to Christchurch. Here are some manufactures of silks

and carpets, but ship-building and general commerce are the chief sources of wealth. Southampton is a stopping-place for the steamers between Bremen and New York. In 1878, 992,447 tons of shipping entered, and 705,517 cleared, the port. Pop. 55,000.

**Stockton-on-Tees**, a seaport town of England, county Durham, 11 m. E. N. E. of Darlington, on the left bank of the Tees. Ship-building, chiefly in iron, is carried on to a great extent. The principal article of export is coal. Pop. 32,000.

**Sunderland**, a seaport town of England, county Durham, on the Wear, 13 m. N. E. of Durham. Iron-ship building is extensively carried on. Sunderland possesses, next to Newcastle, the largest export trade of coal in the kingdom. Pop. 100,000.

**Waterford**, a city and seaport of Ireland in province Munster, on the river Suir, which joins the Barrow, and forms a bay called Waterford Harbor, 62 m. N. E. of Cork. The harbor is deep and spacious, and has a fixed light on Hook Tower, 139 feet above the sea. Pop. 25,000.

**Whitehaven**, a seaport town of England, county Cumberland, on the Irish Sea, and near the Solway Frith, 35 m. S. W. of Carlisle. It has extensive iron and brass foundries. Pop. 22,000.

**Yarmouth, or Great Yarmouth**, a seaport town of England, county Norfolk, lat. 52° 36' 8" N., lon. 1° 43' 7" E. It stands on a peninsula, having the sea on the E., and on the W. the Yare, over which there is a drawbridge, which affords communication with South Town, or Little Yarmouth, and with Gorleston. Its harbor is perfectly secure, but the coast upon which it is built is the most dangerous in England, and has been often the scene of the most disastrous shipwrecks. It is the principal seat of the English herring-fishery, and has also a considerable coal-trade. Pop. 45,000.

**Great Hundred**, the long hundred of six score. See HUNDRED.

**Great Western**, a Marine insurance Co., located in New York City, organized in 1855. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$662,080; net surplus, \$94,273.76; risks in force, marine and inland, \$4,111,052; premiums, \$50,057.23; premiums received since the organization of the Co., \$34,788,480; losses paid, \$24,142,942.64; cash dividends paid to stockholders, \$2,800,498.

**Greaves**, the sediment of melted tallow made into cakes, and used in England for feeding dogs and cattle.

**Grebe**, an aquatic bird, *Podiceps cristata*. Its feathers, which are of a rich silver-white color, variously shaded with brown, are retained on the skin, and worn as trimmings, or made into muffs, cuffs, etc. They are very durable.

**Greece**, a kingdom in the S. W. extremity of Europe, lying between lat. 36° 16' and 39° 34' N., and lon. 20° 43' and 26° 28' E. In its flourishing period *G.* comprised the entire S. portion of the E. peninsula of Europe, extending N. to lat. 42°, including Thessaly and a part of modern Albania, with the Ionian Islands, Crete, and the islands of the Archipelago. This famous region was originally called *Hellas*, and received the name of Greece from Græcus, Prince of Thessaly. The modern kingdom of *G.*, though much smaller than the ancient country of the same name, comprises the territories of the most celebrated and interesting of the ancient states of *G.*, including all that portion of the continent S. of the gulfs of Arta and Volo, together with the islands of Eubœa, the Cyclades, and the two Sporades. Continental *G.* is naturally divided by the isthmus of Corinth into

two portions: the northern, or Hellas; and the southern, comprising the Peloponnesus, or Morea. The kingdom is divided into 13 Nomos, or Nomarchies, and subdivided into 59 Eparchies. By the

at the time to 16,414,207 drachmas, or \$2,931,105, being more than one half of the total revenue of *G.* At the liberation of the country in 1830 there were only 9 towns which had partly escaped the

The government is a constitutional monarchy. The present constitution of *G.*, elaborated by a constituent assembly, and adopted Oct. 29, 1864, vests the whole legislative power in a single chamber of representatives, called the Boulé, elected by manhood suffrage for the term of 4 years. The executive is vested in the king and his responsible ministers. The number of public functionaries in *G.* is extraordinarily large. In 1880 there were 18,860 officials in the government service; and, "supposing these 18,860 persons to have families amounting in the average to 5 persons, we find that they maintain 94,300 souls, or one twelfth of the population of *G.*" It is stated that the annual pay of these 18,860 public functionaries amounted

total devastation of the rest; the principal of them being Lamia, Vonitza, Nauplia, and Chalcis. All the other towns and villages were in ruins, so that the first necessity of the inhabitants of the new state was to get housed. Since that time 10 new cities have been founded, and 23 old towns, including Athens, Thebes, and Argos, have been rebuilt, besides many villages. *Athens* is the capital of the nomarchy of Attica and Boeotia, as well as of the entire kingdom. It is the residence of the king and court, and the seat of several important institutions of learning, art, and public charity. Its population has slowly increased to 48,107 in 1871. In 1866 was opened the first, and as yet the only, railroad in *G.*, a line of 7 miles, connecting Athens with the port of Piræus. The recommendation made by the Berlin Congress, in 1878, as to the rectification of the Greek frontier, excited great hopes in *G.* The Greek government, in August of that year, addressed a note to the Powers, asking them to use their influence to bring about a settlement, and various propositions having that end in view were made, but nothing definite was arrived at. There exists in *G.* a considerably larger male than female population, the former outnumbering the latter by 50,467 in 1870. The average density of population is but 73 per sq. mile.

The surface of the kingdom is in general mountainous, and the only extensive level tracts are in W. Hellas, and on the northern shores of the Morea; these, with small plains scattered through E. Greece, are the most productive districts. The climate is for the most part healthy, except in the marshy tracts adjoining the coast and lakes; and in the plains the medium temperature of the year is about 60° F. The vegetable products have a great similarity to those of the S. of Italy. Hellas possesses the best corn districts, the richest being perhaps Boeotia, though the wheat of the Morea is that in highest repute; but the supply being insufficient for the consumption, large quantities are imported. The olive and currant-grape are also cultivated extensively. The mineral products are numerous, but only an insignificant quantity of any of them is obtained at present, except copper and salt, which last is

procured in abundance in the lagoons near Missolonghi and elsewhere. Only one sixth of the area of *G.* is under cultivation; the rest, though in greater part good for agricultural purposes, lies waste. The whole superficies of *G.* has been estimated at 45,637,243 stremmas, or 15,233,082 acres, and of this total but 7,435,900 stremmas, or 2,478,633 acres, of land are in cultivation. The ground is chiefly in the hands of a few proprietors; but many of the peasants hold little patches of land of their own, which become smaller from generation to generation, in consequence of the existing law of subdivision, which is the same as that in France. On the whole, agriculture is in a very backward state. According to an enumeration made in 1879, there were only 97,176 horses, 279,445 horned cattle, 45,440 mules, and 97,335 asses in *G.* In contrast to these numbers, there were 2,291,917 sheep and 1,836,633 goats, the latter, roaming about in a half-wild state, described as the "curse of the country."

**General Commerce.** *G.* is mainly an agricultural country, and the existing manufactures are few and unimportant. *G.* is indeed naturally adapted for being a commercial rather than a manufacturing state; and though none of the rivers are navigable, and there are few roads, these are rendered less necessary than in most other countries, by the numerous bays and inlets on the coast, along which, as well as between the various islands, there is a perpetual intercourse. To this is in a great measure to be attributed the maritime habits of the Greeks, and the extent of their mercantile navy, which, including small craft, amounted in 1880 to 5,540 vessels, of an aggregate burden of 252,032 tons, navigated by about 20,000 frugal, active, and hardy seamen. Some of the Greek vessels are between 600 and 700 tons register, and a good many from 300 to 400 tons; but the great majority of them are boats of six or seven tons, having a large hatch in mid-ships. It is customary for a ship-owner to bargain with a captain and crew, taking up a certain sum at interest, generally secured on bottomry bond; with this money a cargo is purchased on the ship's account, and the profit is divided between the vessel and the crew, the latter sharing among themselves according to their special agreements. In this way the Greeks carry on extensive speculations in corn whenever bad harvests or other circumstances present openings in the ports of Turkey, Italy, Spain, or France. Besides this, they export the various productions of Turkey, *G.*, Egypt, Persia, and southern Russia, to London, Marseilles, and Trieste. The great advantage which the Greeks have over foreigners in prosecuting this trade is that of having relations and connections in the interior on whom they can rely for the collection of small parcels; and thus they avoid the impositions of agents and the profits of middlemen. The Greek trader despises nothing, and will gather a few bags of rag, or a ton or two of bones and horns, while he is chartering 50 vessels to load with corn and tallow. Then the same vessels supply Turkey, Persia, and *G.* with the manufactures of England and Germany. The extensive Greek establishments at Manchester for purchasing, examining, and packing goods, attest the importance of this branch of commerce. They have almost quite superseded the English traders here, chiefly from their thorough knowledge of the countries to be supplied, and their readiness to execute the smallest as well as the largest commissions for the shopkeepers of the East. The Greek trader slips in everywhere, neglects no business, disdains no expedient, and changes his flag as often as he finds it his interest to do so.

The principal places of trade are Syra, Patras, Piræus, Kalamata, and Nauplia. The trade of Patras is chiefly import; Hydra, Spezzia, and Galaxidi come more properly under the denomination of ship-owning ports. The exports consist of raw silk, currants, wool, oil, copper, wine, wax, mastic, and a variety of other articles; the imports, principally of corn, cotton, silk and woollen manufactures, sugar, and coffee. The commerce of *G.* averaged \$33,000,000 in the five years 1875-1879, the imports amounting to about \$22,000,000, and the exports to \$10,000,000. About one fourth of the imports come from, and one third, in value, of the exports go to, Great Britain. The principal other countries with which commercial intercourse is carried on are, in order of importance, France, Turkey, Austria, Italy, Russia, and the U. States. But the value of the imports and exports interchanged with these states is comparatively unimportant. The staple article of export from *G.* to Great Britain is currants, the value of which, in the year 1878, amounted to \$4,356,170. At the head of the other articles of export stand olive oil, and lead from the Iolian islands. Of the imports from Great Britain, about one half are manufactured cotton goods.

**Commerce with the U. States.** The commercial relations of the U. States with *G.* are very inconsiderable, — few American vessels ever making the direct voyage to any port in that country. Under the system of commercial equality with privileged nations, secured by treaty of Dec 10, 1857, which is still in force, the U. States flag could successfully compete with the flags of all other nations in the importation of wheat, flour, Indian corn, rice, sea-bread, salted meat and salted fish, tobacco, sugar, coffee, and timber; and with that of Great Britain in the importation of cotton goods. There are no data accessible upon which to base any calculation as regards the quantities of these staples, respectively, which might find a market in *G.*, but they are always in demand in the different

Greek ports. The commerce of *G.* with the U. States for the 20 years, from 1859 to 1878, was as follows: —

Years.	Imports from the U. States.		Exports to the U. S.	Total imports and exports.
	Domestic.	Foreign.		
	\$	\$	\$	\$

1876.....	143,235	.....	560,411	703,646
1877.....	190,170	6,458	523,128	719,756
1878.....	4,888,104	2,222	276,445	5,166,771
Total.....	5,446,805	11,047	4,375,359	9,832,721

The value of the principal articles imported and exported in 1878 was as follows: *Imports*, — horned cattle, \$2,200; machinery, \$305,825; fire-arms and cartridges (for the Greek government), respectively, \$1,159,390 and \$2,004,500; mineral oil, \$38,025. *Exports*, — fruits of all kinds, \$246,759; wool, \$21,153.

**Finance.** The public revenue of the kingdom for the year 1878 was 39,247,000 drachmas (\$7,008,390); and the expenditure 41,067,825 drachmas (\$7,333,540). Since the establishment of *G.* as an independent kingdom, there have been few financial terms without a deficit. The constantly recurring excess of expenditure is due in great part to the excessive number of government officials, the total, as before stated, being one twelfth of the total population. *G.* has a very large public debt, consisting in part of unpaid arrears of old loans. In the expenditure of 1878 the interest paid on the foreign debt was entered for 1,246,000 drachmas, or \$222,500, and that on the internal debt for 7,237,749 drachmas, or \$1,363,385, being a total of 8,533,749 drachmas, or \$1,523,885, equal to more than one fifth of the total expenditure. Interest is paid on but a small portion of the foreign debt. The total debt, foreign and internal, was as follows at the beginning of 1879: —

	Drachmas.
Foreign debt.....	335,513,422
Internal debt.....	94,569,480
Total.....	430,082,902
	\$78,800,515

The principal portion of the foreign debt of *G.* consists of a five per cent loan taken in 1824 by Messrs Andrew Loughnan and Co., at 59, and of another of \$10,000,000, taken in the following year by Messrs. J. and S. Ricardo and Co. at 56½. On the former the dividends have been wholly unpaid since July, 1826, and on the latter since January, 1827, a period of over fifty years. A proposal was made in 1878, by the Greek government to the holders of these loans, — chiefly English and Dutch, — to set aside \$375,000 annually for payment of dividends and of arrears, but it was on condition that assistance be given for the issue of a new five per cent loan of \$10,000,000. The loan of 1862, guaranteed by England, France, and Russia, upon the elevation of the present king of Greece to the throne, amounting to \$11,718,750, was contracted through Messrs. Rothschild. Upon this the dividends have been regularly paid, but only from reserved funds of the loan itself in the first instance, and since then chiefly from the treasuries of the guaranteeing powers, who are now, therefore, in each case heavy claimants upon the Greek government. The guarantee is not by the powers jointly, but is distinct in each case for a third of the loan. By the terms of a convention signed in 1896, it is arranged that the government of *G.*, instead of fulfilling its original engagement to provide half-yearly for the interest and sinking fund of the above loan, should pay to the three guaranteeing powers not less than \$180,000. Besides its funded debt, *G.* has a floating debt of the estimated amount of 50,000,000 drachmas, or \$8,928,570.

**Banking.** The national bank was founded at Athens in 1842, the capital being in the first instance fixed at 5,000,000 drachmas. Branches have since been opened at Syra and Patras. The exchange operations throughout the country are ruled chiefly by the transactions at Athens, where bills on

London, Paris, Marseilles, Trieste, etc., are negotiated with facility. The most serious hindrance to the progress of industry in *G.* is the high rate of interest. The legal rate is 10 per cent for ordinary loans, and 12 per cent in commercial business. High as this is, most of the loans are effected at still higher rates, and the government cannot suppress the usury.

**Money, Weights, and Measures.** The unit of money is the *drachma*, of 100 *lepta* = \$0.193. The principal weights and measures are as follows:—

The <i>Oke</i> .....	=	2.80 lbs. advoirdupois.
" <i>Cantar</i> .....	=	123.20 " "
" <i>Libre</i> .....	=	1.05 " "
" <i>Baril</i> (wine).....	=	16.33 imperial gallons.
" <i>Kilo</i> .....	=	0.114 imperial quarter.
" <i>Pike</i> .....	=	$\frac{3}{4}$ of an English yard.
" <i>Stremma</i> .....	=	$\frac{1}{2}$ " " acre.

**Seaports.** The principal are Missolonghi and Galanidi, on the W. coast of Hellas; Piræus (the port of Athens), on the E. coast of Hellas; Nauplia, Patras, and Corinth, in the Morea; and Corfu, Zante, Syra, Hydra, and Spezzia, in the respective islands of these names. Of these the chief are the following:—

**Corfu**, the ancient Corcyra, the most important, though not the largest, of the Ionian islands. It lies between lat.  $39^{\circ} 20'$  and  $39^{\circ} 50'$  N., and lon.  $19^{\circ} 35'$  and  $20^{\circ} 6'$  E.; off the S. part of the coast of Albania, from which it is separated by the Channel of Corfu, only  $\frac{1}{2}$  of a m. wide at its N. extremity, 6 m. at its S. extremity, and 15 m. in the centre. Corfu is 41 m. in length from N. W. to S. E.; its greatest breadth is in the N. 20 m. The surface is hilly; the peak of St. Salvador, in the N. W., rises 2,979 feet above the sea. The streams are small, and mostly dried up in summer; climate mild. The most elevated lands are rugged and barren, but the plains and valleys are fertile. Oil is the great staple of this isle, which has, in fact, the appearance of a continuous olive wood. The city and port of Corfu lie on the E. side of the island, on the channel, which is here about 5 m. wide. The channel has deep water throughout; its navigation, which is a little difficult, has been much facilitated by the erection of a lighthouse on the rock of Tignoso in the northern entrance, where the channel is less than a mile in width; and by the mooring of a floating light off Point Leschino, in the southern entrance. Ships anchor between the small but well-fortified island of Vido and the city, in from 12 to 17 fathoms water. Pop. of city, 26,000.

**Patras**, in the N. W. corner of the Morea, near the entrance of the gulf of Lepanto, lat.  $38^{\circ} 14' 25''$  N., lon.  $21^{\circ} 46' 20''$  E. The port lies a little to the northward of the town; but the part fronting it is unsafe, and exposed to heavy seas, particularly in winter. Vessels, therefore, go a little farther up the gulf, where there is a mole, or quay, and where they can lie close to the wharf. There is a lighthouse on the mole, which gives a flash every two minutes. It is 55 feet above high-water mark, and is visible for 7 miles. Patras has a more extensive trade than any other port of *G.* Pop. 15,000.

**Syra**, the ancient Syros, whose salubrity and fertility have been celebrated by Homer, one of the islands of the group called the Northern Cyclades, 15 m. W. from the greater Delos, its port, on the E. side of the island, being in lat.  $37^{\circ} 26' 30''$  N., lon.  $24^{\circ} 57'$  E. It is from 9 to 10 m. in length, by about 5 in breadth. Though rugged, it is carefully cultivated, and produces garden stuffs, wine, olives, figs, cotton, etc. The population, from 4,500 in 1830, had risen to 26,817 in 1879. It is indebted for this extraordinary increase of population to the convenience and excellence of its port and its central situation, which have made it a considerable commercial entrepôt. Though small, its harbor is accessible to line-of-battle ships. The holding ground is good, and it has in its centre about 10 fathoms water. Merchantmen of from 400 to 500 tons burden moor within about 100 yards of the wharves. Winds from the S. E. round to E. N. E. throw in a heavy swell; but the port is well protected from winds from all other points. A lighthouse, with a revolving light, visible 20 m. off, has been erected on Gaidaro island, about 1½ m. S. E. from the port, and there is a red fixed light on the East Mole. Most part of the trade that formerly centred at Scio is now carried on here; and the island has not only received numerous immigrants from Scio, but also from many other parts of Greece. Most European powers have consuls in Syra, and it also is the principal seat of the Protestant missionaries to the Levant. The town, which is on the N. side of the harbor, has an appearance of great bustle and animation.

**Zante**, one of the Ionian islands, is 23½ m. long, and from 6 to 11 broad. In its aspect it is the finest of these islands, presenting, when viewed from the fort above the town of Zante, a prospect of vales and eminences richly cultivated, and covered with hamlets or villages embowered in olive plantations. The port and city of Zante are situated on the E. side of the island, in lat.  $37^{\circ} 27'$  N., lon.  $20^{\circ} 54' 42''$  E. The city extends along the shore for nearly 1½ m., but it is nowhere above 200 yards in breadth, except where it ascends the hill on which the citadel is erected. The style of building is chiefly Italian; and the interior of the city displays every-

where great neatness, and even a certain degree of magnificence. It has a mole or jetty of considerable utility, at the extremity of which a lighthouse is erected; and a lazaretto, situated a little to the S. W. The harbor is capacious. Ships anchor opposite the town at from 500 to 1000 yards' distance, in from 12 to 15 fathoms, availing themselves of the protection of the mole when the wind is from the N. E. Pop. 23,000.

**Green**, one of the prismatic colors, produced by combination of blue and yellow rays, is very common in the vegetable kingdom, but very rare in the mineral. There is only one metal, copper, which affords in its combinations the various shades of green in general use. The other metals capable of producing this color are chromium in its protoxide; nickel in its hydrated oxide, as well as its salts, the seleniate, arseniate, and sulphate; and titanium in its prussiate.

**Green Dyes.** See DYEING.

**Green Pigments.** Several of the *G.* pigments of commerce are obtained from copper. Oxide of chromium furnishes some which are very beautiful. Many are formed by the mere mechanical admixture of blue and yellow pigments. The bright blues and yellows, when mixed in this way, produce the liveliest *G.*; orange, or red and blue, and the yellowish browns and blue, the more dingy *G.* In this way are produced all the extemporaneous *G.* of the artist. Nickel and titanium also furnish *G.* colors, but these are not in common use. The following list embraces all the best known and most useful *G.* pigments: *Barth's G.* consists of yellow lake, Prussian blue, and clay, ground together. *Bice G.*, same as mountain *G.* *Bremen G.* is properly *G.* verditer, but other preparations are frequently sold under the name. *Brighton G.* is a mixture of impure acetate of copper and chalk. *Brunswick G.* is probably a crude chloride of copper, but a mixture of carbonate of copper and alumina or chalk is commonly sold under the name. *Chrome G.* The superb *G.* pigment used by enamellers under this name is the *G.* oxide or sesquioxide of chromium. *Emerald G.*, same as Schweinfurt *G.* *Frise G.* resembles Brunswick *G.* *Gellart's G.* is a mixture of cobalt blue and flowers of zinc with some yellow pigment. *Imperial G.*, same as Schweinfurt *G.* *Iris G.* is a very fugitive pigment, prepared by grinding the juice of the petals of the blue flag with quick-lime; *Lake G.* (see LAKE); *Mineral G.*, same as mountain *G.* *Mitis G.* is another of the many synonyms of Schweinfurt *G.* *Mountain G.* is properly the native *G.* carbonate or bicarbonate of copper (malachite) ground to powder, either with or without the addition of a little orpiment or chrome yellow. That of commerce is commonly prepared by adding a solution of carbonate of soda, or of potassa, to a hot mixed solution of sulphate of copper and alum. *Neuwieder G.* is Schweinfurt *G.* mixed with gypsum or sulphate of baryta. *Prussian G.* is a mixture of Prussian blue and gamboge. *Rimman's G.* resembles that of Gellart. *Sap G.* is a very fugitive pigment, prepared from the juice of buckthorn berries. *Scheel's G.* is an arsenite of copper. *Schweinfurt G.* is the aceto-arsenite of copper, prepared as follows: Acetate of copper and arsenious acid, equal parts, are each dissolved separately in the least possible quantity of boiling water, and the solutions mixed whilst still as hot as possible; an olive-green precipitate falls, which, by being boiled in the liquor 5 or 6 minutes, changes to a dense granular powder of a superb green color. This is a very fine, permanent *G.* pigment. "A great deal of needless alarm," says Watts, "has been excited about its supposed deleterious effects. It is extensively employed for staining wall-papers,

and persons inhabiting rooms thus papered are said to have had their health seriously deranged by the arsenical fumes evolved from it. Now, it is utterly impossible that arsenic could volatilize from such a compound at ordinary temperatures; it does not decompose at any temperature below redness." It is, however, probable that the air of such apartments is sometimes charged with the poisonous pigment through its becoming detached from the paper. To breathe an atmosphere so impregnated would be dangerous. The use of paper colored with Scheele's or Schweinfurt *G.*, especially the kind called "flock," should, therefore, be carefully avoided. *Verona G.* is the mineral called *G. earth*. *Vienna G.*, the same as Schweinfurt *G.* See also ANILINE COLORS, VERDIGRIS, and VERDITER.

**Greenback**, a popular name for the paper-money first issued by the government of the U. States in 1862, the engraved backs of which are printed with green ink.

**Green Bay and Minnesota R.R.** runs from Green Bay, Wis., to Winona, Minn., 213.9 m. This Co., whose offices are in Green Bay, was chartered in 1866 and the road opened in 1873. A portion of the La Crosse, Trempealeau, and Prescott R. R. from Winona to La Crosse, 29.7 m. in length, is operated under lease by the Co., which is at present in the hands of a receiver. *Financial statement*: Cap. stock, \$8,000,000; funded debt, \$3,979,300 as follows, — 1st mortgage bonds, issued 1870, \$3,200,000, payable 1900, interest 7% (Aug. and Feb.); 2d mortgage bonds, issued 1873, \$779,000, payable 1893; interest 8% (May and Nov.).

**Green-Cloth**, green baize, etc., used for covering tables.

**Green-Crops**, plants which are grown on a farm to be consumed before they are fully ripe or come to maturity, as turnips, carrots, etc.

**Green-Earth**, a variety of talc, also called *sela-donite*, known by artists under the name of mountain green. See GREEN.

**Green-Ebony**, a wood obtained from the *Jacarana ovalifolia*, a native of the West Indies, and used both as a hard turning-wood and as a dye-stuff.

**Green-Gage**, a kind of plum of a green color; the *Claudiana* variety of the *Prunus domestica*.

**Green-Grocer**, a retail dealer in vegetables and fruit in their fresh or green state.

**Greenheart**, a common tree of Guiana, the *Nectandra rodiei*; its timber, squaring from 18 to 24 inches, can be procured without a knot from 60 to 70 feet long. It is a fine-grained hard wood, well adapted for the planking of vessels, house frames, wharves, bridges, and other purposes, where great strength and durability are required. It is the best timber for resisting tensile and compressive strains, and is therefore well adapted for keelsons of ships, and beams of all kinds. The black greenheart is considered more durable than the common greenheart. The bark yields biberine, the sulphate of which is used like the sulphate of quinine.

**Greenhouse**, a conservatory or glazed house for rearing and protecting plants from changes of temperature.

**Greenland**. See DENMARK.

**Greenock**. See GREAT BRITAIN (Seaports).

**Green Paints or Pigments**. See GREEN.

**Green-Room**, the actors' retiring or meeting room in a theatre.

**Greens**, a common name for small young cabbage which have not formed the leaves into full hearts.

**Green-Sand**, a silicious stone found in the Blackdown Hills of Devonshire, England, used as a whetstone for scythes, etc.

**Greensward**, a grass-plot.

**Green-Tea**, a commercial variety of tea imported from China, of which there are several kinds; the principal being Twankay, an inferior description, Hyson-skin, Hyson, and young Hyson, imperial, and gunpowder. See TEA.

**Green Turtle**. See TURTLE.

**Greenville and Columbia R.R.** runs from Columbia, S. C., to Greenville, S. C., 143.5 m., with a branch from Cokesburg to Abbeville, 11.5 m., and another from Belton to Anderson, 9.8 m.; total, 164.8 m. The Laurens R.R. is operated by this Co., which has also a controlling interest in the Blue Ridge R.R. This Co., whose offices are in Columbia, was chartered in 1846, and the road was opened in 1853. The road passed into a receiver's hands in 1878. *Financial statement*: Cap. stock, \$1,515,165.54; funded debt, \$2,178,763.32, consisting of, — past due, 1st mortgage bonds, \$236,000; 2d mortgage bonds and certificates, \$103,060.58; non-mortgage bonds, \$140,000; state guaranteed bonds and certificates, \$1,413,071.55; funded interest bonds, \$163,131.19; and 1st mortgage bonds, payable 1895, \$123,500.

**Greenwich**, a fire-insurance Co., located in New York City, organized in 1834, reorganized under the general act and an amended charter, 1864. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$200,000; net surplus, \$344,301.10; total cap. and surplus, \$544,301.10; risks in force, \$46,440,586; premiums, \$203,305.23; premiums received since the organization of the Co., \$3,186,069.26; losses paid, \$1,281,614.95; cash dividends paid to stockholders, \$1,518,000; cash dividends paid during the year, \$60,000.

**Greffier**, a registrar, or recorder in a French court of justice.

**Gregarious**, herding together, or living in flocks, as domestic cattle, birds, etc.

**Grege**, a French term applied to raw silk.

**Grelin** [Fr.], a small cable or line for a boat.

**Grenache**. See ROUSSILLON (WINE OF).

**Grenade**, a hollow ball or shell of metal, filled with powder, having a burning fuse attached, thrown by hand amongst enemies.

**Grenadier**, a tall foot-soldier wearing a high cap; one originally employed to throw grenades.

**Grenadine**, a gauzy dress-goods, of silk or wool, plain, colored, or embroidered.

**Grenat** [Fr.], dried lemon-peel.

**Greyhound**, a slim-made dog kept for coursing, remarkable for swiftness, strength, and sagacity in pursuing game.

**Griddle, Riddle**, a miner's wire-bottomed sieve for separating the ore from the halvans.

**Gridiron**, a kind of frame for drawing up a ship on to be docked and repaired. — A frying and grilling iron grated frame for cooking chops, steaks, fish, etc., over a fire.

**Grilling**, the operation of broiling meat over a fire.

**Grilse**, a young salmon.

**Grimellino**, a small money of account in Tripoli, of 4 aspers.

**Grinder**, a sharpener and polisher of edge-tools. — The large teeth that masticate food. Elephant's grinders are used for making knife-handles.

**Grindery Warehouse**, the name in England for a finding-store.

**Grinding**, the operation of reducing substances to powder by friction or attrition. *G.* is the most unhealthy of all trades in steel manufactures, ow-

ing to the tendency of metallic and stony particles to enter the lungs. At Sheffield a *G.* mill or establishment is usually called a *wheel*; the distinct rooms in it are called *hulls*; and the distinct grindstones in each hull, *troughs*. One system of steam-power works all the grindstones; and the grinder pays a rent for the space and the power supplied to him. The grindstones are from 6 to 24 inches in diameter, turning on square iron horizontal spindles. They are made of various kinds of sandstone grit, and each kind suited for *G.* some particular sort of steel work. In most instances the grinder sits astride a plank called a *horse*, and has facilities for applying water to the grindstone while using it. Some steel goods require large grindstones, some small (razors the smallest); some need wet grinding, some dry. Most fine cutlery, as well as forks and needles, require dry *G.*; and this renders these trades particularly hurtful, on account of the dry steel dust floating about, a fork-grinder seldom surviving his thirtieth year. Small grindstones give concave surfaces, which in their turn give sharper edges. Large stones grind more rapidly than small, and dry more rapidly than wet; the grinder knows by experience which is best. Other kinds of *G.* are very numerous, — such as *G.* glass lenses, glass plates, telescopic specula or reflectors, diamonds and other gems, plane surfaces of cast or rolled iron, gun-barrels, steel pens, needles, etc. See the headings relating to the substances operated upon; see also *EMERY*. — In the laboratory, the term is chiefly applied to powdering by means of a mill or by mechanical power, in opposition to simple pounding or trituration in a mortar or with a slab or muller. All the principal powders, paints, etc., sold by the druggist and colorman, are reduced in the drug or color mill.

**Grinding-Slips**, hones; a kind of oil-stone.

**Grindstone**. See *GRINDING*.

**Gripes**, bars of iron with lanyard rings and claws, by which a large boat is lashed to the ring-bolts of the deck.

**Grisette**, a common brown French stuff fabric, worn by females of inferior class; whence the transfer of the name to the wearer.

**Grist**, as much grain as is carried to the mill at one time for family use, or the meal it produces.

**Grist-Mill**, a name for a flour-mill; especially a mill for grinding grists, or portions of grain brought by different customers.

**Grit**, hard sandstone employed for millstones, grindstones, pavement, etc.; gravel. — The coarse part of meal.

**Gritty**, earthy; containing sand or grit; flour or meal having pieces of stone, etc., mixed with it.

**Groat**, a small English silver coin, equivalent to 4*d.*, first minted in the reign of Edward I. A very large quantity of *G.* were coined in 1854–5, and none since.

**Groats**, decorticated oats; hulled and peeled barley.

**Grocer**, a dealer and vender of sugar, spices, dried fruits, and other comestibles, or articles of food for the table; usually combined with the sale of coffee and tea.

**Groceries**, the comestible wares, or general commodities sold by a grocer.

**Grog**, a sailor's name for rum, whiskey, or other spirituous liquor, diluted with water and unsweetened.

**Grogram**, a fabric made of silk and mohair, and having a coarse grain or texture.

**Groin**, a framework of wood across a beach to

retain the accumulated shingle. — The point of junction in two semi-cylinders or arches.

**Grommet**, a ring formed of rope, by laying round a single strand; used to fasten the upper edge of a sail to its stay.

**Groom**, a stable attendant; one who has the care of horses; a gentleman's servant or outrider.

**Groove**, a channel, or long hollow furrow cut by a tool. — A shaft or pit sunk by miners.

**Grooved**, furrowed or channelled.

**Gros-de-Naples** [Fr.], a plain silken fabric made of organzine silk, and woven with much neatness and care.

**Gross**, in merchandise the whole weight of goods, including box, package, baling, etc. — The number of 12 dozen, which is the small gross, but the great gross is 12 times 12 dozen.

**Ground**, land. — The color first put on the surface. — The prevailing color of a fabric, building, etc. — The first layer of color in a painting. — Flush strips in plastering for the attachment of moulding and other finishing. — In navigation, to touch the bottom. — In the plural: the dregs or feculencies deposited at the bottom of liquids; as coffee-grounds.

**Ground-Bait**, pastry, bread, or other substances, cast to the bottom of water to entice fish.

**Ground-Blood**, a preparation of blood largely used as a fertilizer, consisting of blood divested of its water, and ground.

**Ground-Floor**, the story or floor of a house level with the ground.

**Ground-Glass**, glass whose surface is ground, so as to break up the pencils of light passing through it, preventing the passage of a distinct image. Lamp globes are ground in order to mellow and disperse the light passing through them. The process is done mechanically or chemically: the wheel, sand-blast, by rotating with pebbles inside, or by fluoric acid. — *E. H. Knight*.

**Ground-Joint**, a joint for fitting certain surfaces by rubbing them with fine-grained emery and oil.

**Ground-Nut**. See *PEANUT*.

**Ground-Plan**, the surface representation of the divisions of a building.

**Ground-Plot**, the land on which a building stands; the plan of the ground.

**Ground-Rattan**, a kind of cane, the stem of *Rhapis flabelliformis*.

**Groundsel**, a common wild plant, the *Senecio vulgaris*; the stalks, containing the ground buds, seeds, and leaves, are collected and sold to feed canaries and other cage-birds. — The timber or sill of a building resting on the earth.

**Ground-Tackle**, a general name for the appliances and gear used in securing a vessel at anchor, comprising cables, ways, springs, anchors, etc.

**Ground-Tier**, the lowest tier of casks in a vessel's hold. — The pit range of boxes in a theatre.

**Groundwork**, the earthwork or foundation; the commencement of any operation.

**Grouse**, a large family of birds, many of which are much esteemed. To this family belong the Wood *G.*, Cock of the Wood or Capercaillie (*Tetrao uregallus*); the prairie-chicken (*T. cupido*) of our western prairies; and the American partridge (*Bonasa umbellus*).

**Grout**, coarse meal; pollard. — A thin mortar, a mixture of quick-lime and fine sand, used for mouldings and finishing ceilings.

**Grove**, a small shady wood.

**Groyne**, a sea-wall, or defence against the encroachments of the tide. See *GROIN*.

**Gruan** [Fr.], oatmeal; water-gruel.

**Gruans**, wooden vessels used in salt manufactories in France. — Wheat flour coarsely ground, so as to free it from husk.

**Grub-Axe**, a hoe or field tool for digging up weeds.

**Grubber**, a kind of heavy cultivator, used in Scotland for stirring and loosening the soil to plough depth.

**Grub-Saw**, a hand-saw used for sawing up marble slabs into strips, such as shelves, mantel-pieces, etc.

**Grubstone Mortar**. See BETON.

**Grunter**, an iron rod bent like a hook, used by iron founders.

**Gruyère**. See CHEESE.

**Guacho**, a South American mounted herdsman, or cattle-hunter.

**Guadeloupe**, or **Guadaloupe**, one of the leeward group of islands in the West Indies, belonging to France, and situated in lat.  $16^{\circ} 20' N.$ , lon.  $62^{\circ} W.$  It consists properly of two islands, separated from each other by a narrow channel, about 5 m. in length by from 30 to 100 yards wide, and with depth sufficient for vessels of 60 tons. This channel, called *La Rivière Salée*, or Salt River, runs nearly N. and S., and has a large bay at each end, that on the N. being called the *Grand Cul-de-Sac*, that on the S. the *Petit Cul-de-Sac*. The western or larger island, called *G.* proper or *Basse Terre*, is 27 m. in length by 15 m. in breadth; the eastern, or *Grande Terre*, is nearly 30 m. long by from 10 to 12 broad. Total area (with dependencies), 1,645 sq. m. The government consists of a governor, with a privy council of 6, and a colonial council of 30, members. Pop. 151,594.

*G.* proper is of volcanic formation, and is traversed from N. to S. by a ridge of hills having a medium height of 2,295 feet. Its principal peak is *La Soufrière*, an active volcano 5,108 feet high. It is copiously watered by numerous small streams, two of which, the *Goyade* and the *Lezarde*, are navigable for small craft. The soil is fertile, and the surface is agreeably diversified by hill and dale, wood and garden. The products, natural and cultivated, are those of the West Indies generally. The principal town, *Basse Terre*, stands on the S. W. coast. It is the residence of the governor, and has some fine public buildings, fountains, and gardens, and has about 8,000 inhabitants. *Grande Terre*, unlike *G.* proper, is marshy, sterile, and flat, nowhere rising more than 115 feet above the sea. Its chief town, *St. Louis*, or *Pointe à Pitre*, the former capital of the island, is at the S. entrance to the Salt River, and has an excellent harbor. It formerly contained about 15,000 inhabitants, but was almost entirely destroyed by an earthquake in 1843. The climate is humid, and hurricanes and earthquakes are frequent. The rainy season lasts from the middle of July to the middle of October. The chief exports are sugar, molasses, rum, cotton, coffee, dye-woods, and copper. The sugar crop amounts to about 60,000 hogsheds annually.

The commercial intercourse of *G.* with the U. States is relatively considerable. For the year 1878 the value of imports from this country was \$1,569,880, and of exports \$2,381,059. The principal articles entering in these figures were as follows: *Imports from the U. States*: Agricultural implements, \$2,163; horses, \$17,668; mules, \$82,670; bread-tuffs, \$593,370; cotton goods, \$40,674; hay, \$1,716; ice, \$8,730; leather of all kinds, \$53,865; saddlery, \$1,680; manures, \$11,531; matches, \$1,345; mineral oil, \$39,942; plated ware, \$1,533; bacon and hams, \$29,861; salted beef, \$20,693; fresh beef, \$42,537; butter, \$3,188; dried fish, \$71,211; pickled fish, \$16,993; cured fish, \$14,598; lard, \$56,818; preserved meat, \$3,468; pork, \$77,074; onions, \$1,375; potatoes, \$1,984; tobacco leaf, \$102,464; tobacco (manuf.), \$4,988; wood (boards, laths, shingles, etc.), \$231,245; household furniture, \$10,795. *Exports to the U. States*: Gold coin, \$651,220; fruits, \$4,135; salt, \$1,194; brown sugar, \$2,807,827; molasses, \$41,000.

The government of *G.* comprises, besides that island, those of *Marie-Galante*, *Desirade*, *Les Saintes*, and the N. portion of *St. Martin* (the S. portion belonging to the Dutch). *Marie-Galante* lies 14 m. S. S. E. of *G.*, and is about 12 m. in length by 8 in breadth. It is traversed from N. to S. by a range of hills running parallel to the E. coast, where it presents a front of high and precipitous rocks. The W. and N. sides of the island are level; and parallel with the former is a narrow lagoon, 7 or 8 miles in length, separated from the sea by a low, narrow tract of land. The island abounds in woods, particularly the wild-cinnamon tree. Its principal town, *Grand-*

*bourg*, or *Basse Terre*, stands near the S. W. point. — *Desirade*, or *Désada*, lies about 4 m. E. from the S. E. extremity of *Grande Terre*, and is about 8 m. long by 3 wide. It rises from the sea with a steep ascent, and then extends in a table-land, which consists of limestone rocks, in which many caverns occur, but it is without water. The soil in some places is of a deep black mould, and fertile; in others it is sandy and unproductive. The only anchorage is at the *Anse-Galet*, on the E. side of the island. — *Les Saintes* are a group of rocky islets 6 or 7 m. S. of *G.*, and consist of lofty and steep peaks, some of which are united by flat ground and ridges of inferior elevation. The two largest are called *Terre d'en Haut* and *Terre d'en Bas*. — *St. Martin* is a small island immediately S. of the British island of Anguilla, in lat.  $18^{\circ} 5' N.$ , and lon.  $63^{\circ} 6' W.$  Its form is nearly that of an equilateral triangle, each side being about 7 m. in length. It is deeply indented with bays and lagoons, some of which afford good anchorage. The surface is generally hilly, the highest point being 1,361 feet above the sea.

**Guaicum**, a fine evergreen tree (*Guaicum officinale*) of the West Indian Islands, particularly Cuba, San Domingo, and the S. side of Jamaica. The wood is remarkable for its hardness, toughness, and durability; qualities which render it particularly valuable for many purposes. It is known in commerce as *lignum vite*. This wood and a resin obtained from it are official in our pharmacopœias, and are commonly known in the shops respectively as *G.-wood* and *G.-resin*. The latter is generally procured by heating the wood, either by boiling chips in salt water, or more commonly by burning hollow billets, and catching the resin as it flows out from them. It also exudes to some extent spontaneously, and especially so when the tree is cut or wounded in any way. *Imp. free.*

**Guallaga**, a name in San Domingo for the *Zamia media* plant, from the root of which starch is obtained and exported.

**Guana**, a common name for a large species of tree lizard, the *Iguana tuberculata*, which is esteemed for its delicate flesh, and the skin is often tanned.

**Guanaco**, a variety of the alpaca, the *Auchenia huanaca*.

**Guano**, a substance extensively used as a manure, consisting of the partially decomposed excrement of certain aquatic birds, chiefly the common penguin, which congregate in countless numbers on the barren and uninhabited islets and rocks of South America and the coasts of Africa. It abounds in ammonia and the phosphates, and is undoubtedly the richest natural manure known. Under judicious application, the increase of the crops of grain, turnips, potatoes, and grass consequent upon its use is said to be about 55 %. *G.* is particularly adapted to horticultural and floricultural improvement, by its relative cleanliness and facility of application. Several of the South American *G.* beds are now exhausted, but new varieties are constantly being introduced; and although the qualities are continually varying, *G.*, on the whole, may be divided into two classes, the one characterized by the abundance of ammonia, the other by that of phosphates, the Peruvian and Angamos being characteristic of the former, and the Saldanha Bay and Bolivian of the latter. In selecting a *G.* the following points ought to be attended to: 1st. The *G.* should be light-colored and dry, coloring very slightly when squeezed together, and not gritty. 2d. It should not have too powerful an ammoniacal smell, and should contain lumps which, when broken, appear of a paler color than the powder. 3d. A bushel should not weigh more than from 56 to 60 pounds. These characters are, however, imitated with great skill, so that they cannot be implicitly relied upon, and they are applicable to Peruvian *G.* only.

*Adulteration and Test.* *G.*, owing to its high price, is very commonly adulterated, or is in an advanced stage of decomposition when sold. Much of what is vended under the name is

altogether a fictitious article. These artificial mixtures are made to look so like genuine *G.*, that the mere practical man, who goes only by their appearance, is very often deceived by them, and, owing to the failure of his crops in consequence, is led to distrust the efficacy of *G.* as a manure. Vessels which sail hence for the *G.* stations are very commonly ballasted with rough gypsum, or plaster of Paris. This substance is mixed with the *G.* as it is loaded, and enables the importers to deliver from the vessel a "nice-looking, light colored article." Purchasers of *G.* are very desirous of having it delivered from the vessel, as they believe they thus obtain it pure. The favorite material for the adulteration of *G.*, at the present moment, is a variety of umber, which is brought from Anglesea (an island of Wales) in large quantities. The rate of admixture is said to be about 15 cwt. of umber to about 5 cwt. of Peruvian *G.*, from which an excellent-looking article is manufactured, which is sold under the name of "African *G.*" Pure *G.* has a pale-brown color, a more or less offensive odor, and the average sp. gr. of 1.63 to 1.64. If the sp. gr. exceed 1.75 it is either damaged or adulterated; and if it is less than 1.62 it contains an undue quantity of moisture. The best is neutral to test-paper, and sometimes has even an acid reaction; but that of commerce has generally an alkaline reaction, owing to the presence of free ammonia, and, in consequence, turns turmeric paper brown, and gives white fumes when a glass rod dipped in hydrochloric acid is held over it. Triturated with quick-silver or caustic potassa, good *G.* evolves a powerful odor of ammonia; digested in water, fully one half of it is dissolved; dried by the heat of boiling water, it does not lose more than from 7 to 9 % in weight; and burned upon a red-hot shovel, it leaves a white ash, not a red or dark-colored one. As its value to the agriculturist depends chiefly on its richness in ammonia, potassa, and phosphoric acid, the analysis of *G.* for practical purposes may be reduced to an assay for these articles. Indeed, the presence of ammonia (the most valuable of them), in the proper quantity, may be fairly taken as evidence of the presence of the rest. The following method of testing *G.* is both simple and accurate: 100 gr. of the sample for examination (fairly selected) are distilled along with about 75 gr. of fresh-slaked quick-lime, and a little water, in a small matrass connected with a tubular triple bulb-condenser, containing cold distilled water, and immersed in a basin of ice-cold water (Fig. 250). The condenser is charged by plunging

Fig. 250. — ANALYSIS OF GUANO.

one of its extremities into the water, and sucking at the other until the liquid reaches the level indicated in the margin. A very gentle heat only, cautiously increased, need be employed. After the process is over, the strength of the solution of ammonia found in the condenser is tested by taking its density in a small specific-gravity bottle. This furnishes the percentage of ready-formed ammonia sufficiently accurate for all ordinary purposes, provided proper care is taken.

The imports of *G.* into the U. States for the year 1873 amounted to 23,123 tons, valued at \$849,607, to which Peru contributed 20,982 tons, Venezuela 1,221 tons, and British Honduras 791 tons. *Imp. free.*

**Fish-Guano.** A manure of that name, said to be very effective, is manufactured by the U. States Menhaden Oil and Guano Association, in Maine, Massachusetts, Rhode Island, Connecticut, Long Island, and New Jersey. According to statements from a report of that Association, 1,478,634 barrels of fish caught in one year, averaging 250 fish per barrel, have given, besides 3,372,837 gallons of oil, 50,976 tons of *F-G.* A foreign market has been recently opened for this manure, and cargoes have been shipped from Maine to Liverpool.

**Guarana**, an alimentary and medicinal substance prepared from the seeds of *Paullinia sorbilis*, a Brazilian tree. The dried seeds, deprived of their aril, are pounded and kneaded into a mass, which is afterward made into oblong or rounded cakes, called *G. bread*. These cakes are used as we

use chocolate, — mixed with water and sugar, and drank as a beverage. In Brazil this beverage is largely consumed, both on account of its nutritive qualities, and for its stomachic, febrifugal, and aphrodisiac effects.

**Guarantee**, he to whom a guaranty is made.

**Guarantor**, he who makes a guaranty; one who is bound to another for the fulfilment of an engagement by a third party.

**Guaranty**, an engagement to perform some act, or pay some debt, in case another person primarily liable fails to do so. To make such an obligation binding, there must be some good consideration moving from the party with whom it is made; as the delivery of goods to, or work to be done on credit for, the person on whose behalf the guaranty is given. It must be in respect of a contemporaneous or future debt or act. If a guaranty be made in respect of a debt already incurred, there must be a new consideration to support it. A consideration, however, need not be expressed; for if it can be fairly implied from the circumstances, or the language used, it will ordinarily be sufficient. It is sufficient if the person for whom it is given receive a benefit, or may receive a detriment. The Statute of Frauds, re-enacted almost in terms in the several States, stipulates that a defendant cannot be charged to answer for the debt, default, or miscarriage of another person upon any special promise, unless the agreement upon which such action shall be brought, or some memorandum or note thereof, shall be in writing, and signed by the party charged therewith, or some other person duly authorized by him. This statute only applies, however, to engagements in which the guarantor is only liable conditionally upon the default of some other person: where he is liable co-extensively with the other party in the first instance, it does not apply. The construction of all such obligations is never extended beyond their obvious meaning, and they are only understood to apply to future, unless they expressly include past transactions. All their conditions and limitations must be carefully regarded, otherwise they become void. If so expressed or intended, however, such obligations may be of the most unqualified character; they may be unlimited in amount, and indefinite as to time. When the guarantor is compelled to pay, he has an action of relief against the principal debtor; but that party, being primarily liable, must first be sued by the creditor; and whatever he does toward the extinction of the claim of the creditor, or whatever the creditor recovers from him or his estate, goes so far to relieve the guarantor, who can also plead against the creditor any defence which could be competently pleaded by the principal debtor. Where more persons than one are bound together in a *G.* obligation, any of them seeking relief from the others of a share of his loss must communicate to them a share of any security which he may hold over the estate of the principal debtor, or of any abatement he may have obtained from the creditor. A *G.* obligation may be extinguished by the extreme neglect of the creditor; as, for example, by his failing to take advantage of a security in his power, omitting to negotiate a bill, inadvertently giving up funds of the principal debtor over which he had a right of lien or retention, or renouncing any security over his estate. In like manner, if he compound with, or discharge the principal debtor, without the concurrence of the guarantor, the *G.* is at an end.

**Guarapo**, a common beverage of the lower orders in Venezuela, made from the juice of the

sugar-cane, or with sugar and water which has undergone the vinous fermentation.

**Guard**, that which secures against injury, de-facement, or loss; whence, the bowl or basket of a sword-hilt, or that which serves as a protection for the hand. — An ornamental hem, lace, edging, seam, or border. — The chain or ribbon which serves to fasten a time-piece, etc., to one's person; as a watch-*G.* — A kind of fine wire-grating or network, placed opposite to, or over, a hearth, etc.; as a fire-*G.* — A railing placed at the sides of a vessel, to prevent persons from falling overboard. — A safety-lock of a fowling-piece to prevent the accidental dropping of the hammer. — In machinery, a light frame in which the nuts of bolts fit to prevent their unscrewing by the vibration of the engine. — In bookbinding, one of the slips of paper bound in with a blank book to thicken it at the back, when the leaves are intended to contain slips, or drawings.

**Guard-Boat**, a row-boat in a harbor, or among vessels at anchorage.

**Guardian**, a protector; one chosen or appointed, by statute or by will, to take charge of the estate or education of an orphan or ward, or a person who is imbecile or otherwise incompetent to manage his own affairs.

**Guardian**, a fire-insurance Co., located in New York City, organized in 1865. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$200,000; net surplus, \$35,343.87; risks in force (fire), \$9,983.216; premiums, \$64,235.34; inland risks \$16,250; premiums, \$593.75; premiums received since the organization of the Co., \$1,105,722.02; losses paid, \$664,166.70; cash dividends paid to stockholders, \$171,000.

**Guatemala**, one of the five republics of Central America, extending from lat. 13° 50' to 18° 15' N., lon. from 88° 14' to 93° 12' W. It is bounded N. by the Mexican State of Chiapas, E. by British Honduras and the Caribbean Sea, S. by the republics of Honduras and San Salvador, and S. W. by the Pacific Ocean. By the terms of the constitution proclaimed Oct. 2, 1859, the legislative power is vested in a congress of two chambers, called the Council of State and the House of Representatives. Both chambers are elected for 4 years, the House of Representatives by the people, and the Council of State by the House. The executive is vested in a President, also elected for 4 years. The area of *G.* is estimated at 41,830 sq. m. According to a rough enumeration taken on Jan. 31, 1872, there were at that date 1,190,754 inhabitants, of whom 360,608 were of European descent, and 830,146 aborigines, or Indians. *G.* is administratively divided into 17 provinces, of which 3, Escuintla, Sololá, and Suchitepequez, are on the Pacific Ocean, 1, Yzabal, borders the Atlantic, and the rest are inland. The capital of the republic and seat of the government is Santiago de Guatemala, or Guatemala la Nueva, with 45,000 inhabitants, a tenth of them of European origin. The former capital, Santiago de Caballeros, or Guatemala la Antigua, which had once a population of 60,000, was partly destroyed by fire and earthquakes in 1773, and has now only 20,000 inhabitants.

The surface of *G.* is wholly mountainous, the main chain of the continuation of the Andes traversing it from S. E. to N. W. at an inconsiderable distance from the Pacific shore, and branching off in various ramifications toward the Atlantic; forming many valleys, but enclosing few plains. Along the main chain occur numerous volcanoes, all near the Pacific. The culminating point of the surface is in N. lat. 15° 30', between the towns of Totonicapán and Gueguetenango. The

E. border of the plateau descending to the Gulf of Honduras is cut by deep valleys, which extend to a great distance, and in some places advance to the very shores. The country lying to the W. and the N. W. of the Golfo Dulce is a low plain, while all between the plateau and the Bay of Honduras is a succession of ridges and valleys. In many places the shore is rocky, with rocky barriers lying off it. Numerous streams drain this State. The most important are the Lacantun, forming part of the Mexican boundary; the Motagua and the Polochic, which fall through the Dulce into the Bay of Honduras. The most important lakes are the Dulce, advantageous for foreign trading vessels; the Amatitlan, 15 m. S. E. of *G.*, is 9 m. by 3, of great depth, and is much resorted to as a bathing-place by the inhabitants of *G.* from February till April; near it there are several mineral and hot springs, the Atitlan, 80 m. N. W. of the city of *G.*, is about 20 m. long by 9 broad, surrounded by lofty heights, including the volcano of Atitlan, and is remarkable for its very great depth, and being without outlet, though several small rivers enter it; the Paten, near the frontiers with Yucatan, about 30 m. long, and 9 broad. The climate of the table-land is that of perennial spring, the thermometer scarcely varying throughout the year, and it resembles very much the climate of Valencia in Spain in almost every particular. In the northern part of the State, in what is called *Los Altos* (the highlands), the average is lower than any other part of the country. Snow sometimes falls in the vicinity of Quetzaltenango, the capital of this Department, but soon disappears, the thermometer seldom remaining at the freezing point for any considerable time. In the vicinity of the city of *G.*, the range of the thermometer is from 55° to 80°, averaging about 72° F. Vera Paz, the N. E. Department of *G.*, and embracing the coast below Yucatan to the Gulf of Dulce, is nearly 10 degrees warmer. This coast from Belize downward to Isabel and San Tome is hot and unhealthy. From May till October is the rainy season. Thunder prevails in June, and terrific storms from the S. W. sweep along the Pacific coast in August and September. Earthquakes are very frequent. The soil is generally very fertile, producing excellent rice, and all the cereals in great variety and abundance. Agriculture has remarkably progressed during the last ten years. As articles of commerce, the most important products are coffee, cochineal, and indigo. Cotton, cacao, sugar, vanilla, and tobacco are grown in considerable quantities. The cultivation of coffee is largely increasing, while that of cochineal is being abandoned. The table-land is almost destitute of trees and even bushes, except on the declivities of the hilly ranges which so extensively traverse it. Trees of very large size form extensive forests on the lower lands along the

Fig. 251. — SEA-LAVENDER.  
( $\frac{1}{2}$  natural size.)

Pacific. These are a source of great natural wealth. Among the trees the most valuable are the cedar, mahogany, Brazil, Santa Maria, pimento, gualicum, etc.; and abundance of medicinal plants are also found and turned to some account. The vegetation is luxurious and vigorous along the low tract by the Bay of Honduras. There abound cactuses, palms, ulmo-sas, etc. Mixed with these are numerous herbaceous flowers, of the most varied colors and elegant forms, of which the sea-lavender, *Statice elata* (Fig. 251) is a splendid and striking specimen. Sheep are reared in considerable numbers, especially over the northern districts, and their wool is used for native manufactures. The horse is small, hardy, and handsome;

and mules are numerous, being the chief beasts of burden. Pigs and poultry are very abundant, and of excellent quality. Salt is manufactured along the coast of the Pacific. Jasper, marble, and brimstone are obtained in considerable quantity in the vicinity of some of the volcanoes. Lead is worked by the Indians in Totonicapán. The manufactures are mostly limited to those for domestic use. The cotton manufacture is almost confined to the departments of *G.* and Sacatepéc. Coarse woollen cloth is extensively manufactured, especially *grrega*, which is made into a peculiar black called *poncho*, in which much taste is displayed.

**Commerce.** The commercial intercourse of *G.* is chiefly with Great Britain and the U. States, the exports consisting of coffee, cochineal, indigo, and other agricultural produce, and the imports chiefly of textile fabrics. The exports for the year 1877 were of a total value of \$3,773,183.74; comprising coffee (\$3,358,956.16), cochineal (\$1,693), woollen goods (\$115,939.20), muscovado (\$28,303), hides (\$62,343.84), etc. These commodities were distributed among the various markets as follows: Great Britain, \$1,073,977; California, \$1,087,531; New York, \$193,252; Germany, \$819,910; France, \$311,870; Belize, \$181,690; Central America, \$127,308; South America, \$30,909. The chief sources of the imports and the values of these were as follows in the same year: Great Britain, \$1,208,894.87; France, \$458,162.44; Germany, \$317,367.60; United States, \$378,753.21.

The value of the commercial intercourse of *G.* with the U. States is not reported in the annual reports published by the Treasury Department at Washington, which summarize, under the heading of "Central America," the commerce of the 5 states of Costa Rica, *G.*, Honduras, Nicaragua, and San Salvador. The commercial intercourse of the whole of Central America with the U. States, for the year 1878, is as follows: *Exports from Central America to the U. States*.—chemicals, \$20,509; cocoa, \$23,415; cochineal, \$5,311; coffee (13,868,955 lbs.), \$2,473,178; dye-woods, \$11,493; gold and silver coin and bullion, \$101,393; gums, \$4,300; hides and skins, \$97,713; india-rubber, \$131,170; indigo, \$1,328; wood (not specified), \$13,968; fruits, \$27,643; brown sugar (2,545,042 lbs.), \$114,434; others, \$57,992; total, \$3,070,339. *Imports from the U. States into Central America*.—horses, \$1,200; beer, \$4,594; blacking, \$1,546; breadstuffs (chiefly wheat flour), \$494,814; cordage, rope, etc., \$7,367; cotton goods, \$92,184; drugs, \$18,044; earthenware, \$4,621; fancy articles, \$4,701; preserved fruits, \$6,119; glassware, \$6,514; gold and silver coin, \$272,608; hats, \$2,352; stoves, \$1,449; machinery, \$93,846; edge-tools, \$5,541; lamps, \$2,055; boots and shoes, \$13,753; saddlery, \$6,152; matches, \$5,785; organs, \$1,500; mineral oil, \$20,518; gunpowder, \$5,014; paints, \$4,312; paper, \$6,224; bacon and hams, \$7,763; salted beef, \$5,821; butter, \$4,701; cheese, \$3,099; cured fish, \$4,786; lard, \$9,771; preserved meats, \$6,766; pork, \$9,538; potatoes, \$4,292; quicksilver, \$24,290; sewing-machines, \$12,535; soap, \$7,852; refined sugar, \$12,692; tallow, \$26,853; tobacco (leaf), \$3,908; tobacco (manuf.), \$7,966; steamers, \$30,000; wine, \$11,769; wood (boards, deals, etc.), \$42,573; manuf. of wood, not specified, \$12,924; household furniture, \$20,313; others, \$122,314; total, \$1,479,788.

Our trade with this favored region has increased considerably, but owing to the want of direct communication it is still far from being as extensive as it should be.

A decree has been issued by the government granting a premium of four reals per quintal (100 lbs.) of muscovado sugar exported. The cultivators of sugar in *G.* have enormous difficulties to contend against as compared with Peru or the West Indian Islands. The price of labor is so much higher than cooly labor, and the freights both on land and sea are so much heavier, that it is only by the most determined perseverance and industry that they are able to obtain a scanty recompense from their crops. A privilege has been granted for a term of five years to a company for the introduction of machines and the establishment of factories for the manipulation and perfection of manufactures from the textile plants of the country. These exist in great abundance in several of the departments, and the inhabitants have to some extent endeavored to utilize them. The concession in question is not intended to interfere with the employment of the methods now in use by the Indians and others, but rather to improve and perfect them, or, so far as the concessionists are concerned, to adopt those that may be new. The privileges received guarantee freedom from all duties on machinery and materials, and also from export duties on all fabrics, etc., which may be made and shipped abroad by them. A concession has been made to encourage the manufacture of cigars and cigarettes, after the methods employed in Cuba, and, with a view of exhibiting those methods to the public, the introduction free of duty of 50 cargoes of Havana tobacco is permitted. These different concessions are made as aids to the development of the industries of the country.—By decree of January 20, 1879, which took effect on October 1, 1879, the export duty on coffee has been reduced from \$1 to 50 cents per quintal.

A first line of railroad traversing the republic, from San José, on the Caribbean Sea, to the Pacific, is now (1879) in process of preparation. The grading through the mountain passes between Escuintla and *G.* city will be a formidable undertaking; but the

sound financial condition of the country will enable the government to secure an admirable road-bed on the most economical terms, and with the greatest possible despatch. The line is already looked forward to as one of material advantage to American shippers, particularly those sending merchandise from San Francisco, between which port and several ports of Central America there is a brisk and ever-increasing traffic. Indeed, it is affirmed that more than one Californian firm has advanced material for the construction of the road, receiving very liberal terms from the government. With the completion of the *G.* Central Railroad the sea-route between San Francisco and the Atlantic cities of the U. States would be shortened by from 1,500 to 2,000 m., and the additional advantage would be obtained of an extensive local trade which the Panama railway is powerless to favor.—A wagon road, now for a number of years in course of construction, will soon open up the interior to commercial enterprise, and place the Atlantic port of Santo Tomás within seven days of New York. This new facility, added to those of the harbor of Santo Tomás itself, will remove all difficulties hitherto impeding the extension of trade with the Atlantic shore of the republic, no small element of which would be the immediate introduction of American supplies for the mines: for the rich gold-districts watered by the Motagua River, and but two or three days' journey distant from the port, are attracting considerable attention, since the favorable report given of them by an American mining engineer, who surveyed them at the President's request. But trade with the U. States would not be limited to any particular branch. American manufactures of all kinds are in *G.* preferred to European, and the demand for them will increase with increased possibilities of transport.

**Finances.** The national finances of *G.* are in a very sound condition. For the year 1877 the revenue amounted to \$4,503,523, and the expenditure to \$4,428,298; leaving a surplus of \$75,225. The total amount of the national debt at the end of that year, was \$3,877,384.

**Banking.** The "Internal Bank of *G.*," founded on October 1, 1877, has a capital stock of \$600,000. The class of business done includes every line of banking operations, discounts, exchanges, deposits, loans on real estate or collaterals, and the issue of notes. Of these there were in circulation in July, 1879, about \$250,000 fully guaranteed. The bank has established relations with the different monetary centres of the world, and furnishes letters of credit, exchange, etc., to the public at reasonable rates. A branch bank has been established in Quezaltenango and another at Cabán.

**Money, Weights, and Measures.** The unit of money is the Dollar, or *Plaster*, of 100 *Centavos* = \$0.935.

The principal weights and measures are:—

The <i>Libra</i> .....	= 1.014 lbs. avoirdupois.
" <i>Quintal</i> .....	= 101.40 " "
" <i>Arroba</i> .....	= 25.35 " "
" <i>Fanega</i> .....	= 1½ imperial bushel.

The old weights and measures of Spain are in general use.

**Guava**, the fruit of the *Pisidium pyrifera* and *P. pomiferum*, nat. ord. Myrtaceæ, the pulp of which is made into a jelly of a peculiarly delicious flavor. This sweetmeat is imported in considerable quantities from the West Indies.

**Imp. duty:** Jelly, 50 per cent; marmalade, or paste, 35 per cent.

**Guayaquil.** See ECUADOR.

**Guaymas.** See MEXICO.

**Guayra** [La]. See VENEZUELA.

**Guddok**, a rustic violin, with three strings, used among the Russian peasantry.

**Gudgeon**, that part of a horizontal shaft or axle which turns in the collar; an iron pin fixed as a bearing in a beam or wooden shaft. One of the eyes driven into a ship's stern-post, to hang the rudder on.

**Guernsey.** See JERSEY.

**Guiana**, the name formerly given to the N.E. portion of S. America, lying between the rivers Orinoco and Amazon; but as about five sixths of this territory have been included within Brazil and Venezuela, the term is now generally applied to the remaining part, comprehending the settlements of Great Britain, Holland, and France.

#### I. BRITISH GUIANA.

This colony comprises the most westerly portion of the above territory, extending, as claimed by Great Britain, from lat. 0° 40' to 8° 40' N., and from lon. 57° to 61° W.; and including the former Dutch settlements of Berbice, Demerara, and Esse-

quibo. It is bounded N. and N. E. for nearly 350 m. by the Atlantic; W., Venezuela; S., Brazil; and E., Dutch Guiana, from which it is separated by the river Corentyn. Area about 76,000 sq. m.; of which, however, considerable portions are claimed by Brazil and Venezuela. Population in 1871, exclusive of American aborigines, 193,491 (of which 108,791 were males and 84,700 females), of whom but 1,414 were Europeans by birth; 56,517 were immigrants introduced by government from India, China, and Africa; 7,925 were natives of Madeira and the Cape de Verde Islands; and the rest mixed races. The government is vested in a governor and a "court of policy," consisting, besides that officer and his secretary, of the chief justice, attorney-general, collector of customs, and five unofficial persons selected by the college of electors.

The coast district of *G.* consists of an exceedingly rich alluvial flat, composed of strong blue clay, highly impregnated with marine and vegetable matter, the surface of which is on a level with the high water of the ocean; and when the lands are drained, banked, and cultivated, they consolidate, and become fully a foot lower, rendering necessary unremitting attention to the dams and sluices to keep out the sea. This flat extends from about 20 to 50 m. inward, terminating in a range of sand-hills, varying in height from about 50 to 150 feet. Beyond this the country consists of a high land which stretches out in undulating plains, rising at some places into eminences. Further S. ranges of hills occur, running N. W. and S. E., the most elevated, about 1,100 feet, being in lat. 5° N. About 70 m. further S., and parallel to the preceding, are the Picaraima Mountains, which, by means of the Concan chain running S. E., are connected with the Sierra Acaray, a densely wooded range forming the S. boundary of Guiana. These successive chains of hills appear to occupy an inconsiderable width, and the plains between them are of great extent.

The climate was formerly very destructive of human life, owing to the pestilential vapors arising from the marshes of the coast, but draining and cultivation have so far altered its character, that it is now deemed one of the healthiest in the W. Indies. The temperature is remarkably uniform; the average heat at Georgetown being, in the shade in summer, 86° F., while in winter it falls only to 82° or 83°. There are usually two wet seasons, a short one in January and February, and a long one commencing with June; but these, under the influence of cultivation, have been greatly altered both as to intensity and duration. The trade-winds blow steadily E. and N. E. for about nine months, changing to S. E. and S. in July, August, and September, the unhealthy season.

The vigor and luxuriance of vegetation in *G.* are equalled by few countries in the world. The number of indigenous plants is remarkable; and nearly one half of the surface is covered by large forest trees, many of which furnish excellent timber; others are used for furniture, or afford dye-wood; and not a few are valued for their fruits, chiefly the banana, pineapple, and cacao-nut. As yet only a few places on the coast, and on the banks of the rivers Essequibo, Demerara, Berbice, and Corentyn, have been cultivated. The plantations are commonly ranged in allotments, varying from about 500 to 1,000 acres each. The dwelling-houses, elevated on piles of timber, as a security against inundation, are generally close to the water-side, with a wharf opposite for the convenience of shipping produce. Cotton and coffee have nearly ceased to be cultivated, all the resources of the colony being concentrated upon the production of sugar and rum. Although the rum produced in this colony does not equal in character that of Jamaica, it yet occupies a respectable place in the market. With respect to the cultivation of the sugar-cane, by reason of the lowness of the land and the plan of drainage in use, namely, that known as the open-drain and round-bed method, the system of cultivation remains exactly as in the times of slavery, every part of the operations of culture being performed by manual labor. The timber-trade has, however, increased to a very considerable extent. The total imports for the year 1878 amounted to \$11,149,540, and the total exports to \$15,245,785.

The commerce of the U. States with British Guiana is slowly but steadily increasing. For the year 1878 the value of exports and imports was as follows: *Exports to the U. States:* Hides and skins, \$1,935; brown sugar (37,435,270 lbs.), \$2,044,395; molasses (420,371 galls.), \$83,012; rum (4,523 galls.), \$1,735; others, \$4,309; total, \$2,141,326. — *Imports from the U. States:* Acids (not specified), \$15,526; horned cattle, \$2,737; horses (165), \$24,778; mules (320), \$41,038; sheep (1,795), \$10,782; breadstuffs, \$88,275; candles, \$5,252; carriages, \$12,993; cordage, \$1,051; cotton goods, \$32,972; drugs, \$8,835; apples, \$2,093; glass ware, \$3,333; hay, \$10,981; ice, \$9,197; iron (manuf.), \$7,579; boots and shoes, \$3,908; leather of all kinds, \$12,563; matches, \$11,063; mineral oil, \$36,870; lard, \$14,341; paper, \$16,442; perfumery, \$3,519; bacon and hams, \$28,281; salted beef, \$52,133; butter, \$7,000; cheese, \$24,893; dried and pickled fish, \$7,516; lard, \$72,613; preserved meat, \$5,869; pork, \$184,632; potatoes, \$13,061; soap, \$3,103; tallow, \$5,414; tobacco (leaf), \$60,894; tobacco (manuf.), \$14,236; wood (boards, staves, etc.), \$132,709; household furniture, \$18,042; others, \$34,433; total, \$1,924,922.

The ports of the colony deserving of notice are only two. Georgetown and New Amsterdam.

*Georgetown*, the capital, is situated on the E. bank of the Demerara, a short distance from its mouth, in lat. 6° 49' N., lon. 58° 12' W. The streets are wide, and traversed by canals. Shops and stores are numerous, and European goods plentiful. The wharf can be safely approached only by small craft, on account of the declivity of the bank, and the ebbing of the tide, the rise of which on the coast is from 16 to 24 feet. Vessels not drawing more than 14 feet lead and discharge their cargoes in the middle of the stream, but those of greater draught cannot enter the river, owing to a bar at its mouth, and must, therefore, complete their loading outside. The town being the depot of the produce of the countries adjacent to the Essequibo and Demerara, its commerce is considerable. Pop. 35,000.

*New Amsterdam* lies in lat. 6° 15' N., lon. 57° 21' W., at the confluence of the river Canje with the Berbice, near the entrance of the latter into the sea, and about 57 m. E. of the Demerara. The coast here is encumbered with shallows, and the harbor, though good, is difficult of access. From this town is exported the produce of the plantations of the rivers Berbice and Corentyn. Vessels drawing 14 feet may sail about 200 m. up the Berbice. Pop. 5,000.

## II. DUTCH GUIANA, OR SCRINAM.

This colony lies between British and French *G.*, being separated from the former on the W. by the river Corentyn, and from the latter on the E. by the Maroni; on the N. it has the Atlantic, and on the S. Brazil. It lies between lat. 1° 30' and 6° N., lon. 53° 30' and 57° 30' W., being about 390 m. in length, from N. to S., and 260 in extreme breadth. Area 59,651 sq. m. Pop. 69,329, comprising 6,000 or 7,000 whites, and upwards of 50,000 negroes. In physical geography, climate, productions, etc., it differs but little from British *G.* The principal river is the Surinam, which flows N. through the centre of the territory, and falls into the Atlantic after a course of nearly 200 m. It is navigable for large ships for about 6 m. from its mouth. Along the coast and on the banks of the river are many settlements and plantations; and the higher parts of the country are occupied chiefly by the Maroons, the descendants of runaway negroes. The chief productions are sugar, rum, molasses, coffee, cacao, and cotton. Its chief trade is with Holland. Its commercial intercourse with the U. States is unimportant.

*Paramaribo*, the capital, chief port, and commercialemporium of the colony, is situated on the W. bank of the Surinam, 18 m. from its mouth, in lat. 6° 40' N., lon. 55° 25' W. It is built in the Dutch style, with wooden houses, and wide straight streets planted with orange-trees; pop. 22,500. It maintains an active intercourse with Holland.

## III. FRENCH GUIANA.

This is the smallest and most eastern division of *G.* It lies between lat. 2° and 6° N., and lon. 51° 30' and 54° 30' W., being bounded N. and N. E. by the Atlantic, E. and S. by Brazil, and W. by Dutch *G.* It is about 250 m. in length from N. to S., and varies in breadth from 100 to 150 m. Area 27,560 sq. m. Pop., exclusive of aborigines, 24,432. It has a coast-line of 200 m., extending from the Maroni to the Oyapoc. The low alluvial tract along the coast is of great fertility. The mountain chains run E. and W., and are almost wholly of granite, but do not attain a great elevation. The country is abundantly watered, and the coast lands appear to be less unhealthy than in British *G.* The vegetation of *G.* is very luxuriant, and the interior is thickly wooded with trees valuable for their timber, fruits, and dye-woods. Medicinal plants, including quassia, gentian, the castor-oil plant, and annatto, used in coloring cheese, are all abundant. The island of Cayenne, at the mouth of the Oyak, is about 30 m. in circumference, is separated from the continent by a narrow channel, and contains a penal settlement. The roadstead at the mouth of the Oyak, though small, is the best on the coast, having everywhere from 12 to 13 feet of water. The capital, Cayenne, is situated on the N. side of this island, and contains 6,500 inhabitants. The new town is well built, and has good streets; the government house is in the old town. The harbor is protected by a fort and several batteries. The colony is divided into two districts, Cayenne and Sinnamary, and 14 communes. The government is vested in a governor, a privy council, and a colonial council, composed of 16 members, elected by the colonists. The cultivated lands are estimated to be about one eightieth of the whole territory. Besides the staples of British and Dutch *G.*, its productions comprise pepper (including Cayenne, which is so called from the island of that name), cloves, cinnamon, and nutmegs. Trade is mostly with France and its colonies, and there is almost no commercial intercourse with the U. States.

**Guide**, a person who leads, instructs, or directs another in his way, path, or course. — A tool or instrument director.

**Guild**, a name given anciently to those commercial associations, or fraternities of particular trades, which were common in many of the towns

of England and Scotland, and under other names in all Europe. In their greatest prosperity these companies, more especially in London, became important bodies, in which nearly the whole community was enrolled; each had its distinct common-hall and property, and made by-laws for the regulation of its members.

**Guilder, Gulden, or Florin**, a silver coin which was current in many of the States of the Zollverein, and was worth about 42 cents, but variable. The gulden of Holland = \$0.385.

**Guinea**, a British gold coin, worth 21 shillings, and so denominated because the gold of which the first specimens were struck in the reign of Charles II. was brought from the coast of Guinea; and for a like reason it originally bore the impression of an elephant. On the introduction of the *sovereign*, first coined in 1817, the old *G.* coinage was gradually superseded, but accounts are still frequently kept in *G.* in England.

**Guinea Coast**, the name assigned to that part of the W. coast of Africa which commences at Cape Verga, in about lat. 10° N., and terminates with the Cameroon Mountains in the Gulf of Biafra. These are the limits more commonly given to what is called *G.*; by some they are greatly extended, so as to comprise the whole of the Portuguese settlements S. of the equator, under the name of Southern *G.*, while the coast N. of the equator is called Northern *G.* The physical aspect of the country, as might be inferred from the large extent we have under consideration, is very variable, but is characterized everywhere by excessive richness of natural scenery. In the region of Sierra Leone, Cape Mount, and Cape Mesurado the eye rests on bold headlands and high promontories covered with the richest tropical verdure. In the vicinity of Cape Palmas there are extended plains, slightly undulating, and covered with almost every variety of the palm and palmetto. On the coast of Drewiss the country rises into tablelands of vast extent, and apparently of great fertility. The Gold Coast presents every variety of hill and dale; and as we approach the equatorial region we are saluted by mountain scenery of unrivalled beauty and surpassing magnificence. There are no large or extended political organizations in *G.*, with the exception, perhaps, of the kingdoms of Ashanti and Dahomey, and neither of these has a greater extent of territory than the smaller states of Europe. For the most part, the people live together in independent communities, of not more than 8 or 10 villages, and with an aggregate population of from 2,000 to 25,000. In these different communities they have no written forms of law, but are generally governed by certain traditional usages that have been handed down from generation to generation. Nominally, monarchy is the only form of government acknowledged among them; but, when closely scrutinized, their systems show much more of the popular and patriarchal than of the monarchical element.

Respecting the natural products and trading capabilities of the country, the articles exported consist chiefly of ginger, gum, Guinea grains, palm-oil, ivory, a dyeing wood called camwood, and gold dust. Vessels visiting that coast take on board — at Sierra Leone, or on the coast of Malagueta, between Cape Mesurado and Cape Palmas — some black sailors, called *krumen*, who are of great use in doing the heavy work on board, and for boat service; thus saving the European seamen from exposing themselves too much to the sun's rays, etc. The services of these *krumen* are recompensed with two or three pieces of cotton cloth per month each. Their chief food is rice, which may be purchased at a very cheap rate on the coast of Malagueta; the price of a *kru* (a measure of capacity weighing about 30 lbs.), being a fathom and a half of cotton cloth, or any other article of proportionate value. On the coast of Malagueta (Grain Coast), the articles received

principally in barter are rice and millet; also ivory, palm-oil, and camwood, especially at Monrovia, the capital of Liberia. At Sierra Leone the pepper-tree (called *malagueta*) is cultivated on an extensive scale, and its fruit, — Guinea pepper, — after being dried, is purchased in large quantities by the Americans, and imported into the U. States. English muskets, gunpowder, rum, and tobacco are the principal articles of traffic on the whole of the coast as far as Onim, at the bottom of the Bight of Benin.

The principal European settlements, as the British on the Gambia, and the French on the Gaboon, consist of fortified depots at the mouths of rivers, from whence the merchants set out in boats at certain seasons, and ascend the streams as far as they are navigable; stopping at fixed stations to which the natives bring their productions to exchange for manufactures. In a few positions there are besides block-houses, wherein some black soldiers with European officers are kept for the protection of trade. Enterprise, however, is checked both by the savage habits of the natives and by the climate, which along the whole coast is highly insalubrious to European constitutions, and on the shores of *G.* is pestilential to a degree quite unknown in any other part of the world. — Besides the intercourse at the European settlements, there is a considerable floating traffic by vessels which trade along the coast, or enter some of the large rivers, where their cargoes are bartered for produce. This trade, which is of course the only kind carried on in the Gulf of *G.*, between the Gold Coast and Angola, a tract where there are no European settlements, and which includes the fertile and populous countries watered by the embouchures of the Quorra and other large rivers, appears to be nearly as extensive as that conducted at the European settlements.

**Guinea-Corn**, a name in the West Indies for several species of *Panicum*, including *P. pyramidale*, *scabrum*, and *tenellum*, cultivated for their seeds.

**Guinea-Fowl**, the *Numida meleagris*, a bird wild in the West Indies, but now domesticated in our poultry yards. The flesh is considered by many persons to equal that of the pheasant.

**Guinea-Grains**. See GRAINS OF PARADISE.

**Guinea-Grass, Guinea-Pepper**, a tall, strong forage grass, the *Panicum maximum* of Jaquin; naturalized in the West Indies and our Southern States, having been introduced from the W. coast of Africa.

**Guinea-Pig**, a small tailless quadruped, the *Cavia cobaya*, a native of S. America, which is often domesticated, and kept as a pet.

**Guipure**, an imitation of antique lace, which is durable, less expensive, and equally beautiful. It is made by cutting out the pattern from cambric, the flowers and heavy parts being made of the cambric, and the open parts of stitches closely resembling the antique lace. In France, a guipure lace, much resembling the Honiton, is made, which is very fine and white, and of a moderate price; a kind of gimp.

**Guitar**, a musical stringed instrument, larger than the violin, and played with the fingers. The modern Spanish *G.* has six strings, three being of silk, covered with silver wire, and three of catgut.

**Gulden**. See GUILDER.

**Gulf of Mexico**, a large indentation on the E. coast of N. America, washing the shores of the U. States and Mexico, measuring about 1,000 m. from E. to W., and 800 m. from N. to S.; estimated area, 800,000 sq. m. It is partly formed by the projection toward each other of the peninsulas of Florida and Yucatan, nearly in a line between which lies the island of Cuba, leaving a communication on its N. with the Atlantic, through the Florida Channel, and on its S. with the Caribbean Sea, through the Channel of Yucatan. The Gulf is free from banks, and contains only a few small rocky islands on the coast of Yucatan, with the Florida Reef near its E. extremity. The shores are low, and generally lined with flat sandy islands, not far from the land, and numerous lagoons. There are few harbors; and the rivers which fall into it are obstructed by bars at their mouth, which render them all, except the Mississippi, nearly inaccessible.

sible for vessels of large draught. A current of water entering the Gulf from the Caribbean Sea is soon divided into two portions, the one running E. along the coast of Cuba, the other W., in a curved line through the middle of the Gulf, round towards the Florida Channel, where it meets the other current, and the two united form the Gulf Stream. The temperature of the Gulf of Mexico is 86° in summer, and 6° higher than that of the ocean in the same parallel. The depth of the marine basin which holds the waters of the *G.* is, in its deepest part, about three quarters of a mile. At high tide the Pacific rises several feet above the level of the Gulf, and at low water it falls as far below it. The most remarkable phenomenon connected with this Gulf is the Gulf Stream, which enters it by the channel of Yucatan, passes around it, and flows out by the Florida channel.

**Gulf, Western Texas, and Pacific R.R.** runs from Indianola to Cuero, Tex., 66.8 m. This Co., whose offices are in Cuero, is in part formed of the old San Antonio and Gulf R.R., between Port Lavacca and Indianola. In 1877 the road was sold, subject to a mortgage debt of \$1,200,000, for \$100,000 and reorganized. *Financial statement:* Cap. stock, \$500,000; cost of construction (to March 31, 1879), \$1,919,727.08.

**Gullet**, the lower end of the horse-collar, around which pass the *chok-straps*, and the *breast-straps* which support the pole of a carriage.

**Gullet-Saw, Brier-Tooth Saw**, a saw that has a hollow cut away in front of each tooth in continuation of the face and on alternate sides of the blade.

**Gulley, Gully**, the tram-plates or rails laid for the use of tram-wagons.

**Gum.** Under this term are included several modifications of a distinct proximate principle of vegetables. To some of these the term *mucilage* is occasionally applied; and all the varieties may be referred to one or other of these species, — *G. arabic* furnishing a characteristic specimen of *G.*, and *tragacanth* of *mucilage*. In commerce the term *G.* is often incorrectly applied to the resins and gum-resins. *G.* is a thick, transparent fluid, that issues spontaneously from certain species of plants, particularly such as produce stone-fruit, as plum and cherry trees. It is very adhesive, and gradually hardens by exposure to the atmosphere. It is usually obtained in small pieces, like tears, moderately hard and somewhat brittle while cold; so that it can be reduced by pounding to a fine powder. When pure, it is colorless; but it has commonly a yellowish tinge; it is not destitute of lustre; it has no smell; its taste is insipid; its specific gravity varies from 1.3161 to 1.4317; it readily dissolves in water, but is insoluble in alcohol. *G.* is extensively used in the arts, particularly in calico-printing, to give consistence to the colors, and to hinder them from spreading. It is also used in painting, in the manufacture of ink, in medicine, etc. The only important gums in a commercial point of view are *G. arabic*, *G. senegal*, and *G. tragacanth*; but *lac* is popularly, though improperly, ranked among the gums. The term *G.* has likewise been applied to several artificial products, the chief of which is British *G. Imp.* free.

*Gum Ammoniac.* See AMMONIACUM.

*Gum Arabic* [Arab. *tolh*; Fr. *gomme Arabique*; Ger. *Arabische Gummi*; It. *gomma Arabica*], the produce of several species of trees of the genus *acacia*, growing in Arabia and in many parts of Africa. The best or true white *G.* is yielded by *Acacia verek*, the red *G. A.* by *Acacia adansonii*. *Acacia vera* also yields *G. A.* and a part of the Senegal *G.* The *G.* exudes naturally from the trunk and branches, and hardens by exposure to the air in irregularly shaped pieces, hard, brittle, and semi-transparent. When pure it is almost

colorless, or of a pale yellowish hue, being insipid, inodorous, and dissolving completely in the mouth. Sp. gr. 1.31 to 1.43. It is often mixed with *G. senegal*. East India *G. A.* is, though a useful, a spurious article, not being the produce of the *Acacia vera*, but of other species of plants. The best *G.* is either imported direct from Alexandria, Smyrna, Tripoli, Mogadore, Tangiers, etc. or at second-hand from them through Gibraltar, Malta, and other Italian ports. The price depends principally on its whiteness and solubility, increasing and diminishing from \$8.75 to \$40 or \$45 per cwt., according as the article has more or less of these qualities. — *Test.* Powdered *G. A.* is frequently adulterated with flour or farina, or with Senegal or other inferior *G.* The first may be detected by agitating a little of the powder with cold water: the pure *G.* dissolves rapidly, whilst the starch or flour falls to the bottom of the vessel. Or, a little of the powder may be mixed with boiling water, and when cold, tested with tincture of iodine: if it contains starch or flour, the paste will assume a blue color. If it contains cherry-tree *G.* or *tragacanth*, it will be only partly soluble in cold water, and the paste will be partly colored, and more or less interspersed with gelatinous clots. Much of the white *G. A.* of commerce is formed by bleaching *G. senegal* by what is called "Picciotto's process." The *G.* is dissolved in water and sulphurous acid gas passed through the solution. The liquid is afterwards boiled to expel the sulphurous acid, a little of which, however, still remains behind. To obtain the *G.* in a still whiter state, carbonate of baryta is added, and after agitation the mixture is filtered: it is afterwards shaken with gelatinous alumina, again filtered, and evaporated. The product (*bleached G.*) is very white, but lacks the peculiar toughness and adhesiveness of the best *G. A.*

*British G.* See DEXTRIN.

*Gum Senegal.* This product, which is largely exported from Portendie, Sierra Leone, and the French settlements on the Senegal, ranks next in quality to *G. arabic*, and for many purposes, as calico-printing, for instance, it answers equally well. The transparent and light-colored pieces are frequently picked out and sold as *G. arabic*.

*Gum Tragacanth, Gum Dragon*, is the gummy exudation of the *Astragalus verus*, hardened by the air. When digested in water, it swells considerably, a portion is dissolved, and the whole combines to form a thick mucilage. It is totally soluble in boiling water, when some change is supposed to take place in it; a great portion, however, afterwards separates. Sp. gr. 1.384. It is chiefly employed in calico-printing, and by shoemakers and lozenge-makers; by the latter to give toughness to the saccharine mass. — *Test.* Powdered *T.* is often adulterated with flour of starch, and not unfrequently with the commoner varieties of *G. arabic*. A mixture of pulverized *T.* and *G. arabic* forms, with water, a thinner mucilage than the same quantity of either of the *G.* alone. This fraud may be detected as follows: Make a mucilage of the suspected *G.*, and add thereto a few drops (2 or 3 to the dr.) of alcoholic tincture of guaiacum, taking care to stir it all the while. If the sample contains any *G. arabic*, the mixture, in the course of a few minutes, assumes a fine blue color, whilst it does not change color if the *G. T.* is pure. 5 per cent of *G. arabic* can be thus detected. When the quantity is very small, one to four hours may elapse before the color is developed. Starch and flour are detected in the manner noticed under *G. arabic*.

**Gum-Elastic.** See INDIA-RUBBER.

**Gum Juniper**, a concrete gum-resin obtained from the *Juniperus communis*.

**Gum-Lac.** See LAC.

**Gummer**, a tool or machine for deepening and enlarging the interdental spaces of worn saws.

**Gumming**, the treatment of a lithographic stone with a solution of gum arabic, after, or simultaneously with, the etching process, whereby the clean parts of the stone devoid of work are protected from receiving fatty matter, and thus reject the greasy ink when the roller passes over the stone. The clean surface of the stone is damped between each impression, but, without the gumming, it would not permanently resist the ink. — *E. H. Knight.*

**Gum-Resin.** The resins, as they exude from trees, are often mixed with gum, when they form *gum-resins*. These substances are in their properties intermediate to resins and gum, and are not therefore to be considered distinct vegetable principles. They are not entirely soluble in water or in alcohol, but proof spirit dissolves the greater part of them. They also readily dissolve in alkaline solutions when assisted by heat; and the acids act

upon them nearly as upon the resins. To this class belong *ammoniacum*, *gamboge*, *assafetida*, *olibanum*, *aloes*, *myrrh*, *opium*, and others.

**Gum-Wood**, the wood of a species of *Eucalyptus* obtained in Australia, shipped in logs and planks to England. It is used in ship-building and joinery.

**Gun**, a general name for explosive instruments of different sizes, consisting of a barrel of strong metal fixed in a stock or mounted on carriages. The heavy descriptions of guns, called cannon, ordnance, field-pieces, swivels, carronades, howitzers, mitrailleurs, and mortars, are described under those several heads. They usually take their distinguishing name from the weight of the ball that will fit them. The smaller and portable kinds of guns are named muskets, rifles, carbines, fowling-pieces, revolvers, etc. This article is devoted to the breech-loading small arms which are the most generally in use at the present time.

American invention and genius have been largely directed towards the production of a simple form of breech-loading small arm. Prior to 1860 there had been less than 200 patents taken out for this purpose; from 1860 to 1880 this had increased to the large number of over 800, — more than quadruple the inventions of all the rest of the world in the same direction. It may be as well to remark here that, with the single exception of the needle-gun, every arm on a breech-loading system used in Europe is of American origin, both in its principle and application; a large portion being of American manufacture. Thus, in Great Britain, the Snider, largely adopted, is an American invention, and the Martini-Henry is acknowledged to be an infringement of an American patent. Russia, Sweden, Holland, Spain, Egypt, Greece, Turkey, and Switzerland are all using American arms; and even the Prussian needle-gun and the French chassépot bid fair to be supplanted.

**Remington Breech-loading Rifle.** This American arm made its first public appearance before a board of U. States army officers convened at Springfield, Mass., in January, 1865. It was perfected in the following year, as now in use by so many nations of both hemispheres. It has an incontestable superiority to any other system, both as regards precision and strength. The mechanical characteristics of this gun are its simplicity, manifest in the small number of parts and their direct action; and its solidity and strength, due to the extraordinary size of parts, and the relation of each part to its fellows and to the whole action. At the moment of discharge the breech-piece is supported by the front part of the hammer, which forms a shoulder to receive the recoil, and the entire strain upon the axis of the breech-piece comes on that part in the rear of the forward pin, as has been demonstrated by experiments, in which the arm has been successfully fired after having the front portion of the axis of its breech-piece removed by filing. The mechanical construction of the breech-system of the Remington arm is plainly shown in Fig. 252 the upper diagram (1) exhibiting the system with breech block and hammer closed, and the other (2) with those parts open in position for loading. The constituent parts of the action are the breech-block (B) and the pin (C); main-spring (a) and screw; trigger, (c) trigger-spring (e), and screw; locking-lever (d), locking-lever spring (D), and screw; firing-pin (H) and screw. The extractor, not indicated by a letter, is seen in diagram 2, engaging in a slot in the shoulder of the breech-block. The breech-block and hammer are solid pieces of fine steel,  $\frac{1}{8}$  of an inch thick, pivoted upon pins of the same material  $\frac{1}{8}$  in diameter. These pins pass entirely through the sides of the frame, and are held in place by the button screwed on to its left exterior side. The main-spring, trigger-spring, locking-lever, and locking-lever spring are all of steel,

the springs having the simplest possible curves, and the action of the main-spring upon the hammer being direct. The function of the locking-lever is twofold, one of its offices being to lock the trigger, so that it cannot escape from its notch in the tumbler when the breech-block is opened, and a second to secure the breech-block when closed by the force, directly transmitted, of the lever-spring (D). It should be remarked that the whole of the lock-work, with the exception of the hammer, is attached to the guard-strap, which is thus by a very ingenious construction made to subserve the double purpose of guard-strap and

Fig. 252. — REMINGTON RIFLE.

lock-plate. The extractor works in a recess cut in the left interior of the chamber, and is operated by means of a projection on its lower face, which engages with the shoulder of the breech-block, so that the act of swinging back the block withdraws the empty cartridge-case by an entirely positive motion, independent of spring or indirect agent, — a mode of extraction distinguished for its simplicity, smoothness, and certainty of operation. The firing-pin works through the breech-block, as indicated by the dotted lines at H. It is forced against the primer by the sudden shock of the hammer, which is imparted through the direct action of the strong and very slightly curved main-spring, so that a miss-fire is impossible with cartridges made and fitted to the chamber. The operation of this arm is especially simple. To load the piece the hammer is first brought to full cock, and the breech-piece swung back by pressing the thumb-piece with the thumb of the right hand. The backward motion of the breech-block withdraws the discharged shell from the chamber, and if this motion is executed quickly, with the muzzle of the arm slightly elevated, the case will fall out without necessitating the use of the fingers. The fresh cartridge is then inserted, and the breech closed in the continuous motion. The arm is then ready to fire, and after very little practice a soldier can get 17 shots per minute. The fire-arms manufactory at Ilion, in Herkimer County, was originated in 1825 by Mr. Eliphalet Remington, who died in 1861. In 1864 the private firm, still including only the sons of the founder, was made into a company incorporated under the name of E. Remington and Sons. The entire stock of the company, valued at about \$3,000,000, is owned by the Remington family.

**Ward-Burton Breech-loading Rifle**, originally the invention of Mr. Bethel Burton, of Brooklyn, N. Y., has been since greatly developed and improved by Brig.-Gen. W. G. Ward. It is constructed on the bolt, or needle-gun, system, but its principles differ essentially from those of any other arm on the bolt system. It is operated by holding the piece in the left hand below the lower band, in the position known in the manual for muzzle-loading arms as *prime*, and seizing the handle of the breech with the right hand, nails uppermost. The breech is then opened by turning the handle up and with-

drawing it to its full extent of motion, a cartridge taken from the pouch with the right hand and dropped bullet-end to the front in the now open receiver, and the breech closed by reversing the motions required to open it. By the motion of opening the breech to reload, the empty cartridge-shell will be ejected. The breech, however, may be closed during the act of raising the gun to the position of aim. A manual to load and fire by command in six motions may thus be readily devised. Practically, to load and fire requires but four motions. The piece, altogether, consists of 15 pieces, which, with some addition to its cost, might be reduced to 11 pieces. This rifle has been submitted to the severest tests of rusting, has been filled with sand and dirt, and thoroughly tried with defective cartridges, without in the least affecting its perfect working. The machinery required for the manufacturing of the breech mechanism is simple, and cheaper, it is claimed, than any other known; in fact, the parts can be made with ease in any shop having a lathe and scraper. This rifle was satisfactorily tested before the New York State Board in 1867; Massachusetts State Board in 1868; the Naval Board in 1869; and in April, 1870, before the Army Board in session at St. Louis, Mo.

**Peabody Breech-loading Rifle.** The record of this arm entitles it to rank among the best productions of American industry. The inventor, Mr. Henry O. Peabody, of Boston, an active and thoughtful mechanic, had his attention first directed to the subject of breech-loading arms at the commencement of the civil war. After careful labor and study he worked out the original idea of the mechanism of the Peabody gun, which is today as he made it, unimproved and unchanged, the first and only patent in the U. States, having been taken out July 22, 1862. This gun has a falling breech-block, hinged at the rear and depressed by the guard-lever, whose short arm engages in a recess of the block and controls its movements. When the block is down the cartridge is slipped into the bore, and the piece is fired by the fall of the hammer upon a firing-pin sliding in a groove in the side of the block. In opening to reload the block drops upon an elbow-lever, and withdraws the spent cartridge-shell. The Peabody arm has been, since its origin, manufactured and controlled by the Providence Tool Company, of Rhode Island, who have a capacity sufficient to turn out 10,000 guns per month.

**Whitney Breech-loading Rifle.** Great improvements in the machinery for the manufacture of small arms are due to Eli Whitney, the celebrated inventor of the cotton-gin. His establishment for this purpose was originally started in 1798, thus making him the pioneer in this line of manufacture. He was the first to invent and develop the system known as the American or interchangeable system, carried out by the use of hardened jigs or forms of the same shape as the part to be produced, thereby turning out every piece for each particular part of the same form and dimensions. He also introduced the use of milling, by means of revolving cutters, those irregular and intricate forms necessary to be produced in making a gun. The Springfield armory was established in 1809, and the system invented by Mr. Whitney was put in force there, and has been in use in all government works ever since. The English War Department was forced to adopt the same system, and put it to practical use in 1855 by importing a large amount of American machinery. Since that date other governments have adopted the same general system, which is made specially necessary in the proper manufacture of breech-loading small arms. The admirable series of inventions used in this system remains now, like the cotton-gin, the same as when first invented, no practical change having taken place in 80 years, notwithstanding the inventive genius which has been at work during that period of time. No patents have ever been taken out for the Whitney inventions, but they have been freely given to the public, and have saved the U. States government large sums of money by lessening the cost and perfecting the manufacture and repairs of fire-arms. The Whitneyville Armory, property of the Whitney Arms Co., is now one of the largest in the U. States. It is located near New Haven, Conn., and is now under the control of the son and grandson of the founder, who have added many valuable improvements. The system of breech-loading small arms, now known as the Whitney system, has its foundation in the invention of Col. T. T. S. Laidley, of the U. States Ordnance Bureau, and was first patented in the U. States in 1896. The claims made for this arm, as remodelled and improved by the present owners, are very strong, the most prominent being as follows: The arm loads on the half cock, the breech is securely locked the instant it is closed, thereby preventing the possibility of the charge flying back and injur-

ing the person firing. When loaded, and the hammer on the safety notch, the arm cannot be discharged by any violent concussion or by the accidental pulling of the trigger. The breech-block and locking-shoulder, made of the best steel, are of such form and dimension, and are so firmly supported by solid steel pins passing through the iron frame, that the strength of the system in resisting the recoil of the charge is claimed to be equal, if not superior, to any other. There are no delicate springs or pins liable to be constantly breaking. The parts are very few as compared with other systems, and they are all simple in purpose and construction. The motions in operating the system are short and natural, and are performed with one hand. They are so simple that the common soldier needs little or no instruction, and accident from ignorance of the position of the parts is impossible. The throwing up of the breech-block pushes the cartridge into the chamber, so that the fingers need not be brought in contact with the barrel when hot. The hammer being entirely independent of the locking-shoulder, it can be brought to full cock without unlocking the breech. The cartridge shell is thrown from the barrel automatically on opening the breech to receive a new charge. The barrel can be cleaned from either end without dismounting any of the parts, and the arm dismounted and reassembled with the greatest ease by a person not a mechanic.

Other well-known forms of American breech-loading guns

Fig. 253. — THE MARTINI-HENRY RIFLE.

A, ready for loading; B, loaded and ready for firing.

are the *Springfield*, the *Joslyn-Tomes*, the *Berdan*, the *Earnest*, the *Colt*, the *Milbank*, the *Spencer*, the *Roberts*, the *Bull-Lamson*, the *Broughton*, etc.

**Martini-Henry Breech-loading Rifle.** This arm, lately adopted by the British government to replace the "Snider," or "Converted Enfield," is a combination of Henry's system of rifling with Martini's mechanism for breech-loading, which last is a manifest infringement on the American Peabody patent. The breech-block is pivoted at its upper rear portion, being moved up and down by a lever at the rear of the trigger-guard. The firing is by a spiral spring, which actuates a firing-pin. The cartridge-shell extractor works on a pivot below and behind the barrel being operated by the descent of the front end of the breech-block upon one arm of the bell-crank lever. A competent military authority, after instituting a careful comparison between the breech-loading small arms of Germany, France, and England, concludes that in the Martini-Henry the English have a weapon "giving great accuracy at long ranges, combined with a very flat trajectory, and therefore fearfully destructive at short ranges, with terrible smashing power and great penetration, not liable to fouling, easily cleaned, and not injured by being left uncleaned, with grooves which do not lead or wear out; a breech mechanism easily constructed by machinery, easily worked, not liable to get out of order, utterly unaffected by rust or dirt, wearing well, quickly loaded, light, handy, strong, and durable." As an evidence of the accuracy of fire in this rifle, it is said that of 20 shots fired at 1,200 yards, the mean absolute deflection of the hits from the centre of the group was 2.28 feet. The highest point in the trajectory at 500 yards is rather over 8 feet, so that the bullet would not pass over a cavalry soldier's head within that distance. The trajectory of the Snider at the same range rises to nearly 12 feet. The bullet will pass through from 13 to 14 1/4-inch elm planks placed 1 inch apart at 20 yards distance: the number pierced by the Snider under similar circumstances being from 7 to 9. As regards rapidity of fire, 20 rounds are said to have been fired in 53 seconds; and one arm which had been exposed to rain and water artificially applied for seven days and nights, and had during that time fired 400 rounds, was then fired, without cleaning, 20 rounds in 1 minute 3 seconds.

**Chassepot Breech-loading Rifle,** the weapon of the French Infantry. This arm has a rifled barrel, with a breech mechanism of great simplicity, which is represented in section in Fig. 254. The piece marked B corresponds to what is called the

"hammer" in the old lock used with percussion-caps, and the first operation in charging the rifle consists in drawing out B, as shown in the cut, until, by the spring, C, connected with the trigger, A, falling into a notch, the hammer, if we may so term it, is retained in that position. The effect of this movement is to draw out also a small rod attached to the hammer, and terminated in front by a needle, about  $\frac{1}{2}$  in. long, at the same time that a spiral spring surrounding the rod is compressed, the spring being fastened to the front end of the rod, and abutting against a screw-plug, which closes the hinder end of F, and permits only the rod to pass through it. The piece F, which is also movable, has projecting from its front end a little hollow cylinder, through the centre of which the needle passes, and this little cylinder has a collar, serving to retain its position, an india-rubber ring surrounding a portion of the cylinder, and forming a plug to effectually close the rear end of the barrel. It will be noticed that the cylinder is continued by a smaller projection, which forms a sheath for the point of the needle. The movable breech-piece, F, is provided with a short lever, E, by which it is worked. The second movement performed by the person who is charging the piece is to turn this lever from a horizontal to a vertical position, which thus

Fig. 254. — THE CHASSEPOT RIFLE  
(Section of the breech)

causes the piece F to turn 90° about its axis, and then by drawing the lever towards him he removes the piece F from the end of the barrel, which, thus exposed, is ready to receive the cartridge. The cartridge contains the powder and the bullet in one case, the posterior portion containing also a charge of fulminate in the centre, and it is by the needle penetrating the case of the cartridge and detonating this fulminate that the charge is exploded. When the cartridge has been placed in the barrel, the piece F is pushed forward, the metallic collar and india-rubber ring stop up the rear of the barrel, and on turning the lever, E, into a horizontal position, the breech is entirely closed. If now the trigger be drawn, the hammer is released, and the spring carries it forward, at the same time impelling the needle through the base of the cartridge-case, where it immediately causes the explosion of the fulminate. The bullet is conical, and its base having a slight enlargement, the latter moulds itself to the grooves with which the barrel is rifled. The chassepot has an effective range of 1,093 yards, and the projectile leaves the piece with a velocity of 1,345 ft. per second, the trajectory being such that at 230 yards the bullet is only 18 in. above the straight line. The piece can be charged and fired by a soldier in any position, and it was found that it could be discharged from 7 to 10 times per minute, even when aim was taken through the sights with which it is furnished, and 14 or 15 times per minute without sighting.

The Needle-Gun is the Prussian arm of which we heard so much during the last wars against Austria and France. The fundamental principle of the needle-gun lies in this: that a cartridge is employed which contains within itself the fulminating compound that is to ignite the powder; and since this fulminate lies buried between the powder and the bullet, it can only be reached and struck, and hence ignited, by a needle piercing the cartridge. First, beginning with the feature most prominent, is the needle, fixed in a holder or bolt encircled by a spiral spring, the recoil of which is to dart the needle into the explosive charge; second, the lock, or appliance for drawing the needle back to put into connection with the trigger; third, the chamber, which forms the breech-piece, and which carries a little tube, or guide, through which the needle passes to the cartridge. The whole of this mechanism is carried in a cylindrical case, which is fixed to the stock by bands, and into which the barrel is screwed, so that the case forms, as it were, a prolongation of the barrel. Lastly, there is the trigger, which, when pulled, discharges the needle from its detaining catch. The advantages claimed for the needle-gun are chiefly these: that the bullet is propelled through rifled grooves without violent forcing into the barrel, — indeed, without coming into contact with it; that the loading is sim-

ple and rapid, the ball, powder, and cap being contained in the cartridge; that the loading is from the breech; that the combustion of the powder and cartridge-case is more complete than in any other guns; that the escaping gas carries but little smoke with it; that the gun is instantly disabled, if necessary. Some of these advantages are, of course, common to most breech-loaders; but there is one especial merit in the needle-gun which is not so common to other constructions, and that is the ease with which the mechanism can be made and put together. Notwithstanding the many advantages claimed by the needle-gun, the many rifle-trials in the U. States, in Great Britain, and other countries, show that the various governments, and military men generally, have not recognized the superiority of the needle-gun, which, in fact, is already partially discarded by the German government, as is the chassepot by the French.

Gatling Gun. See MITRAILLEUR.

**Gun-Barrel**, the metallic tube of a gun.

**Gun-Boat**, a small vessel formerly fitted to carry one or two guns at the bow; but they are now very differently constructed.

**Gun-Carriage**, the framework or movable support for a piece of ordnance.

**Gun-Case**, the box or receptacle for a rifle or fowling-piece.

**Gun-Cotton**, **Pyroxylin**, an explosive preparation which, as a substitute for gunpowder, has undergone a large amount of experiment and inquiry on the part of chemists. The best method to prepare it is in mixing 89 parts by weight of nitric acid,

sp. gr. 1.424, with 104 parts by weight of sulphuric acid, sp. gr. 1.833. When the mixture has cooled down to between 50° and 60° F., clean rough cotton, in as open a state as possible, is immersed in the acid; when well soaked the excess of acid is drawn or poured off, and the cotton pressed lightly in order to separate the principal portion of the acid. The cotton is then covered over and left for half an hour, when it is pressed and thoroughly washed in running water to get rid of the free acid. After being partially dried by pressure it is washed in an alkaline solution made by dissolving 1 oz. of carbonate of potash in a gallon of water. The free acid being thus got rid of, it is put into a press, the excess of alkaline solution is expelled, and the cotton left nearly dry. It is then washed in a solution of pure nitrate of potash, 1 oz. to the gallon, and being again pressed, is dried at a temperature of from 150° to 170°. *G.-C.*, compared with common cotton, is heavier, harsher, more electric, more soluble in ether. When dissolved in ether it forms *collodion*, so much used in photography. It explodes violently at 350° to 400° F., — much more rapidly, indeed, than gunpowder, having thrice the force. Hence the supposition that *G.-C.* would be a valuable substitute for gunpowder as an explosive agent, for artillery purposes, sporting, blasting, and pyrotechny. A great drawback to the realization of this hope is the danger attending the use of the substance, due to the temperature at which it explodes, and the violence of the explosion. The making of it is very perilous, having led to several frightful calamities. Artillerymen, too, object to its suddenness of action; for the explosive force expends itself before the ball or bullet is prepared to receive the full effect. This is quite consistent with the results of experiments on gunpowder, by

which it is known that the powder may be too violent and sudden in its action for artillery purposes. *G.-C.* has another defect: it absorbs humidity very rapidly, and cannot be used till redried.

Import duty same as gunpowder.

**Gunda**, the sum of 4 cowry shells used by the poorer natives of India as a medium of currency in smaller or fractional payments and purchases.

**Gun-Flint**, a sharpened flint for a firelock: since the introduction of percussion-caps to rifles and pistols, flintlocks are now seldom used, except among a few barbarous tribes.

**Gunjah**, a name for the dried hemp-plant, which is cut after flowering, and formed into bundles from 2 to 4 feet long by 3 inches in diameter. The resinous substance contained in the plant is narcotic, causing intoxication. *G.* is chiefly sold for smoking with tobacco, and is used in Hindostan, Persia, and other parts of the East.

**Gunlock**, an apparatus for igniting the charge, which has advanced in improvement by several stages. In the earliest muskets a slow-match was applied by hand to the powder in the touch-hole. In the *matchlock* the match was brought down by a trigger and lever upon the touch-hole. In the *wheel-lock* a rotating steel wheel, coming in contact with a piece of flint, struck sparks, which kindled the powder in the touch-hole. In the *flint lock* the contact of flint and steel produced a spark in a more convenient way than in the wheel-lock. The flintlock is now superseded by the *percussion-lock*, in which a hammer gives a smart blow to a small *percussion-cap*, explodes some composition contained in it (see *PERCUSSION CAP*), and kindles the powder through a small hole in the nipple on which the cap is placed. All the famous rifles of the present day have locks peculiar to themselves. See *GUN*.

**Gun-Metal**, an alloy containing 90.5 per cent of copper and 9.5 per cent of tin, used for casting pieces of ordnance (erroneously termed "brass guns"), also those parts of machinery which are subjected to considerable friction.

**Gunnery**, the science of constructing and using large and small fire-arms.

**Gunning-Punt**, a low, flat-bottomed boat, used for shooting wild-fowl from.

**Gunny, Gunny-Bag, Gunny-Cloth**, a coarse strong sacking made in India, and much used for bags and bales for wrapping cotton, rice, spices, and other dry goods. In Bengal gunny-cloth is made of jute, the produce of species of *Corchorus*, and is exported made up into bags, or in pieces, each large enough for one bale. The gunny-bags of Bombay and Madras are, however, made up of different kinds of sunn fibre, the *Crotalaria juncea*. Considerable quantities are yearly imported into the U. States, chiefly for baling cotton.

*Imp. duty*: not cotton bagging, valued at not over 10 cts. per sq. yd., 3 cts. per lb.; valued over 10 cts. per sq. yd., 4 cts. per lb. — Suitable for same use as cotton bagging, valued at not over 7 cts. per sq. yd., 2 cts. per lb.; valued over 7 cts. per sq. yd., 3 cts. per lb. — Old or refuse, fit only to be remanufactured, free.

**Gunpowder** [Fr. *poudre*; Ger. *Pulver*, *Schiesspulver*; It. *polvere*; Sp. and Port. *polvora*], a well-known inflammable powder, is composed of nitre, sulphur, and charcoal, reduced to powder, and mixed intimately with each other. The proportion of the ingredients varies very considerably; but good *G.* may be composed of the following proportions: viz. 76 parts of nitre, 15 of charcoal, and 9 of sulphur. These ingredients are first reduced to a fine powder separately, then mixed

intimately, and formed into a thick paste with water. After this has dried a little, it is placed upon a kind of sieve full of holes, through which it is forced. By this process it is divided into grains, the size of which depends upon the size of the holes through which they have been squeezed. The powder, when dry, is put into barrels, which are made to turn round on their axes. By this motion the grains of *G.* rub against each other, their asperities are worn off, and their surfaces are made smooth. The powder is then said to be glazed. The great explosive power of *G.* renders its manufacture a dangerous one. Every precaution is taken in *G.* mills and in magazines, to avoid the use of artificial lights, and to guard against the production of sparks from metals, etc. In "sporting powders" the proportion of saltpetre is generally from 1 to 3% greater than in the government powders. In "miners' powders" it is about 10% less, an excess of sulphur being used. The following are the proportions adopted by the principal powers:—

	Saltpetre.	Charcoal.	Sulphur.
U. States.....	75	14	10
England.....	75	15	10
France.....	75	15	10
Austria.....	75	12.5	12.5
Germany.....	75	15	10
Russia.....	73.75	13.50	12.63
Spain.....	76.47	10.78	12.75
Sweden.....	76	15	9

The quality of *G.* is best estimated by actual trial of its power and cleanliness in use. It should be dry, hard, and free from dust; the grains should be of a uniform size, and glossy, and the color a dark-gray or brownish-gray, not perfectly black. A very little placed on a piece of paper and fired should instantly explode with a flash, and neither leave an appreciable residue on the paper nor burn it. Dried by the heat of boiling water, or in vacuo, it should not lose more than  $\frac{1}{2}$  to 1% of its weight. Damp powder rapidly "fouls" the gun. *G.* containing more than 7% of water does not recover its strength by simply drying it. The sp. gr. ranges between 1.795 and 1.800. The explosion of *G.* is another expression for the sudden expansion of a solid into a gas that occupies nearly 2,000 times as much space. As the gas *will* find room for itself, it expels a ball from a cannon with enormous velocity, or a bullet from a gun or pistol, or bursts open rocks in a quarry or mine, or dislocates into a thousand fragments the sunken hull of a wrecked ship, or blows up any building in which it may have been incautiously stored. In pyrotechny, *G.* is used in many modified forms, to produce brilliant colors and fiery trains, as well as loud reports. — As it is dangerous to carry *G.* from place to place, except under great precautions, means have been devised for rendering it temporarily non-explosive. It has been shown, for instance, that if finely powdered glass be mixed with it, the *G.* will not explode, even if a light be held to it. The minute particles of glass form a protective shield to each grain. The practical difficulty is, that the mixture must undergo a dangerous process of sifting before it can be restored to usable form. — *G.* is manufactured in many parts of the U. States, chiefly in Delaware, Massachusetts, and New York. It is usually packed in casks containing 25, 50, or 100 lbs. Its transport and storage are subject to very strict State, municipal, and harbor regulations, which differ in different States and cities. See *DANGEROUS GOODS*.

*Imp. duty*: valued at not over 20 cts. per lb., 6 cts. per lb. and 20 per cent; valued over 20 cts., 10 cts. per lb. and 20 per cent.

**Gunpowder Tea**, a very fine kind of green hyson tea.

**Gunshot**. "Within gunshot" is within the distance a piece of artillery will carry.

**Gunsmith**, an armorer; a maker of small fire-arms; a repairer of guns.

**Gunstock**, the wood in which the barrel of a gun is fixed, usually walnut.

**Gun-Tackle**, the blocks and pulleys of a gun-carriage affixed to the side of a ship, by which it is run in and out of the port-hole.

**Gun-Tackle Purchase**, a purchase or pulley made by two single blocks.

**Guntang**, an Indian dry measure of rather more than 15 lbs.

**Gunter's Chain**, a surveyor's measure named after the inventor. It is 66 feet, or 4 poles, in length, and consists of 100 links, each of which is joined to the adjacent one by three rings. The length of each link, including the connecting rings, is 7.92 inches. The advantage of this measure consists in the facility which it affords for numerical calculations. The English acre contains 4,840 sq. yds.; and Gunter's chain being 22 yds. in length, the square of which is 484, it follows that a square chain is exactly the tenth part of an acre. A square chain, again, contains 10,000 square links, so that 100,000 links are equal to an acre; consequently, the area of a field being estimated in square links, it is only necessary to divide the result by 100,000, or to cut off the last five figures, to obtain the area expressed in acres. — *Gunter's Line*, a logarithmic line engraved on scales, sectors, etc., serving to perform the multiplication and division of numbers instrumentally, as a table of logarithms does arithmetically. The numbers are usually drawn on two separate rulers sliding against each other. In rough calculations this line affords considerable facilities. — *Gunter's Quadrant*, a quadrant of a peculiar kind, adapted to the problems of finding the hour of the day, the sun's azimuth, and other common problems of the sphere. — *Gunter's Scale*, a large plane scale, having various lines of numbers engraved on it, by means of which questions in navigation are resolved with the aid of a pair of compasses. It is usually called the *Gunter* by seamen. On one side of the scale the natural lines (as the line of chords, the line of sines, tangents, rhombs, etc.) are placed; on the other the corresponding logarithmic ones.

**Gun-Wadding**, circular pieces of cardboard, cloth, felt, and chemically prepared substances, used to keep down the charge of ball or shot, etc., in a gun. In large guns rope wads are used.

**Gunwale**, the upper rail of a boat or vessel.

**Gurancux**, a recovered dye-stuff from spent madder.

**Gura-Nut**, a species of large red bean, with a bitter taste, growing on the West coast of Africa, much prized by the natives of the interior for its tonic properties.

**Gurlet**, a porous earthen jar for cooling water.

**Gurjun**, an oleo-resin; a thin balsam or wood oil, obtained in Burmah and the Eastern Archipelago from *Dipterocarpus levis*, and other species. It is used medicinally, and forms an excellent substitute for linseed-oil in the coarser kinds of house and ship painting. Mixed with dammar or resin, it preserves wood from the attacks of white ants.

**Gurlet**, a pickaxe used by masons, etc., having one sharp point and one cutting-edge.

**Gurries**, in mining, levels or workings.

**Gurrah**, a plain coarse Indian muslin.

**Gurt**, a gutter, or channel for water.

**Gusset**, an insertion or piece let into a fabric or garment.

**Gut**, prepared sheep's entrails (see CATGUT). — The substance made by pulling asunder a silkworm when about to spin its cocoon, and drawing the latter into a thread, which, after being dried, is very strong and is much used for fish-lines.

**Gutta-Percha**, the concrete juice of the *Isonandro gutta*, a tree growing only in the Malayan Archipelago, and of other species of the same genus. The stem of the *G.-P.* tree grows to the diameter of 5 or 6 feet, and on being notched yields a milky juice, which, after exposure to the air for some time, solidifies, forming the *G.-P.* of commerce. It arrives in this country in irregular blocks of some pounds in weight, usually containing a large portion of impurities in the form of pieces of wood, stones, and earth. To prepare this crude product for manufacturing into useful articles, the blocks are first cut into slices, and then torn into shreds. These are softened by hot water, and kneaded in a "masticator," the stones, earth, and other impurities being gradually washed away by water. After several hours the *G.-P.* is found to be kneaded into a perfectly homogeneous mass, which is rolled or drawn into sheets, bands, or tubes, as required. — *G.-P.* is a tough, inelastic substance, becoming soft and plastic at 212° F., at which temperature two pieces may be firmly welded together. It is one of the best insulators of electricity, is impervious to moisture, and resists the action of acids and alkalies to a great extent. Its best solvents are benzole, chloroform, bisulphuret of carbon, rectified mineral naphtha, and rectified oil of turpentine. All these dissolve it readily. The purified *G.-P.* of commerce consists of 75 to 828 parts of chemically pure *G.-P.*, which is insoluble in ether and alcohol, and a white and a yellow resin, soluble in boiling alcohol. — The uses of *G.-P.* are numerous and varied. No substance, perhaps with the exception of india-rubber, has been "tortured" to so many different purposes. Its perfect plasticity when warm, and its capability of receiving the most delicate impressions, render it invaluable in many cases where india-rubber would be useless. Beautiful mouldings, picture-frames, and a number of ornamental articles are made from it. To the chemist and photographer it is of great use as a material for making bottles, carboys, photographic baths, and voltaic battery cells. One of the most important uses to which it has been applied is for enclosing the metallic wires used for telegraphic purposes. Its indestructibility by water, its plasticity and high insulating power, have rendered it particularly valuable for this purpose. *G.-P.* may be rolled into thin, transparent sheets, which, being perfectly impervious to moisture, are well adapted for surgical, dental, and florists' and hatters' special uses; also for leather-cement, and for horse-shoe stuffing to prevent balling in winter. Again, a solution of *G.-P.* in chloroform forms an excellent dressing for incised wounds, and a protection for abraded surfaces, burns, etc. It is used in the same way as collodion.

*Imp. duty*: unmanufactured, or crude, free; manufactured, or in smooth sheets, 40 per cent.

**Gutter**, a channel or sewer.

**Gutter-Spout**, a spout for carrying off water from a roof.

**Guy**, a rope used to steady any weighty body while it is being hoisted or lowered; also, a tackle to confine a boom forward to prevent the sail from gibing. Guy likewise denotes a large rope extending from the head of the main-mast to that of the

foremast, to sustain the tackle used for loading and unloading the ship.

**Guz**, an Indian name for the yard or cloth measure, which varies in length in different places, from about 2 to 3 feet.

**Gybe**, a nautical term for the shifting over of the boom of a fore-and-aft sail in tacking, etc.

**Gyle**, a brewer's vat or utensil. — A name given by the vinegar-maker to the fermented wort which he uses.

**Gymnasium**, a public place, or school-yard, where feats of strength, agility, etc., are practised, such as climbing, leaping, etc.

**Gymnast**, an athlete; an instructor in exercises of the body.

**Gynahs**, gold and silver ornaments used by the natives of India.

**Gypsum**, native sulphate of lime, found diffused in other rocks, chiefly new red sandstone, in several parts of Europe, and in Nova Scotia, whence it is largely exported. Certain properties which it possesses render it valuable in the preparation of moulds and casts. When mixed with water to a pasty or fluid state, it constitutes *plaster of Paris*; and solidifying very soon afterwards, can be almost immediately removed from the mould or pattern. For making fine plaster the *G.* is broken

into small pieces, calcined in an oven, ground between stones, and sifted to a fine powder. Considerable tact is required in determining the quantity of water necessary to be added to this powder, and the mode of adding it. To prevent the plaster cast from adhering to the model or mould which gives it form, the latter is first brushed over with oil or with white of egg. Moulds are often made in plaster of Paris, whether the casts are to be of that substance or of metal, such as *stereotype*; and casts are often made of it where the moulds are of plaster, sulphur, or wax. Fine gypsum is also used as an ingredient in porcelain and best earthenware. The coarser specimens are kiln-burnt, and mixed with water into builders' cement for walls, floors, etc. Some of the harder kinds of gypsum are noticed under *ALABASTER*.

**Gyroscope**, an instrument for illustrating the tendency of a revolving body to maintain its rotation in a fixed plane when free from the influence of disturbing forces, and which, towards the middle of this century, attracted for some time much attention on account of its supposed capability of rendering visible the rotation of the earth on its axis.

**Gyves**, fetters or shackles for the legs.

## H

**Haaf-Boat**, a deep-sea fishing-boat in Scotland, probably a corruption of half-decked boat.

**Habbie**, a Syrian dry measure; 100 habbies of Jaffa being equal to 39 quarters.

**Habeck**, a clothier's tool, used in dressing cloth.

**Haberdasher**, a term seldom used in this country, but generally applied in England to dealers in small wares, such as sewing-threads, laces and tapes, fringes and twists, buttons, hooks and eyes, trimmings, etc. It is often combined with the woollen-drapery trade. Haberdasheries formerly included numerous articles now dealt in by other trades, as hats, clothes, glasses, spoons, etc.

**Haberdine**, a dried salted codfish.

**Habillement** [Fr.], garments, clothing, gear.

**Habit-Maker**, a tailor who makes long cloth riding-coats, or dresses for ladies, termed habits.

**Habit-Shirt**, a thin muslin or lace garment, worn over the breast and neck by females.

**Hacienda**, the Spanish name for a farm or plantation.

**Hack**, a worn-out horse. — A frame suspended from the roof for drying cheeses. — The wooden bars in the tailrace of a mill. — A framework for drying fish. — A dung-fork. — A large pick used in working stone. — In Scotland, a fodder for cattle. — A tool for cutting jags or channels in trees for the purpose of bleeding them. — To use much. — To hew or cut.

**Hackberry**, the *Celtis occidentalis*, an ornamental tree of the U. States; of medium size. The wood is hard, close-grained, and elastic, and makes the best of hoops, whipstocks, and thills for carriages. The Indians formerly made great use of it for their bows.

**Hackbrett**, the German name for the dulcimer.

**Hackery**, an Indian bullock-cart, capable of carrying a load of about 12 maunds, or from 900 to 1,000 lbs.

**Hackle, Heckle, Hatchel**, an instrument with teeth, or a board set with sharp steel spikes, for combing hemp or flax, and separating the *tow* or *hands* from the finer fibre (see FLAX). — A fly for angling, dressed merely with a cock's feather.

**Hackles**, the long shining feathers from the cock's neck, used to make artificial flies.

**Hackmatack**, a name for the timber of the tamarack, or American larch (*Larix Americana*), a useful building wood, much used in ship-building in the Eastern States.

**Hackney-Coach**, an English term for a public carriage plying in the streets for hire; now almost obsolete, from the general introduction of cabs and omnibuses. *H.-C.* are of French origin. In France, a strong kind of cob-horse (*haquenée*) was let out on hire for short journeys; these were latterly harnessed, to accommodate several wayfarers at once, to a plain vehicle, called *coche-à-haquenée*, — hence the name.

**Haddock**, a small species of codfish, the *Morhua uglefinius*, which is very abundant along our eastern coasts from New York to the Arctic regions. It is less esteemed and much cheaper than the cod; its flesh is, however, sweet and wholesome, and as it comes at the season when cod is scarce, it is a fish of considerable value. It is caught, cured, packed, and sold as the cod.

**Hadeed**, a cloth measure in Turkey, of about 34 inches.

**Haft**, the handle of a tool or knife. The manu-

facture of hafts or handles for cutlery is a vast branch of industry, employing large numbers of men, and necessitating the use of a singularly wide range of substances. Soft wood, hard wood, ebony, lignum-vitæ, vulcanized india-rubber, ivory, bone, hoof, horn, pearl, shell, tortoise-shell, iron, brass, gold, silver, — all are employed, and many other substances besides, either singly or in combination. To bring these substances into shape, almost every mechanical process known in the arts is employed, — sawing, planing, turning, carving, stamping, forging, casting, embossing, inlaying, plating, electro-plating, grinding, polishing, engraving, etc., according to the value, form, and size of each handle. Some handles are made by riveting flat pieces of bone, etc., upon a flat iron continuation of the blade; some by the *through-fung*, an iron prong projecting from the blade, fitted into a hole drilled right through the handle, and riveted at the end; some by a shorter prong fixed into a shorter hole by resin solder; and some by weighting the interior of the handle with a little lead, to give the *balance* action to the blade.

**Haft-and-Scale Cutter**, one who shapes, cuts, or presses, bone and horn handles, for cutting instruments.

**Haggis-Bag**, the maw of a sheep, used to make a haggis in. The haggis, a national dish in Scotland, is a baked mess of sheep's entrails, thickened with oatmeal and seasoned.

**Haggle**, to be tedious in making a bargain; to be long in fixing a price; to hesitate; to cavil.

**Hague (The)**. See HOLLAND.

**Haik**, a woollen or cotton cloth worn by Arabs over the tunic, but under the burnouse.

**Hail**, to speak aloud or call to another.

**Hailoh**, a long measure at Sumatra, equal to 4 feet.

**Haim** [Fr.], a fish-hook.

**Hainan**. (See CHINA.)

**Hair** [Fr. *cheveu*; Ger. *Haar*, *Menschen-haar*; It. *capello umano*; Sp. *cabello*]. Human *H.* makes a very considerable article in commerce, especially since the mode of perukes and chignons has obtained. Good *H.* is well fed, and neither too coarse nor too slender; the bigness rendering it less susceptible of the artificial curl, and disposing it rather to frizzle; and the smallness making its curl of too short duration. Its length should be about 25 inches; the more it falls short of this the less value it bears. A head of girl's *H.*, as usually imported, weighs from 1½ to 1¾ lbs. The lighter colored *H.*, which bears the highest value, is the production of Germany; the darker shades are imported from Belgium, France, Italy, and Spain. The value of *H.* changes with the fashion, which is subject to violent fluctuations; the price has been known to range from \$1 to as much as \$20 per lb., especially when golden tresses were in favor, seeing that golden *H.* is comparatively a rarity.

**Hair of Beasts** [Fr. *poil*, *crin*; Ger. *Haar*, *Hu-haar*; It. and Sp. *pelo*]. In its mechanical nature *H.* may be regarded as a condensed form of cuticle. The feathers of birds may be considered as analogous to *H.*, while the only two classes of animals that are wholly devoid of any kind of *H.* are the fishes and reptiles. The variety in the conformation of *H.* is very great, ranging from the finest wool to the quills of the porcupine or the horn of the rhinoceros, which last is nothing

more than an assemblage of many hairs in one compact mass.

**Hair Manufacture.** The various uses to which *H.* is applied are familiar to every one. The most valuable kind is human *H.* The making of wigs, perukes, beards, whiskers, mustaches, eyebrows, fronts, chignons, etc., constitutes a trade in itself, in which many ingenious processes are involved. Belonging to what may be called the chemistry of the trade is the preparation of *H. dyes, H. washes, H. pomades, and H. powders.* How far the artist succeeds in increasing the beauty of human *H.* by these additions is a matter of fashion and individual taste; but the amount of trade done in this way is very large — *Horsehair.* To prepare it for manufacturers, horsehair is classified into *best, seconds, black, gray, soft, hard, curling, spinning, weaving,* etc. To prepare the *curled H.* for stuffing cushions, etc., short horsehair is carded between teeth or combs, *tipped or beaten* in a heap with a cane, *curled* into a kind of large rope, *steeped* in cold water, *heated* in an oven, *opened* by partial uncurling in an opposite direction, and *twisted* or picked into curling pieces, which acquire a remarkable springy quality. Short white *H.* is used for brushes. *H.* of medium length is spun into clothes-lines, and woven into filtering-bags, etc. The long *H.*, by processes of *heckling, carding,* etc., is woven up into *horsehair cloth*, for sofa coverings, and so forth, which has a black, flaxen warp with a horsehair weft, each weft thread consisting of a single *H.* According to the length of the *H.*, so can this cloth be made of widths varying from 14 to 40 inches. Long white *H.* are used for violin bows and fishing-lines. At some of the industrial exhibitions there have been displayed, from Russia, bowls, dishes, and plates made of hare and rabbit *H.*, felted into a tough layer, and varnished; they had something the appearance of papier-mâché. These, however, were examples rather of fur-work than of *H.*-work. For various purposes in the arts, the *H.* of the camel, fitch, sable, hog, cow, badger, goat, dog, and other animals is used.

**Imp. duty:** *H.* of all kinds, cleansed or uncleaned, but not manufactured, not otherwise provided for, 10 per cent. All manufactures of *H.*, not otherwise provided for, 30 per cent. Bracelets, braids, chains, curls, and ringlets of *H.* or partly of *H.*, 35 per cent. Hogs' *H.*, 1 ct. per lb. Hogs' *H.*, curled, for beds and mattresses, and not fit for bristles, free. Horse and cattle *H.*, cleaned or not, drawn or not, but unmanuf. free. Horse *H.*, long for weaving, cleaned or not, free. Human *H.*, cleaned or drawn, or prepared for use, but not manuf., 30 per cent. Human *H.*, manuf., 40 per cent. Human *H.*, raw, uncleaned, and not drawn, 20 per cent. See also BRISTLES, HAIR-CLOTH, HAIR, NET, WOOL, etc.

**Hair-Breadth.** a nominal measure of length, the 48th part of an inch.

**Hair-Broom.** a long-handled sweeping-broom for servants.

**Hair-Brush.** a toilet-brush for smoothing and dressing the hair.

**Hair-Cloth.** a woven fabric of horsehair. The hair used for weaving consists of the long hair from horses' tails. It is procured principally from South America and from Russia. All the black and gray hair is dyed for the manufacture of black *H.-C.* for covering furniture. The white is reserved for dyeing of the brighter hues, such as green, claret, crimson, etc. The quality of the cloth, as well as the brilliancy and permanency of the colors depends in a great degree on the nature of the warp, which may be either of cotton, linen, or worsted. In the manufacture of *H.-C.*, either plain or damasked, the weaver uses a sort of hook-shuttle, which he passes between the threads of the warp, or shed, towards his left hand; the assistant, or "server," places a single hair over the end of the hook, and the weaver draws it through the warp. The placing of the hairs one by one renders this a tedious operation, and one that does not admit of the application of machinery, which is so advantageously employed in fabrics where the shot or weft consists of a continuous thread. An imitation of *H.-C.* is made by the use of hard-twisted and highly gummed and polished cotton threads.

**Imp. duty:** *H.-C.* known as hair-seating, 18 inches wide or over, 40 cts. per sq. yard; the same, less than 18 inches wide, 30 cts. per sq. yard; *H.-C.*, not otherwise provided for, 30 per cent.

**Hair-Cord.** a cotton goods, the warp of which consists of corded ribs.

**Hair Cosmetics.** under this head are included all preparations which are used for beautifying, preserving, or restoring the hair. These are described in different parts of this work, and we shall here merely name the principal heads under which they will be found. The hard pomatum used for keeping the hair, mustache, and whiskers in form, and sometimes to color them at the same time, is noticed under *Cosmétique*; the mucilaginous preparation for stiffening the hair, under *BANDOLINE*; the compounds for removing superfluous hairs, under *DEPILATORY*; the applications for the cure and prevention of baldness, under *POMADE* and *WASH*; and those employed to cleanse or beautify the hair under the last two heads, and under *HAIR-DYE* and *OIL*.

**Hair-Dresser.** an artist who trims and arranges the hair; a barber, who often combines the sale of perfumery and toilet articles.

**Hair-Dye.** The practice of dyeing the hair is of great antiquity; and though not so common as formerly, it is still far from infrequent at the present day. The numerous preparations vended for this purpose have generally a basis of lead or silver. Bismuth, pyrogallie acid, and certain astringent vegetable juices are also occasionally thus employed. The following list embraces about all those of any value:—

1. Litharge, 1 part; fresh-slaked lime and starch, of each 2 parts; all in fine powder, and perfectly dry; mix, and keep the compound in well-corked bottles. This powder is to be made into a thin paste or cream with water (for black) or milk (for brown), and applied to the hair (previously freed from grease with soap and water, and dried) by means of a sponge or brush, or the fingers; observing to rub it well into the roots, and to pass a comb for some time through it, to insure its coming in contact with every part. The whole must be then covered with a moist leaf of cotton wadding, or some brown paper several times doubled and well damped with hot water, and allowed to remain so for 3 or 4 hours, or even longer; or an oil-silk cap, or a bladder, may be worn, the object being simply to prevent the evaporation of the moisture. After a sufficient time has elapsed the powder may be removed by rubbing it off with the fingers, and afterwards washing it out with warm soap-and-water. A little pomatum or hair-oil will restore the usual gloss to the hair. Another method of operating is to apply the cream or paste as before, and then to keep rubbing it about the hair with a brush as long as may be required, occasionally adding a few drops of hot water to preserve the whole moist. In this way the action of the dye is facilitated, and the process concluded in a much shorter time.—2. Lime (slaked in the air), 2 parts; carbonate of lead (pure white lead), 1 part; mixed and applied as the last.—3. (*Aqua Orientalis.*) From grain silver, 2 dr.; steel filings, 4 dr.; nitric acid, 1 oz.; soft water, 1½ fl. oz.; digested together, the solution being afterwards diluted with water, 3½ fl. oz., and filtered. Applied by means of a fine-toothed comb, or a half worn tooth-brush, to the hair, previously well cleaned with soap and water, and dried.—4. (*Hair Restorer.*) This is in reality a dye. Sulphur, 45 gr.; acetate of lead, 20 gr.; glycerine ½ oz.; water to make up 10 oz.—5. (*Golden Hair-dye Auroline.*) A solution of peroxide of hydrogen in water, containing from 3 to 6 per cent of the peroxide.—6. (*Brown Hair-dye.*) Acetate of lead, 2 dr.; hyposulphate of soda, 1 dr.; rose-water, 14 oz.; glycerine, 2 oz. Dissolve the acetate of lead and the hyposulphate in separate portions of the rose-water; filter separately, mix the solutions, and add the glycerine.—7. (*A harmless hair-dye.*) Ten parts of subnitrate of bismuth and 150 parts of glycerine are mixed in a glass vessel and heated in a water bath; solution of potash is then added in small portions, and with continued agitation, until a clear solution has been obtained, to which a concentrated solution of citric acid is added until merely a slight alkaline reaction is observed. Enough orange-flower water is added to make the whole liquid weigh 300 parts: the addition of a small quantity of a solution of an aniline color completes the preparation.—8. Fresh-slaked lime, 5 dr.; water, 1½ oz.; mix, strain through gauze, and pour the milk into a four-ounce bottle. Next dissolve sugar of lead, 5 dr., in water, 3 fl. oz.; add to this solution dry slaked lime, 1 dr., stir well together, wash the precipitate with a little soft water, drain off the water, then add it to the milk of lime in the bottle, and shake the whole well together, and again before use. Applied as No. 1; but it acts much more quickly.—9. (*Tincture of*

*Walnut.*) A strong tincture of the shells of green walnuts, scented with oil of lavender. — 10. Litharge, fresh-slaked lime, and bicarbonate of potassa, mixed in various proportions, according to the shade of color desired. Used like No. 1.

**Hair Gloves**, horsehair gloves used for rubbing the skin in bathing, etc.

**Hair-Line**, a horsehair fishing line.

**Hair-Net**, a net for enclosing a lady's hair.

**Hair-Oil**, scented oil for moistening the hair.

**Hair-Pencils**, small brushes used by artists made of the fine hairs of the marten, badger, polecat, etc., mounted in quills or white iron tubes. See **BRUSH**.

**Hair-Pin**, a double pin or bent wire for confining a lady's hair. — Also a *corking-pin*, or pin used in fastening up the hair.

**Hair-Powder**, a fine powder, generally made from starch pulverized, and sometimes perfumed. It was much used in the 18th century for sprinkling upon the hair of the head, or upon the wig. It is still worn by footmen in England.

**Hair Seating**, woven horsehair, used for covering chairs, couches, and cushions.

**Hair Sieve**, a sieve or strainer with a woven horsehair bottom.

**Hair-Worker**, a fancy workman in hair, who makes ornaments for wear; bracelets, lockets, pictures, etc., in human hair.

**Hake**, a shed for drying draining tiles. — A large fish, the *Merluccius vulgaris*, frequently found three feet in length; common in the Atlantic seas and the Mediterranean. It is split and dry-cured like cod, and often passes under the name of stock-fish.

**Hakeem**, an Eastern physician.

**Haken**, a wooden frame-harrow without teeth, used in parts of Belgium.

**Halberd**, a military spear or pole-axe. — The cross-bar on a horseshoe.

**Half**, a moiety; one part of a thing which is divided into two equal parts, commercially expressed by vulgar or decimal fractions, as  $\frac{1}{2}$  or  $\frac{1}{20}$  or 0.50.

**Halfa**. See **ALFA**.

**Half-and-Half**, a mixture of beer or porter and ale.

**Half-Binding**, a style of book-binding in which the backs and corners are of leather and the sides of paper or muslin.

**Half-Boarder**, a day-boarder at a school; a scholar not permanently resident.

**Half-Bred**, a mongrel. — A race-horse not pure-blooded. — A coursing dog not completely trained.

**Half-Bushel**. See **BUSHEL**.

**Half-Cent**, a copper coin of the U. States, of the value of 5 mills. 7,985,343 pieces were coined down to 1857, when the coinage of the half-cent was discontinued; very few now remain in circulation.

**Half-Dime**, none has been coined since 1851. See **DIME**.

**Half-Dollar**. See **DOLLAR**.

**Half-Eagle**. See **EAGLE**.

**Half-Farthing**, a British copper coin, the 8th part of a penny, worth about  $\frac{1}{4}$  of a cent.

**Half-Hose**, stockings which reach only about half-way to the knee.

**Half-Hundred**, a weight of 56 lbs.

**Half-Imperial**, a kind of mill-board  $23\frac{1}{4}$  by  $16\frac{1}{4}$  inches; the whole imperial is 32 by 22 $\frac{1}{4}$ .

**Half-Moon Knife**, a double-handled and crescent-shaped knife used by the dresser of skins for parchment.

**Half-Ounce**, the moiety of the ounce, which in avoirdupois is 218 $\frac{1}{2}$  grains; in troy weight, 240 grains.

**Half-Pay**, a moiety of the usual pay.

**Half-Penny**, a piece of two farthings, the second in value of the British current copper coins, weighing 146 grains; 48 weigh a pound avoirdupois. It is worth about one cent.

**Half-Pike**, a boarding-pike used in ships.

**Half-Pint**, a measure of two gills, the fourth part of a quart, and = 17.3206 cubic inches.

**Half-Pound**, 6 ounces troy, or 8 ounces avoirdupois.

**Half-Price**, half the cost; in trade, much under the current price.

**Half-Royal**, a kind of mill-board, of which there are two sizes, small  $20\frac{1}{4}$  by 13 inches, and large 21 by 14; large whole royal is  $26\frac{1}{4}$  by  $20\frac{1}{4}$ ; long royal is 34 by 21, double royal, 46 by 21.

**Half-Sovereign**, the second in value of the British current gold coins, weighing 2 dwts. 13.63724 grains, and worth 10s. (\$2.4334).

**Half-Stuff**, in manufactures, any thing half-formed; the name for a partially prepared pulp for paper-making.

**Half-Way**, midway; equidistant from the extremes.

**Hali**, a weight used in Malacca, about 32 lbs. avoirdupois.

**Halibut**, a large flat fish of the flounder family, the *Hippoglossus vulgaris*, which often reaches the weight of 300 lbs. or more. They are caught in large numbers off the coast of New England. The flesh is dry and coarse. It is lightly salted and smoked, in which state it forms an important article of commerce. It is also cut into slices and pickled in barrels, selling at about half the price of the best herring. The fins and flaps are esteemed delicious.

**Hakodate**, or **Hakodadi**. See **JAPAN**.

**Halifax**, a seaport and city of the Dominion of Canada, the capital of Nova Scotia, on the S. E. coast of that province, lat.  $44^{\circ} 36' N.$ , lon.  $63^{\circ} 28' W.$  It is situated on a peninsula on the W. side of Chebucto Bay, and has one of the finest harbors in America. The best mark in sailing for *H.* is Sambro Light-house, on a small island off the cape of the same name, on the W. side of the entrance to the harbor, in lat.  $44^{\circ} 30'$ , lon.  $63^{\circ} 32'$ . The light, which is fixed, is 210 feet above the level of the sea; and a detachment of artillery, with two 24-pounders, is upon duty at the light-house, firing at regular intervals during the continuance of the dense fogs with which this part of the coast is very much infested. The course into the harbor for large ships after passing Sambro Light is between the mainland on the W. and Macnab's Island on the E. On a spit projecting from the latter a light-house has recently been constructed; and when this is seen ships may run in without fear. The harbor is defended by several strong forts. Ships usually anchor abreast of the town, where the harbor is rather more than 1 mile in width. After gradually narrowing to about  $\frac{1}{2}$  that width, it suddenly expands into a noble sheet of water, called Bedford Basin, completely landlocked, with deep water throughout, and capable of accommodating the whole navy of Great Britain. The harbor is accessible at all times, and is rarely impeded by ice. There is an extensive royal dock-yard at *H.*, which during war is an important naval station, being particularly well calculated for the shelter, repair, and outfit of the fleets cruising on the American coast and in the West Indies. A canal connects *H.* harbor with Cobequid Bay and the Bay of Fundy. Since its first settlement, in 1749, *H.* has continued to be the seat of a profitable fishery; and its general com-

merce is highly prosperous, engrossing as it does nearly the whole foreign trade of Nova Scotia. In 1817 *H.* was declared a free port to a certain extent, and has since acquired the privilege of warehousing. Some ships of large size are employed in the South-Sea fishery, but, generally speaking, the inhabitants are less enterprising and successful fishers than the New-Englanders. Mail-steamers sail between *H.* and Liverpool and Falmouth, England, and other packets regularly to Boston, New York, and the W. Indies. Pop. 29,582.

**Halle**, a French market-place.

**Halhard**. See HALYARDS.

**Hallier**, a birding-net.

**Hall-Mark**, in England, the official stamps, affixed by the Goldsmiths' Company and the assay officer of particular districts, to articles of gold and silver, as a test of their legal quality. The hall-mark of Birmingham is an anchor; of Chester, three wheat-sheaves or a dagger; Dublin, a harp, or figure of Britannia; Edinburgh, a thistle, or castle and lion; Exeter, a castle with two wings; Glasgow, a tree and a salmon with a ring in its mouth; London, a leopard's head; Newcastle-on-Tyne, three castles; Sheffield, a crown; York, five lions and a cross. The date mark is a letter of the alphabet, which is changed every year, and differs in different companies. See STANDARD MARK.

**Hallotype**, same as Hellenotype.

**Halometer**, an instrument for measuring the forms and angles of salts and crystals.

**Haloscope**, an optical instrument invented by A. Bravais, for exhibiting the phenomena of halos, parhelia, etc.

Fig. 255. — HALTER.

**Halter**, a rope or strap and headstall (Fig. 255) for leading or securing a horse. — A rope for hanging malefactors.

**Halvans**, impure ores, which require to be washed and freed from impurities.

**Halve**, to divide or share into equal portions.

**Halve-Net**, in Scotland, a fixed bag-net, placed within water-mark, to prevent fish returning with the tide.

**Halyards**, ropes or tackles used for hoisting or lowering yards and sails on their respective masts.

**Ham and Bacon**. The former is made from the hind legs of the pig, the latter from its sides and belly. The process of curing may be effected indifferently by the employment of salt or sugar,

or both; but the first is by far the most commonly used. After being impregnated with salt or sugar, and allowed to remain a certain time in the solution, the hams and bacon are taken out, dried and smoked. In Chicago, Cincinnati, Louisville, Baltimore, New York, etc., large quantities of bacon and hams are put up yearly for domestic use and export. Bacon is packed and shipped in boxes. Hams are commonly packed in tierces, the number of hams in the tierce and the total weight being marked on the end. In Philadelphia, Baltimore, and the Southern States all smoked pork, including hams, are termed bacon, and the classification most generally adopted is Cumberland middles, which takes in the whole side from ham and shoulder; long clear middles; and short clear middles. Roaming over the mountains of West Virginia there is a small variety of the hog, whose hams are celebrated for the excellence of their flavor. The most celebrated hams in Europe are those of Westphalia in Prussia, of York in England, and of Bayonne in France. Bacon and hams are one of the most important articles of commerce in the U. States. The exports, which for the past years have been steadily increasing, amounted for the year 1878 to the enormous total of 592,814,351 lbs., valued at \$51,752,068. See HOG.

**Hamals**, porters in Constantinople who carry immense weights between them, suspended on poles supported on their shoulders.

**Hamburg**, a small but commercially important state of N. W. Germany, the territories of which comprise the free city of Hamburg and the country immediately surrounding it, some islands in the Elbe, and several small detached districts enclosed by the duchy of Holstein. The little state is bounded on all sides by Holstein, except on the S. and S. W., where the Elbe separates it from Hanover. Area, 148 sq. m. Besides the Elbe, it is watered by the Alster and Bille. It is generally a level plain, not particularly fertile, except in the Vierländer district, to the S. E. A good deal of land is devoted to fruit, flowers, and vegetable gardens, and the entire country round the city of Hamburg is dotted over with flourishing villages and plantations. According to the terms of the constitution of September 28, 1860, the government (*Staatsgewalt*) is intrusted, in common, to two Chambers of Representatives, the Senate and the Bürgerschaft, or house of Burgesses. The Senate, which exercises chiefly, but not entirely, the executive power, is composed of 18 members. Its members are elected for life by the House of Burgesses. A first and second burgomaster, chosen annually in secret ballot, preside over the meetings of the Senate. No burgomaster can be in office longer than two years; and no member of the Senate is allowed to hold any public office whatever. The House of Burgesses consists of 192 members, 84 of whom are elected in secret ballot by the votes of all tax-paying citizens. Of the remaining 108 members, 48 are chosen, also by ballot, by the owners of house property in the city valued at 3,000 marks, or \$935, over and above the amount for which they are taxed; while the other 60 members are deputed by various guilds, corporations, and courts of justice. All the members of the House of Burgesses are chosen for six years, in such a manner that every three years new elections take place for one half the number. The House of Burgesses is represented, in permanence, by a Bürger-Ausschuss, or Committee of the House, consisting of 20 deputies. It is the special duty of the committee to watch the proceedings of the Senate, and the general execution of the arti-

cles of the constitution, including the laws voted by the House of Burgesses. In all matters of legislation, except taxation, the Senate has a veto; and, in case of a constitutional conflict, recourse is had to an assembly of arbitrators, chosen in equal parts from the Senate and the House of Burgesses. The revenue of the State, amounting to about \$6,000,000, is mainly derived from an income-tax, the amount of which upon each contrib-

2 battalions of Prussian soldiers, forming the garrison of *H.*) was as follows:—

	Inhabitants.
City of Hamburg with suburbs.....	345,801
Rural districts and Bergedorf.....	35,888
Cuxhaven and Lützebüttel.....	6,929
Total.....	388,618

**Hamburg**, the principal commercial city, emporium, and seaport of Germany, cap. of above state, and the principal of the three existing Hanse Towns and former imperial cities of that country, is situated on the N. bank of the Elbe, at the point where it receives the Alster, about 70 m. S. E. from its mouth, 60 N. E. of Bremen, and 36 m. S. W. of Lubeck; lat. 53° 32' 51" N., lon. 9° 58' 37" E. The city is oval-shaped, is about 4 m. in circuit, and was formerly fortified, but its ramparts now serve as public walks. The principal ornament of *H.* is the Alster. This river rises in Holstein, some miles above the city, and spreads out into a wide lake, which flows through deep broad ditches, some of which encircle the ramparts, while others intersect the city in all directions, forming numerous canals navigable for barges of considerable size. This lake is called the *Outer Alster*. The *Inner Alster* is a large square sheet of water, connected with the former by a narrow channel, spanned by a single arch. On three sides of the Inner Alster there are broad walks, with rows of trees, the favorite resort of the Hamburgers of all classes and all ages. The best houses in the city are to be found in its immediate neighborhood. The Jungfernstieg occupies its S. and W. sides. The whole of *H.* has been very nearly rebuilt since the disastrous fire of 1842, which raged for 3 days, and destroyed a large portion of the city. The Elbe, which may be navigated by lighters as far as Melnik, in Bohemia, renders *H.* the entrepôt of a vast extent of country. Advantage, too, has been taken of natural facilities that extend still further her internal navigation; a water communication having been established, by means of the Spree and of artificial cuts and sluices, between the Elbe and the Oder, and between the latter and the Vistula; so that a considerable part of the produce of Silesia, destined for foreign markets, and some even of that of Poland, is conveyed to *H.* There is, also, a communication by means of the Steknitz Canal with the Trave, and consequently, with Lubeck and the Baltic. And she is connected by means of railways with Berlin, Hanover, Brunswick, Kiel, etc. Direct communication with the U. States is kept up by a most excellent line of splendid steamers, running weekly between *H.* and New York. Vessels drawing 14 feet water come up to the town at all times; and vessels drawing 18 feet may come safely up with the spring tides. The largest vessels sometimes load from and unload into lighters at Cuxhaven. The trade of *H.* embraces every article that Germany either sells to or buys from foreigners. The imports consist principally of cotton, wool, stuffs, and yarn; wool, woollen, and worsted goods; coffee, which is the favorite article for speculative purchases; sugar, silk, and silk goods; tobacco, hides, iron, and hardware; indigo, wine, brandy, rum, dye-woods, tea, pepper, etc.; very large quantities of coal are imported from England. Being brought from many different places, there is a great variety of quality in the grain found at *H.*; but a large proportion of the wheat is inferior. Some of the barley is very good, and fit for malting. The oats are feed of various qualities. With the exception of coal, the exports consist of the same articles as the imports, *H.* not being a centre of consumption, but of distribution. In addition to colonial produce, British manufactured goods and grain of all sorts, they include wool, clover-seed, bark, spelter, cattle, butter, salted provisions, rags, wooden clocks, and toys, linens, and all sorts of German manufactured goods, Rhenish wines, etc. Most sorts of Baltic articles, such as grain, flax, iron, pitch and tar, wax, etc., may generally be bought as cheap at *H.*, allowing for difference of freight, as in the ports whence they were originally brought. The commerce of *H.* with the U. States, which is very important, is included in the general commerce of Germany (see GERMANY).

The total number of vessels which entered the port of *H.* in 1878 was 5,473, with an aggregate tonnage of 2,233,929. The total number of sea-going vessels (*Seeschiffe*) which belonged to the port on Jan. 1, 1880, was 104 steamers and 381 sailing vessels, with an aggregate tonnage of 227,816. The mercantile navy of *H.* is more than eight times as large as that of the kingdom of Belgium, and nearly double, in tonnage, of that of Denmark and Belgium together.

**Banking.** The *Bank of H.*, or *Giro*, was established in 1619 on the model of that of Amsterdam. It is purely a deposit bank for the transfer of sums from the account of one individual to that of another. It receives no deposits in coin, but only in bullion of a certain degree of fineness, charging one per mille for its expenses. It advances money on jewels to three fourths of their value. The city is answerable for all pledges deposited with the bank; they may be sold by auction if they remain one year and six weeks without any interest being paid. If the value be not claimed within three years, it is forfeited to the poor. This bank is universally admitted to be very well managed. There are besides in *H.* several joint-stock banks, the most important of which are the *North Ger-*

Fig. 256. — JEWS' STREET, HAMBURG.

utor is left to self-assessment. Disbursements for public works, including the maintenance of free and unobstructed navigation of the river Elbe, the jurisdiction over which belongs entirely to *H.*, although the river flows from the port to its mouth through the territories of Prussia, form the principal part of the expenditure. The public debt of *H.* in 1878 amounted to 125,678,520 marks, or \$31,419,630. In 1878 the population (including

*man Bank* and the *Union Bank*, established in 1856, each with a capital of \$7,500,000. They discount bills, make advances on goods, and transact all sorts of banking business. The exchange business done at *H.* is very great: for, besides the business of the place, most of the merchants in the inland towns have their bills negotiated there.

**Money, Weights, and Measures.** The inconveniences of the old system of money, weights, and measures of *H.* have disappeared with the introduction of the new system, which is obligatory for all the states of the Empire (see GERMANY). As, however, the old weights and measures are still frequently used in commercial transactions, we give here their English equivalents:—

Hamburg.	MEASURES.	British.
100 feet in length.....	=	94.021 feet in length.
" square.....	=	88.400 feet square.
" cubic.....	=	83.115 feet cubic.
100 ells (of cloth).....	=	18,961 yards.
100 barrels (fass) of corn.....	=	18,961 imperial quarters.
100 quarters (viertel) of liquid.....	=	159.470 imperial gallons.
1 common last of 6,000 lbs.....	=	2 tons burden.
1 old ship last of 4,000 lbs.....	=	2 tons burden.
1 corn last.....	=	11½ imperial quarters.
1 coal last of 22 tons.....	=	2 tons avoirdupois.

WEIGHTS.	
100 new lbs. or 1 centner.....	= 110.232 avoirdupois.
100 marks bank weight.....	= 62.6554 lbs. troy.

**Long Measure.**—The *H.* foot, divided into 12 inches, of 8 parts each = 0.28357 mètres = 127.036 Parisian lines = 11.239 Eng. inches. Hence,

100 Hamburg feet = 94.021 English feet.
100 " " = 28.657 French mètres.
100 " " = 91.307 Prussian or Rhenish feet.
100 " " = 90.664 Vienna feet.

The *H.* ell (short ell) = 2 Hamburg feet. 65.7314 mètres = 254.072 Paris lines. 100 Hamburg ells = 62.681 Eng. yards.

The Brabant ell (or long ell) most commonly used in *H.* in measurement of piece goods = 27.585 Eng. inches.

**Liquid Measure.** 1 fuder = 6 aums, 1½ aums = 4 ankers or 5 elmers; 1 anker = 5 viertels; 1 viertel = 2 stübchens; 1 stübchen = 2 kannens; 1 kannen = 2 quarters of Oessel; 1 elmer = 4 viertels; 1 hoghead = 1½ aums, or 6 ankers, or 30 viertels, each of 8 quarters or hottles.

The stübchen contains 265 *H.* cubic inches = 3.62 litres.

100 Hamburg viertels = 159.39 English imperial gallons.
100 " " = 724.18 French litres.
100 " " = 632.45 Prussian quarters.
100 " " = 511.88 Vienna maas.

The full beer barrel contains 48 stübchens, or 192 quarters; the small barrel only 32 stübchens, or 128 quarters.

The vinegar barrel contains 30 stübchens, or 120 quarters.

The whale and fish oil barrel contains 32 stübchens, or 128 quarters; 2 whale oil barrels = 1 quartel.

**Grain Measure.** Corn is sold by weight, and the last is supposed to contain in

	lbs. avoird.		lbs. avoird.
Wheat.....	5,400	Malt.....	3,000
Rye.....	5,100	Pease.....	3,000
Barley.....	4,800	Beans.....	5,520
Oats.....	3,600		

In practice one *H.* last is taken at 11 imperial quarters, 31 hectolitres, 57 Prussian scheffels, 25 Danish barrels, and 10½ Russian chetverts.

The coal barrel contains (when the 1.453 *H.* cubic inches of head or heaped measure is added) 16.433 cubic inches.

The *H.* ship last, or last of commerce, really weighs 6,000 pounds, or 3 tons (not 4,000 pounds, as is generally stated).

**Duties.** There are no export duties, and the import duty is only ½ per cent. The following articles are free even of this low duty: 1. Wool, raw cotton, silk, flax, yarn and manufactured goods of flax, hemp, rags, old rope, used linen cloth, and empty bags; 2. Corn, potatoes, and rape-seed; 3. Unmanufactured copper and brass, copper ore, rough spelter and old zinc, nickel and nickel ore, cobalt and cobalt ore, bell metal, and old metal vessels, etc., for smelting; 4. Bullion and coin, unworked gold and silver, waste derived from the precious metals, gold dust, silver ore and ore containing silver, precious stones not set, pearls, and jewels; 5. Printed books, music, maps, etc.; 6. Oil-cakes, bark, bones, offal of various kinds, guano, and blood manure; 7. Coals, cinders, turf, timber, staves, and wood for burning, chalk and limestone, slates, cement and cement stone; 8. Live animals, with the exception of oysters and beeches, game and poultry, fresh fruit, and various agricultural productions; 9. Passenger luggage, dowries and heritages; but in part under certain conditions and restrictions. — **Goods in Transit.** Not only *H.* citizens, but foreigners, are enabled to declare goods *in transitu* upon payment of a

fee of 25 marks courant on the transaction, and depositing or giving security to the government for 1,000 marks banco. The levy of duties in *H.* is conducted in the simplest manner, and on the most liberal footing. No vexatious forms check the free intercourse or the free course of trade: the entry for duty is merely a declaration of the current value at the time: transitu articles remaining in warehouse for exportation require a mere declaration to that effect by a burger or citizen. In levying duties no advantage is claimed by *H.* for vessels bearing her own flag: goods by all vessels, from whatever quarter of the world, paying the same duties. Though she now carries the German flag, she, like the other Hanse Towns, remains a free port outside the customs frontier until she signifies a wish to be admitted to it. But for this privilege she is obliged to pay an annual sum, called an *aversum*, equivalent to the customs duties that would otherwise have been levied within its territory. It amounted to \$511,500 in 1878, equal to a charge of \$1.98 per head of population. The low rates of duty in *H.* is a proof of her anxious desire to encourage trade with all nations: and the more so when we consider the great expense she is put to in keeping up buoys along the Lower Elbe, and other necessary charges for navigating that river; expenses which considerably exceed the total sum received for duties.

**Custom House Regulations.** On a vessel's arrival at *H.* the broker reports her to the custom-house, gives his guaranty for payment of the duties, delivers her papers, and the vessel is allowed to unload. On clearing, a manifest of the outward cargo, together with the consul's certificate of the regularity of the ship's papers, must be produced at the custom-house by the broker, who obtains in return a clearance certificate, authorizing the vessel to go to sea.

**Insurance, etc.** All sorts of insurances are effected at *H.* A municipal regulation compels the insurance of all houses within the city, the rate varying according to the number of fires and the amount of loss. Marine insurance is principally effected by joint-stock companies, of which there are several; their competition has reduced the premiums to the lowest level, and the business is not understood to be profitable. The high duties on policies of insurance in England have led to the insuring of a good many English ships at *H.* Life insurance is not prosecuted in Germany to any considerable extent.

**Bankruptcy.** Considering the vast number of merchants and tradespeople at *H.*, bankruptcy is not, in general, of frequent occurrence. Much of the business transacted at *H.* being on commission and for account of houses abroad, the failure of foreign merchants is a prevalent source of bankruptcy. Another source of bankruptcy is losses on goods imported or exported on speculation, and occasionally losses in the funds, in which a good deal of gambling goes on here. Expensive living is not nearly so prevalent a source of bankruptcy here as in New York, London, and other places.

**Navigation of the Elbe, and Pilotage.** The mouth of the Elbe is enumbered with sand-banks. The channel leading to Cuxhaven is bounded on the N. by the Vogel Sands and North Grounds, and on the S. by the Schaarhorn Sands and Newwerk Island. On the latter there are 2 light-houses and 2 beacons, and on the Schaarhorn is another beacon. The light-houses on Newwerk Island are about 500 yards apart; the most southerly, which is also the most elevated, being in lat. 53° 54' 57" N., lon. 8° 29' 40" E. It is 128 feet high, being twice the height of the other. The channel is, in some places, hardly ½ of a m. wide. The outer red buoy is in the middle of the channel at its mouth bears from Heiligoland S. E. by S., distant nearly 20 m. But the best mark in entering the Elbe is the floating light, or signal ship, moored 2 m. N. W. by N. of the red buoy, in 11 fathoms at low water. This vessel never leaves her station unless compelled by ice in winter. By night she exhibits a lantern light, 38 feet above deck, and in foggy weather rings a bell every quarter of an hour. A second signal ship is stationed 5½ m. S. E. by E. from the first, at the westernmost point of a sand-bank dividing the fair way of the river. She is rigged like a galliot, to distinguish her by day from the first signal ship; and during night she exhibits two lights, one 18 feet above the other. The distance from the outer red buoy to Cuxhaven is about 16 m.; thence to Glückstadt the course is E., 28 m.; from the latter to Stade the course is southeasterly, 9 m.; and then easterly to *H.*, 18 m. The channel throughout is marked with black and white buoys, which are numbered and specified in the charts. The black ones are to be left in passing up the river, on the starboard, or right-hand side, and the white on the larboard side. All vessels coming from sea into the Elbe, which measure above 60 commerce lasts at 6,000 lbs. each, must pay pilotage whether they require a pilot or not; and however well the signals, lights, beacons, and buoys may be arranged, the services of an experienced pilot are very necessary, especially in the case of fogs or stormy weather. To assist in getting vessels supplied with this indispensable functionary, a schooner was directed in 1855, to cruise between Heiligoland and the mouth of the river, to be in readiness to supply ships with pilots and instructions; and this plan having been found to answer extremely well, a second schooner has since been employed for the same purpose. Previously to this arrangement vessels had to heave to by the pilot-galliot, moored near the river's mouth;

and when, owing to the state of the tide or the weather, they could not do this, they had to sail to Cuxhaven and there get a pilot. But the schooners being extremely good sea-boats, and always on the lookout, their employment has greatly reduced the inconveniences that formerly attended the shipping of pilots. The charges on account of pilotage vary, of course, with the vessel's draught of water, the distance she has been piloted, and sometimes also with the nature of the cargo. They are in all cases very moderate. The charge for towage is fixed per agreement.

**Hamburg Blue.** See Bice.

**Hamburg Lake,** a cochineal lake color, rather purplish, or inclining to crimson.

**Hame,** one of the pair of lyre-shaped pieces of wood or metal inserted into the groove of a horse's collar, to which the traces of the harness are fastened.

**Hameçon [Fr.],** a fish-hook.

**Hamilton,** a fire-insurance Co., located in New York City, organized in 1852. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$150,000; net surplus, \$124,536.95; risks in force, \$10,268,253; premiums, \$56,188.13; premiums received since the organization of the Co., \$1,700,530.90; losses paid, \$761,718.75; cash dividends paid to stockholders, \$384,750.

**Hammer,** a tool used by mechanics, which consists of an iron head fixed crosswise upon a handle. The *H.*, however, employed in the useful arts vary greatly in form, and the weights of individual examples may be estimated from several tons to the fraction of an ounce. The *H.* used by blacksmiths are of several kinds. Among others are the *about-sledge*, which is the largest of all, and is held by both hands at the furthest end of the handle, and being swung at arm's length above the head, is made to fall heavily upon the work. The

Fig. 257. — HIGH-FRAME STEAM-HAMMER.

*up-hand sledge* is not so large, but is used with both hands, and seldom raised above the head. The *hand-H.* is the smallest, and may be used with one hand at the anvil. The class of *H.* called *riveting-H.* have the handle fixed to them by passing it through a hole in the head, where it is made to fit or be wedged firmly; the face is formed of steel, as well as the riveting end, and welded to the iron. These *H.* are used by carpenters, smiths, engineers, and numerous artisans, varying in size and form according to the purpose for which they are required. A variety of *H.* having two claws, called *claw-H.*, are much used by carpenters and

other mechanics, as the claw, together with the handle, forms a powerful lever for drawing out nails, etc. The largest *H.* are those used in the manufacture of iron. In this form they are not mere tools, but machines moved by steam or some other power. There are many varieties. *Frothing's forge-H.*, which is used for heavy castings, as well as for edge-tools, knives, files, etc., may be moved either by hand, water, or steam power. A heavy hammer-head, with a guide-rod, cones, and vertical spring, accomplishes the work by means of a driving shaft made to rotate by any source of power. In *Hutton's power-H.* the weight is raised by a strap or chain, attached to a drum or pulley on an axis; when the blow is struck, the momentum is made to assist in raising the *H.* again. This *H.* is much used in beating iron and steel between pairs of dies. The *frictional-action-H.* can be worked by any continuously revolving power-shaft, and can be made to hammer 150 blows per minute with a very heavy hammer-head. *Cotton's air-tilt-H.* and *Waterhouse's compressed-air forge-H.*, for light work in a smith's shop, are also useful varieties; and there are many more. The powerful machine called the *steam-H.* was originally invented by Mr. Nasmyth, in 1842. In its latest developments this is certainly one of the most important machines known to the mechanical engineer. As usually constructed, there is a mass of iron called the *H.-block*, weighing sometimes several tons; and a smaller mass fixed to the lower part of it constituting the *H.* This *H.* works upon an *anvil*, embedded in the upper surface of a ponderous mass called the *anvil-block*, so supported by a solid foundation as to be able to bear almost any amount of concussion. Rising from the ground are two *standards*, so arranged as to retain the moving part of the mechanism between them; these standards are joined at the top by a *lintel* (Fig. 257). A small *steam-engine* is upheld mainly by the lintel, with steam-cylinder, valve-box, piston-rod, steam-chest, and other accessories, all specially adapted to this kind of work. The steam-boiler may be at any convenient distance, and steam brought from it through a jacketed steam-pipe. The arrangement is such that, when steam enters the cylinder below the piston, the piston is driven up, and drags up with it the *H.-rod*, *H.-block*, and *H.*; when the steam escapes through a valve to the waste-pipe, the *H.* and its appendages fall with tremendous force by their sheer weight. There is self-acting gear, which arrests the rise of the piston at any required height, thereby giving to the *H.* any desired depth of fall. When once adjusted the *H.* will continue its lusty blows with uniform power; a slight change made by an attendant will vary either the rapidity of the blows or height of the descent, or both, and another slight movement will stop the action altogether. All the detailed mechanism which enables one single workman to do this is exceedingly beautiful, especially that in which some of the steam is made to act as an elastic cushion or spring. We have seen the same steam-*H.* crush an iron bar an inch thick, and then, by a simple movement of a handle, give taps so gentle as to descend upon a nut without cracking the shell. The first steam-*H.* that were made had *H.-blocks* of about 1½ cwt. each; but the machine has since been vastly increased in weight and power, inasmuch that there are now examples varying from 2 cwt. to 20 or 30 tons. At Krupp's celebrated steel-works at Essen, in Prussia, there is one steam-*H.* said to be 50 tons in weight, with a cylinder 6 feet in diameter; the blows which it

hurls are received upon an anvil weighing no less than 185 tons. There are nearly 50 steam-*H.* of various sizes at these gigantic works. A *duplex* steam-*H.* has been invented, and partially brought into use, having two horizontal cylinders, and two *H.* which approach each other horizontally, squeezing and thumping any object (such as a mass of red-hot iron) that comes between them.

**Hammer-Axe**, a double tool, having a hammer at one side of the handle and an axe at the other.

**Hammer-Beam**, a tie-beam.

**Hammer-Cap**, a cover for the cock of a gun.

**Hammer-Cloth**, an ornamental covering to the coachman's seat, principally used for the more elegant kinds of coaches.

**Hammerer**, a blacksmith; a worker on metal at an anvil.

**Hammer-Head**, the solid shaped piece of iron which is fitted to a handle for striking with, and which is sent in large quantities, or strings, packed in casks, to different ports.

**Hammer-Helve**, the shank of a forge or trip-hammer.

**Hammerman**, a name in Scotland for a smith.

**Hammer-rail Maker**, a manufacturer of parts of the machinery for a piano-forte.

**Hammock**, **Hamac**, a kind of hanging bed, which is suspended between trees or posts, or two hooks. The true Indian *H.* is a long narrow net made of strong cord, and terminated at each end by small ropes for suspending it. The *H.* used on board ship consists of a piece of stout canvas, about six feet long and three broad, gathered at the ends and suspended by cords. The sailor's *H.* is an oblong piece of hempen cloth; at each end are fastened several small lines, meeting in a grummet or iron ring; these form the *clews*. The whole, having mattresses, pillows, etc., placed in it, is hoisted up into its place by small ropes called *laniards*, between two battens or screws in the beams of the deck overhead, about nine feet distant asunder. The *H.* is a very agreeable bed, especially in cold weather; but some little practice is requisite at first in getting in and out successfully. During the day the *H.*, lashed up tight in the form of caterpillars, are stowed in the nettings along the upper edge of the bulwark.

**Hamper**, a large wicker-work covered basket.

**Hampton Roads**, a branch of Chesapeake Bay, off the mouth of James River, between Old Point Comfort on the N. and Willoughby Point on the S., Virginia. It is sufficiently deep for the largest ships of war, and is an important naval rendezvous. On Old Point Comfort is Fort Monroe, and on the opposite point, one mile distant, is Fort Calhoun, which completely commands the entrance to Hampton Roads. On the N. side of the entrance is *Old Point Comfort Light*, lat. 37° 6', lon. 79° 18' W., showing a fixed light on a white tower, and elevated 40 feet above the surface of the sea. On the south side of the entrance the *Willoughby Spit Light Vessel* shows fixed lights, elevated, the one 32 and the other 41 feet above the sea-level; and here is a fog-bell also. The channel leading from the Capes of Virginia to Hampton Roads is reduced at *Old Point Comfort* to a narrow width. The shoal water, under the action of the sea and the reaction of the bar, is kept in an unremitting ripple; which circumstance has given to this place the name of the *Rip Raps*.

**Hamster**, a small rodent animal, the *Cricetus*

*fromentarius*, the fur of which is used for many purposes. The animal is very plentiful in Germany.

**Han**, a caravansary or inn in the Levant.

**Hand**, the palm. — A measure of four inches used for ascertaining the height of horses. — The index finger of a watch, clock, or counter. — A set of cards. — A workman. — The form of writing or penmanship. — A bundle or head of tobacco-leaves tied together without the stem being stripped.

**Hand-Ball**, a small stuffed ball for children's amusement.

**Hand-Barrow**, a frame or tray, with handles at each end, carried between two persons.

**Hand-Basket**, a portable basket with handle.

**Hand-Bell**, a small portable sounding instrument, rung by the hand, often kept on a table for summoning servants.

**Handbill**, a chopper or pruning-hook. — A small printed sheet distributed by hand to persons, or delivered from house to house.

**Hand-Book**, a manual of reference.

**Hand-Brace**, an instrument to hold a boring tool.

**Hand-Breadth**, the palm; the size of the hand; a measure of 3 inches.

**Hand-Bucket**, a small leather bucket or wooden pail that is easily lifted.

**Hand-Churn**, a box for making butter, worked by the hand.

**Hand-Crank**, a crank turned by the hand.

**Handcuffs**, iron shackles or manacles for the wrist.

**Hand-Fork**, a prong; an agricultural implement.

**Handful**, a small quantity of anything; as much as can be grasped in the hand.

**Hand-Gallop**, an easy pace of a horse.

**Hand-Gear**, the contrivances for working steam-engine valves.

**Handglass**, a small glazed frame for sheltering and forwarding out-door plants.

**Hand-Grenade**, a grenade to be thrown by the hand.

**Hand-Guide**, an instrument for insuring to the player a good position of the hands and arms on the piano-forte.

**Hand-Hammer**, a workman's tool; a small, light hammer. See **HAMMER**.

**Hand-Hook**, a bent instrument used by smiths in twisting square iron.

**Handicap**, a weight-for-age race for horses.

**Handicraftsman**, a mechanic or artificer; an artisan or hand-worker.

**Handiness**, neatness, skill, dexterity.

**Hand-Kase**, a kind of cheese made in Germany from sour milk.

**Handkerchief**, a silk, cotton, or linen cloth, usually square, varying from 8 to 22 inches in size, and used to wipe the face. — A piece of cloth worn about the neck; a neckerchief.

**Handle**, the haft; the part of anything taken in the hand, by which it is used or lifted, as of a saucepan, a knife, a sword, etc. See **HAFT**.

**Hand-Lead**, a small lead fastened to a line, used for sounding in rivers and harbors, or for ascertaining the depth of wells, etc.

**Hand-Light**, a portable lantern; a blue light.

**Hand-Line**, a small fishing-line.

**Hand-Mallet**, a wooden hammer or beater.

**Handmill**, a quern; a small iron mill for grinding grain, pepper, coffee, or other articles, worked by the hand.

**Hand-Money**, earnest-money, the money paid

at the closing of a contract of sale by the purchaser.

**Hand-Plane**, a carpenter's smoothing or facing plane.

**Hand-Rail**, a leaning support in a ship. — A stair rail supported by balusters.

**Hands**, a sea-term for the sailors or available force of a ship; factory workmen; dock-laborers, etc.

**Handsaw**, the largest saw used by hand.

**Hand-Screen**, an ornamental screen for keeping off the heat of the fire.

**Hand-Screw**, a jack or engine for raising heavy timbers or weights.

**Handsel**, an earnest-money paid to close a bargain. See **EARNEST**.

**Handsomely**, in nautical language, dexterously, slowly, carefully.

**Handspike**, a long wooden bar used for turning a windlass, etc.

**Hand-Staff**, a stout walking-stick. — The upper or holding part of a flail.

**Hand-Vice**, a small portable vice.

**Hand-Work**, work effected exclusively by the hands, without the intervention of machinery.

**Handwriting**, the cast or form of writing peculiar to a person.

**Handy-Billy**, a watch-tackle in a ship.

**Hangar** [Fr.], a shed; a cart-house; coach-house.

**Hanger**, a seaman's cutlass, a short round curved sword. — That by which a thing is suspended.

**Hanger-On**, a miner employed at the bottom of the shaft, in fixing the skip or bucket to the chain.

**Hangings**, tapestry or curtains; room-papers.

**Hanging-Shelf**, a suspended shelf in a pantry or room, to avoid rats.

**Hanging-Sleeves**, large loose sleeves to a lady's dress.

**Hang-Net**, a net with a large mesh.

**Hank**, a coil. — A skein or head of thread, silk, or cotton, etc.; two or more threads twisted and tied together; a yarn-measure which, for cotton yarn, consists of 7 leas or 480 yards; for worsted yarn the leas are longer, making the length of the hank 560 yards. — One of the rings or hoops of wood, rope, or iron round a stay in a ship, to secure a sail to.

**Hankow**. See **CHINA** (Seaports).

**Hannibal and Naples R.R.** runs from Naples, Ill., to Hannibal, Mo., 49.6 m. This Co., whose offices are in Springfield, Ill., was chartered in 1863, and the road opened in 1870. The Wabash R.R. Co. leases and operates it. *Financial statement*: Cap. stock, authorized \$750,000, paid in \$457,000; funded debt, \$700,000, as follows, — 1st mortgage 7% bonds, issued 1868, \$675,000, payable 1888 (interest May and Dec.), and 2d mortgage 7% bonds, issued 1870, \$225,000, payable 1890.

**Hannibal and St. Joseph R.R.** runs from Hannibal to St. Joseph, Mo., 206.41 m., with branches from Cameron to Kansas City, Mo., 53.05 m.; from St. Joseph, Mo., to Atchison, Kans., 19.47 m.; and from Palmyra, Mo., to Quincy, Ill., 13.42 m.; making a total of 292.35 m. owned and operated by the Co. This Co., whose offices are in Hannibal, was chartered in 1847 and opened its main road in 1859. It has received a land-grant by act of Congress, and loans amounting to \$3,000,000 from the State of Missouri. The bridge over the Missouri River, at Kansas City, is the property of this Co., which allows its

use under contract by the St. Louis, Kansas City, and Northern R. R. Co., and the Kansas City, St. Joseph, and Council Bluffs R.R. Co. *Financial statement*: Cap. stock, common, \$9,168,700, and preferred, \$5,083,024, total \$14,251,724; funded debt, \$8,633,000, as follows, — Convertible mortgage 8% bonds, 15-year bonds, payable 1885, \$4,000,000; Missonri State loan, 6% bonds renewed, \$3,000,000, of which \$500,000 are payable in 1886, \$1,000,000 in 1887, and \$1,500,000 in 1894; 2d mortgage (Quincy and Palmyra) 8% 30-year bonds, payable 1892, \$433,000; 1st mortgage (Kansas City and Cameron) 10% 30-year bonds, payable 1892, \$1,200,000. There is besides a land-grant mortgage secured on the Co.'s land-grant contracts assigned to the Farmers' Loan and Trust Co. in 1878. These bonds, of which the amount of \$1,000,000 was authorized and \$532,000 sold, are payable in 1888, interest 7%. These bonds are to be cancelled by successive drawings of \$25,000 each, of which 6 have already taken place, leaving \$850,000 uncanceled. There are still about 90,000 acres of unsold land.

**Hanover**, a former kingdom of Germany, now annexed to Prussia. See **PRUSSIA**.

**Hanover**, a fire-insurance Co. located in New York City, organized in 1852. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$500,000; net surplus, \$675,898.84; risks in force, \$84,791,280; premiums, \$342,064.32; premiums received since the organization of the Co., \$9,476,468.33; losses paid, \$4,923,791.99; cash dividends paid to stockholders, \$884,500.

**Hanse Towns**, a name given to certain towns situated in the N. of Europe, which formed in the 13th century an association called the *Hanseatic League*, having for its object the protection of mercantile property. It was so called from an old German word signifying union. The first point with the confederates was to repress the seizure of merchant vessels by pirates, and the robbery of goods conveyed by land; the next was to obtain justice in regard to the claims of merchants in courts of law, — a matter of no small difficulty in those rude times. The town which took the lead in forming this association was Lubeck, the trade of which had become considerable in the 13th century, chiefly from its position. Situated at the S. E. point of the Baltic, it was the natural entrepôt for the trade of Prussia, Poland, and Livonia with the N. W. of Germany, in the same manner as Hamburg, from its ready access to the North Sea, was the fit port for communicating with the Netherlands and England. The distance between these towns by land being small (only 40 m.), frequent conferences took place in regard to their mutual interests; and the result was their concluding a treaty in the year 1241, by which they bound themselves to use their utmost efforts for the protection of trade. Brunswick, then the chief inland town in the N. W. of Germany, and connected in trade with both Lubeck and Hamburg, acceded to the treaty shortly afterwards; and in 1252 deputies from each of the three met at Lubeck, where, among other arrangements of importance, they took steps for establishing factories in London, Bruges, and Novgorod in Russia. Being open to new members, they were joined in the course of the next century by a number of cities, such as Amsterdam and other ports in the Netherlands, Dantzic, as well for itself as for the lesser towns in the N. of Poland, and Cologne, for the different trading places on the Rhine. The confederacy attained its greatest power in the 15th and 16th centuries, when the league comprised no

fewer than 64 commercial places; and was capable of conducting extensive naval operations, and of asserting its rights by force of arms. As civilization diffused itself, however, in the N. of Europe, and the different governments made a point of protecting trade as well by sea as in their respective territories, less exertion was required on the part of the Hanse Towns. It became evident, also, from the example of Holland, that trade prospered most when each mercantile district or seaport was left to manage its own concerns. Hence a gradual relaxation in the bonds of the confederacy, so that Lubeck, Hamburg, and Bremen are all that continue to acknowledge the authority of the League. To this day they preserve the shadow of its power, being still acknowledged as free Hanseatic cities. But their enforced embodiment since 1872 in the German Empire, and association with the other German States in the Zollverein, will cause even this shadow to lessen very rapidly. The high court of appeal for the three Hanse Towns, reorganized by treaty of Nov. 30, 1866, after the incorporation of Frankfort-on-the-Main with Prussia, is established at Lubeck. It is composed at present, under a convention signed July 2, 1872, of a President, nominated by the Senates of the three Free Cities, and 6 councillors, 3 of whom are chosen by Hamburg, 2 by Bremen, and 1 by Lubeck. The supervision of the Court is in the Senate of the three cities, passing in rotation from one to the other on the 22d of July of every year.

**Hansom Cab.** See **CAB.**

**Haou,** a name in China for the tenth part of a dollar.

**Hapse.** See **HASP.**

**Harbaia,** a measure of capacity, used in Tripoli and other parts of Northern Africa, equal to about 20½ lbs.

**Harbor,** a technical name, in the glass-trade for a chest 6 or 7 feet long to hold the mixed ingredients previous to being put in the pot for fusion.

**Harbor, Haven, or Port,** a piece of water communicating with the sea, or with a navigable river or lake, having depth sufficient to float ships of considerable burden, where there is convenient anchorage, and where ships may lie, load, and unload, screened from the winds, and without the reach of the tide. There is every variety in the form and quality of harbors. They are either natural or artificial; but, however formed, a good harbor should have sufficient depth of water to admit the largest ships at all times of the tide; it should be easy of access, without having too wide an entrance; the bottom should be clean and good; and ships should be able to lie close alongside quays or piers, that the expense and inconvenience of loading and unloading by means of lighters may be avoided. Ships lying in a harbor that is land-locked, and surrounded by high grounds or buildings, are at once without the reach of storms, tides, and currents, and may in most cases be easily protected from hostile attacks. Bar harbors are those that have bars or banks at their entrances, and do not, therefore, admit of the ingress or egress of large ships except at high water. These are most commonly river harbors; the sand and mud brought down by the stream, and driven back by the waves, naturally forming a bar or bank at their mouths. The reader will find all the harbors of any importance in the U. States, and the principal foreign commercial harbors, described in this work under their respective titles, or the names of the states or countries to which they belong.

**Harbor-Dues,** the charges made to ships for using a harbor and moorings, etc.

**Harbor-Light,** a light to guide ships on entering a harbor.

**Harbor-Master,** the officer in charge of a port who has the superintendence of the shipping.

**Hardbake,** a kind of sweetmeat of baked sugar, sometimes with blanched almonds.

**Hardener,** one who brings tools down to the proper temper.

**Hardes** [Fr.], clothes, luggage, apparel.

**Hardness,** compactness; solidity; the power of resisting abrasion. Mineral substances are frequently distinguished and identified by their relative hardness. The method pursued in constructing the following and similar tables of the hardness of different substances is by observing the order in which the articles tried are capable of cutting or scratching one another.

**Hard-Roe,** a female fish, or spawner.

**Hardware** [Fr. *quincaillerie*; Ger. *kurze Waaren*; It. *chincaglio*; Port. *quincaharia*; Sp. *quinquilleria*], a general term for goods manufactured from the commoner or more useful metals; that is, iron and steel, brass and copper, zinc and tin. It is not easy to name the limit to which this trade extends, owing to the multiplicity of articles to which the name *H.* is given. It extends occasionally to certain commoner kinds of plated goods, but does

not include machinery, agricultural implements, and cutlery, though articles belonging to the two last-named departments of trade are commonly sold in *H.* stores.

**Hard-Wood**, a name applied to heavy, close-grained-woods, chiefly used by cabinet-makers and turners; among *H.-W.* belonging to the U. States are walnut, white oak, chestnut, wild cherry, ash, hickory, maple, cedar, locust, etc. In America, the term *H.-W.* is frequently applied commercially to other woods than firs, pines, or spruce.

**Hare**, a rodent animal, which is hunted and shot for its flesh and for its skin. See *FUR*.

**Haricot**, French or kidney bean.

**Harina**, the Spanish word for flour.

**Harkem**, a Belgian rake or harrow.

**Harle**, the reed or brittle stem of flax, separated from the filament.

**Harlem Extension R.R., South**, runs from Chatham Four Corners, N. Y., to Bennington, Vt., 58 m. This Co., whose offices are in New York, is the N. Y. portion of the line formed in 1870 by the consolidation of the Lebanon Springs and the Bennington and Rutland R.R. Cos., and which was taken possession of in 1876, by trustees under foreclosure. It has since been operated, under lease, under the name of Harlem Extension R.R. South Coal Transportation Co. *Financial statement* previous to the separation of the two roads: Cap. stock, \$4,000,000; funded debt, \$4,000,000, consisting of 1st mortgage 7% bonds issued in 1870 and payable in 1890.

**Harlem River and Port Chester R.R.** runs from the Harlem River to New Rochelle, N. Y., 11.80 m., and has its offices in New York City. The original Co., which was chartered in 1866, became embarrassed, and the road was completed by the New York, New Haven, and Hartford R.R. Co., who made it a branch of their own line, leasing it at the rate of the interest on the bonds, \$130,000 per annum. *Financial statement*: Cap. stock, \$42,160; funded debt, 1st mortgage 6 and 7% guaranteed bonds issued in 1873, payable in 1903, \$2,000,000.

**Harmonica, Musical Glasses**, a musical instrument in which the sounds are produced from glasses blown as nearly hemispherical as possible, each having an open neck or socket in the middle into which a perforated cork is fitted.

Near the brim the glass is about one tenth of an inch thick, but increases towards the neck, which is in the largest about one inch deep and half an inch wide within, the dimensions lessening in proportion as the glasses diminish in size, all excepting the smallest, which ought not to be less than half an inch in length. The largest glass is nine inches in diameter, and the smallest three; between these there are twenty-three different sizes. They are distinguished by painting the apparent parts of the glasses on the inside—every semitone white, and the other notes of the octave with the seven prismatic colors, so that glasses of the same color, white ones excepted, are always octaves to each other. The glasses are placed on a round iron spindle (fixed horizontally in the middle of a box, and made to turn on brass gudgeons at each end), one within the other, each leaving about an inch of its brim above that of the other. The spindle is turned by means of a foot-wheel, and the tones produced by rubbing the exposed parts of the glasses with the ends of the fingers damped and rubbed with chalk to bring out the tone more readily. The glasses also should be occasionally wetted with a sponge and clean water. The production of the sound by means of the naked finger is said to have such an effect upon the nervous system as in some cases to have caused fainting-fits. Many attempts were made to play it by keys, but none have succeeded, no dead substance having been yet found capable of giving the same expression to the sound as the human fingers.

**Harmonicon**, a musical instrument, whence the sound is obtained by striking with a cork on pieces of glass, or on metallic plates, loosely suspended. It is a popular and cheap toy, largely imported from Germany.

**Harmonimeter**, an instrument for ascertaining the harmonic relation of sounds.

**Harmoniphon**, a small musical instrument with a key-board, in which the sounds are produced from small metal tongues, acted upon by blowing through a flexible tube.

**Harmonium, Melodeon, Seraphine**, a musical instrument which bears some affinity to the organ, but, unlike that instrument, is made upon a principle technically termed the *free vibrating reed*, which is said to have been known from an early period in China, but was invented by Grenié in 1810, and first described by Biot in 1817.

The free reed consists of a brass plate containing an oblong slit, having a thin elastic tongue fixed to one end in such a manner, and so exactly fitting into the slit, as to completely close it, but so that it will, upon the pressure of the wind on the free end, pass either inwards or outwards, without touching the end or sides. It has several advantages over the beating-reed of the organ. In the first place, its tone is of a more agreeable quality; secondly, it requires no pipe, which is an indispensable addition to the organ; thirdly, it is much less liable to get out of order; and fourthly, it gives an entirely new property, — *viz.* the power of *expression*. Debain, of Paris, was the first to construct a keyed instrument upon the free-reed principle of a really useful character. Several attempts had been made, but all had more or less failed, until Debain invented the harmonium. This instrument is about 3 feet high by 3 feet 9 inches broad, its depth varying according to the number of stops. The key-board is immediately below the lid, and its compass extends five octaves, from C to C. This now, however, in the best instruments, is virtually converted into seven by the more perfect arrangement of the stops. The valves are beneath the key-board and on top of the wind-box, within which are the different rows of reeds, the pitch of which is regulated by their size, which varies from half an inch to 3½ inches in length, whilst the quality of the sound is modified by the breadth of the vibrating portion and the shape of the hole covered by the valve. The wind is supplied by means of bellows with two feeders, which the player moves alternately with his feet. For the deep bass notes the springs are heavily loaded at the loose end, to make them vibrate slowly; while for the higher notes they are made thinner at that end. Some harmoniums have only one row of reeds, others four; some also have two rows of keys. Lately a "knee movement" has been introduced, by which a small degree of crescendo may be produced on either bass or treble.

Fig 253. — ACCORDION.

The *accordion*, or *accordeon*, is a musical instrument which differs from the harmonium in size and the mode of manipulation, but is constructed on the same principle. It consists (Fig. 253) of a small oblong box, of from 8 to 20 inches in length, with an inside row of small elastic springs, or laminae, fixed in a metallic plate at one end in such a manner as to allow them to vibrate freely. A bellows, or folding apparatus, unites the upper and lower parts, and supplies the springs with the necessary air to put them in motion. To these the air is admitted by valves, which, in the same manner as in an organ, are acted on by the keys. A bass note, or drone, is also added. The compass of the most perfect instrument is from G, the fourth space on the bass clef, to E, the seventh additional space above the treble, all the semitones inclusive. See *ORCHESTRON*.

**Harness**, the gear and trappings for a carriage or draught horse, including all that is placed on the horse when at work, and by which the animal is attached to the carriage. See **SADDLERY**.—The contrivance in a loom by which the sets of warp-threads are shifted alternately to form the shed. See **LOOM**.

**Harness-Cask**, a cask or high tub with a lid guarded by a rim which comes a small way down the cask; used on board ship for keeping salted meats ready at hand for daily use.

**Harness-Clamp**, a kind of vice having a pair of jaws closed by a spring, wedge, or screw, and used by saddlers to hold leather while being stitched.

**Harness-Pad**, a lining or soft wad beneath a saddle, to keep the harder portions from galling the back of the horse.

**Harness-Plate**, the plated bits, buckles, rings, etc., on harness.

**Harness-Saddle**, that part of the harness resting across the back, and to which the girthing portions are attached.

**Harness-Smith**, a metal-worker who forms the iron-work for saddlery.

Fig. 259. — EGYPTIAN HARP  
(From a painting at Thebes.)

**Harp** [Fr. *harpe*; Ger. *Harfe*], a well-known musical instrument of great antiquity, and which, in biblical and heathen records, holds a most exalted rank. To attempt giving exact information on its origin would be a task impossible to accomplish, as it seems lost in the darkness of ages. Moses tells us that Jubal, the son of Lamech the first, was "the father of all such as handle the *H.* and the organ." The *H.* soothed the frenzied soul of the lion-hearted king of the Jews, when played by David, the young poet-harpist of Israel; and the sight of the *H.*, which the stricken Hebrews had carried from the falling towers of Jerusalem, consoled their exile while they hung the beloved instruments, which they were not allowed to play, upon the willows as they sat down in their desolation by the waters of Babylon. Among the Greeks, Mercury was "the sweet parent of the bending lyre," and no epithet more chaste and beautiful has been applied to the land of Homer, than "the land of lyres." But monuments have outlived history. Bruce discovered frescos of the harp near the ruins of Thebes, believed to have been executed under Sesostris, at least 14 centuries before Christ.

These harps (Fig. 259) so closely resemble the modern, that at a glance they might be taken for those of our own times. The harp was used as

an accompaniment in singing their Psalms by the congregations of the early Christians. It waked the echoes of the old Welsh mountains while the white-haired bards rehearsed the history of their nation in verse. It led the festivities of every palace, and lent its charms to every lady's chandoir or troubadour's song of love. It sent its soft murmurs through the lofty arches of the stately cathedrals of the Middle Ages, and is the only instrument which links the melody of earth with the songs of heaven. The Welsh harp was strung with gut, while the Irish harp (Fig. 260) was strung with wire. The harp, that favorite instrument of all nations, was much improved during the last century, but it was reserved to the genius and perseverance of Sebastian Erard, a celebrated piano-maker of Paris, to produce a harp, which, while fulfilling the high expectations of the musical world, attracted general notice by its commanding form, exquisite workmanship, and the chasteness and richness of its classical ornaments. This noble instrument was completed in 1810, and called Erard's Double-Action Harp, on account of its two mechanisms working together. It is tuned in the key of C flat. By fixing the pedals in the first groove the instrument is at once transposed into C natural; and by fixing them in the second groove, it is transposed another semitone higher, into the key of C sharp; the compass of the harp being thus from the double E below the bass to Einalltissimo. Since this time there has been no more improvement in the harp than there has been in the violin since Stradivarius. Erard of Paris and London, and Browne of New York (Geo. H. Buckwell successor), are the two best harp-makers in the world; and ac-

Fig. 260. — IRISH HARP OF THE  
ELEVENTH CENTURY.  
(College Museum, Dublin.)

cording to Boelisa, Aptommas, and other great masters of the harp in Europe, no European harp can give more complete satisfaction than Browne's splendid grand Gothic six octave and a half double-action, with the vibrating basses (Fig. 261). The harp has long been neglected for its noisy rival, the piano,

Fig. 261. — BROWNE'S AMERICAN HARP.

but it is remarkable that for the last ten years there is so marked revival of this beautiful instrument, that it is now seen in every music-store, and heard in all the fashionable houses. As an orchestral instrument it can no longer be dispensed with, for, beginning with Spontini in his famous opera, *The Vestal*, and Rossini in *William Tell*, it fills in the music of all great modern composers a place which nothing else can supplement. It does for a hundred other pieces what twilight does for scenery. While it blends harmoniously with all other instruments and voices, as the aroma of a flower-garden pervades the all-surrounding air, it never loses its own individuality. With the least noise, it sends forth the most melody. The highest and purest sphere of the harp, however, is in the drawing-room, where the beauty and association of its classic form, the living sympathy with which its tender and passionate vibrations blend with the female voice in its illimitable realm of song, have in all ages made it the mightiest ally of woman. The harp is a magical former of the voice. It softens all its tones, it

262) in the Greenland and other whale fisheries. The *gun-harpoon* is a weapon used for the same purpose but which is discharged from a swivel or gun, instead of being thrown by hand. This weapon is formed entirely of metal, and has a chain attached to it, to which the usual line is joined on, as in the former case. See **WHALE-FISHERY**.

**Harpooner**, the seaman in a whale-boat who uses the harpoon.

**Harpisichord**. See **PIANO-FORTE**.

**Harra**, a weight of Surat, about 787½ lbs. avoirdupois.

**Harrier**, a small hound for coursing hares.

**Harrisburg**. See **PENNSYLVANIA**.

**Harrisburg and Potomac R.R.** runs from Bowmansdale to Jacksonville, Pa., 25.13 m., with a branch to Philadelphia and Reading Coal and Iron Co.'s mines, 2 m. This Co., whose offices are at Boiling Springs, Pa., was chartered in 1870 and reorganized in 1871. The road was completed in 1878. It is proposed to extend the line from Harrisburg to Waynesboro', a distance of 60 m., and from the main line to Kettlestown, 30 m., with

Fig. 262. — HARPOONING A WHALE.

refines all its modulations; even the simplest accompaniment on this melodious instrument gives a charm and training to the voice to which the piano is an utter stranger.

**Harper, Harpist**, a player on the harps.

**Harpings**, in ship-building, are those planks or wales, forming the outer skin of a ship, which bend in towards the bow, and are fastened in the stern; they hold the timbers of the fore-and-aft cant-bodies till the ship is planked. They are made thicker than other parts of the wales, to encounter the great resistance offered by the water as the ship cuts through it. — *Cat-harpings* are minor ropes between the tops and mastheads, employed to draw the shrouds together and inwards towards the mast. They serve to tighten the shrouds, and to give freer play to the yards and sails when braced for on either tack.

**Harpings**, twisted gut-strings for harps.

**Harpoon, Harping-Iron**, an iron spear or javelin, shaped like a barbed arrow at one end, with a ring at the other through which a rope is run; used for the purpose of spearing whales (Fig.

several branches. *Financial statement*: Cap. stock, \$379,165.20; funded debt, \$507,200, consisting of 1st mortgage 7% 30-year bonds payable 1904.

**Harrisburg, Portsmouth, Mount Joy, and Lancaster R.R.** runs from Dillerville to Harrisburg, Pa., 35.54 m., with branch from Middletown to Columbia, Pa., 18.13 m.; total, 53.67 m. This Co., whose offices are in Philadelphia, was chartered in 1832, and leased in 1860 to the Pennsylvania R.R. Co. for 999 years, the lessees to pay all expenses, interest on the funded debt, and 7% on the cap. stock. *Financial statement*: Cap. stock, \$1,182,550; funded debt, \$700,000, consisting of 1st mortgage 7% 30-year bonds payable 1883.

**Harrow**, an agricultural implement, made in various shapes, but which, in its simplest form, consists of bars of wood or iron, fastened together transversely, either at right angles to each other or diagonally, with iron teeth projecting downwards from the points of intersection perpendicularly, or with a slight inclination. A *H.* with the bars set diagonally is the best, as their inclination to each other may be regulated in such a manner

that each tooth marks out a separate furrow; in consequence of which the implement performs its work more effectually than it would if the bars were disposed, as in the old *H.*, at right angles to each other. There is also an expanding harrow, in which the framework of bars is fastened together by loose pins, so that the teeth can be set closer together or farther apart, as the state of the soil may require. The *H.* is used in bringing land that has just been ploughed into a proper condition for the reception of the seed, by breaking the clods of earth into smaller fragments, tearing out the roots of the weeds or stubble, and pulverizing and mixing the soil. To effect this, and to render the surface tolerably smooth and even, the land is rolled and harrowed two or three times with different *H.*, a strong, heavy *H.* being used to break the furrows made by the plough, and lighter harrows, with the teeth set more closely together, in the final stages of the process.

**Harslet**, the pluck of a pig; the heart, liver, and lights.

**Hartall**, another name for orpiment in the Eastern markets.

**Hartford**, the capital and principal commercial city of Connecticut, situated on the Connecticut River, at the head of navigation, about 36 m. N. N. E. of New Haven, and 100 m. N. of New York, in lat. 41° 45' 59" N., lon. 72° 40' 45" W. It is a port of delivery, attached to the district of Middletown, and has a resident U. States surveyor of the port. The city is well built, and contains numerous public buildings, prominent among which is the new capitol, erected at a cost of \$2,500,000, and inaugurated in 1878. This splendid building is 295 feet 8 inches in length, 189 feet 4 inches in depth, and 257 feet 2 inches in height from ground to top of the crowning figure. The marble dome tower (still unfinished) rises in the centre of the building in a rectangular shape to the roof, and from there upward in the twelve-sided shape, with buttresses and columns on each of the twelve corners. Its diameter is 53 feet 4 inches. From roof to bottom of cone it is 75 feet 2 inches; the cone is 27 feet 4 inches in height; the lantern, 47 feet; globe and crowning figure, the "Genius of Connecticut," 15 feet. Four small towers, square in shape, rise with their finials 153 feet from the ground. *H.* carries on an extensive trade with the South and West, and has many flourishing manufactures, among which are the large establishment for the making of Colt's fire-arms, a large carpet company, one arms-manufacturing company, and several large iron-works and foundries. Its life and fire insurance business extends to every part of the country, and book-publishing is carried on to a considerable extent. Population, 40,000.

**Hartford**, a fire-insurance Co. located in Hartford, Conn., organized 1810. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$1,250,000; net surplus, \$861,556 09. Risks in force, \$188,039,953; premiums, \$2,162,188.

**Hartford, Providence, and Fishkill R.R.** runs from Providence, R. I., to Waterbury, Conn., 123.36 m. This Co., whose offices are in Hartford, Conn., leases the following lines: The Pawtuxet Valley R.R., from Hope, R. I., to River Point, R. I., 3.20 m.; the Rockville R.R., from Vernon, Conn., to Rockville, Conn., 4.80 m.; and the South Manchester R.R., from Manchester to South Manchester, Conn., 2.25 m. The Co. was formed by the consolidation of the N. Y. and Hartford R.R. Co., the Providence and Plainfield R.R. Co. in R. I., the Hartford and Providence R.R. Co., and the Fishkill Landing and Easterly R.R. Co. The coupons due

in 1858 not being paid, the whole property was taken possession of in that year by the trustees under the mortgage, and transferred to the New York and New England R.R. Co. on October 18, 1878. *Financial statement*: Cap. stock, common, \$1,537,939.98, and preferred 10%, \$500,000; total, \$2,037,939.98; funded debt, \$2,055,500, consisting of 1st mortgage 7% bonds extended to 1880.

**Hartshorn**. See AMMONIA.

**Harvest**, the time of reaping grain, or gathering in any crop.

**Harvesting-Machine**. See MOWER, and REAPER.

**Hasheesh** [Arabic], hemp, hay; also an intoxicating drug made of Indian hemp, which is sold in the East in the form of sweetmeats, paste, and tobacco.

**Hasp**, a fastening; a clasp that passes over a staple to be fastened by a padlock. — A spindle used in winding silk, thread, etc. — An agricultural implement used for scarifying the surface of grass-land.

**Hassock**, a footstool or cushion to kneel on; originally a rush-mat cushion, but now of more general signification.

**Hastener**, a metal kitchen-stand for keeping in the heat of the fire to the joint while cooking.

**Hat** [Fr. *chapeau*; Ger. *Hut*; It. *cappello*; Sp. *sombrero*], a covering for the head, well known to everybody. *H.* are made of various forms and sorts of material. They may, however, be divided into two great classes, *viz.* those felted, or made of fur, wool, silk, etc., and those made of straw. The manufacture of felted *H.* has been carried to perfection in the U. States, where it was introduced at an early date. The largest *H.* manufactories are located in New York, Danbury, Conn., and Newark, N. J. Straw *H.* are also made on a very extensive scale, chiefly in Massachusetts, Connecticut, and New York. For the year 1878 the value of *H.* exported from the U. States (mostly to the Dominion of Canada) were: for wool, fur, and silk *H.*, \$262,251; for straw *H.*, \$46,838.

*Imp. duty*: *H.*, bonnets, and hoods of straw, chip, grass, palm-leaf, willow, or other vegetable substance, or of hair, whalebone, or other material, n. o. p. f., 40 per cent. — *H.* braids, plaits, flats, laces, trimmings, tissues, willow sheets and squares, used for making or ornamenting the same, 30 per cent. — Fur *H.*, 35 per cent. — Leather *H.*, 40 per cent. — Silk *H.*, 60 per cent. — *H.* linings, according to material. — *H.* plush (see PLOSH).

*Manuf.* Felt *H.* are divided into many different grades, made principally of fur, the lower grades of wool, and in certain grades of a mixture of both materials. In the production of fur felts the material, after sorting and cleaning, is fed to a blowing-machine, which projects the particles against an upright revolving cone, made of wire gauze, and provided with an indrawing suction to cause adhesion of the particles. A light thin sack is thus formed, which is carefully wrapped in wet bagging and removed. Immersions in a hot bath and rolling make the sack or body ready for sizing, which is the process of shrinking and thickening the body to the required dimensions. This is accomplished by immersions in boiling water, with rolling and beating. The body is now stiffened, blocked into shape, pounced (*i. e.* sand-papered), and pressed. Next, the brim is trimmed to the desired width, and bound and (in the case of curl brimmed *H.*) flanged, when the *H.* is ready for lining. — *Wool H.* In the manufacture of wool *H.*, the process of forming and finishing the body is similar to that of making felt cloth, though less elaborate. Cheap grades of wool felts, designed principally for ladies' and children's wear, are made from felt cloth, stiffened and formed upon metal dies. These goods are known to the trade as *shoddy H.* — *Silk H.* are made of silk plush drawn over a very stiff but unfelted foundation. This foundation, according to the strength or the price intended, is made of calico, cambric, or other textile material, stiffened with shell lac and various other gums, and brought into shape by being worked over and around a block. The covering is a silk plush, woven with a kind of long velvet nap, or pile, on one surface, the best kinds of which are imported from France. The covering of the foundation with this plush is a work requiring much nicety, — to cut the plush so

as not to make much waste: to sew the pieces together after being cut; to give the foundation a coating of gum or cement; to fit the plush neatly on it; to cause the two to adhere by moisture and the pressure of a hot iron; to adjust the surplus plush carefully around the rim; and to brush and smooth the surface in such a way that the seams in the plush shall not be visible. — *Straw H.* are made of the straws of wheat, rye, oats, barley, Indian corn, etc., but those of wheat are most suitable. The Tuscan straw, from Leghorn and its neighborhood, is the finest and best of all; and this is the chief cause of the favor in which Leghorn hats and bonnets have long been held. Not only must the kind be selected, but individual straws are examined and sorted according to their length, colors, and thickness. Some straws are plaited whole, being merely pressed flat to facilitate the working. Others are split into four, six, or eight strips. This splitting is effected in a curious way. A wire, having four, six, or eight sharp edges, is thrust up the hollow of the straw so dexterously as to effect the required splitting, the strips being equal in width and smooth of edge. These slips, when softened in water, can be plaited as easily as whole straws. The straws (as many of them as to make one width of plait) are fastened at one end, and rapidly plaited one over another diagonally, the nimble fingers of the workpeople turning them over from right to left and from left to right. The kinds of plait are indefinitely numerous, depending on the kind of straw, on its thickness, on its being whole or split, on the number of straws plaited together, and on the kind of pattern produced by the mode of plaiting. Large numbers of women and children were employed at one time in the U. States in plaiting straw, but now almost all the braided used is imported. Straw *H* and bonnets are generally sewn in this country by the American Bosworth Straw-Sewing Machine, on which, when run by steam, 100 ordinary *H* can be made in a day. The *H* are then blocked, to give them the proper shape (see *HAT-BLOCK*), and then pressed by another machine, also of American invention, which smooths them ready for trimming at the rate of four a minute. The number of men who, in this country, are employed in the straw *H* manufacture is about 2,500; women, 15,000; youths under 16 years, 500. Grass, reeds, rushes, canes, broad fibres, or strips of almost every kind, can be plaited and made into *H*. in a somewhat similar way to that described above. See *FELT*, *HAT-BLOCK*, *HAT-PRESS*, etc.

**Hat-Block** is a form upon which the hat is finished. An important industry, developed in the last twenty-five years in connection with the production of straw hats, is the manufacture of plaster blocks made in the desired form, and to which pattern the hat is fitted and formed during the process of its manufacture. Previous to the inception of this industry, when the number of styles worn, and the changes made, were few, the hats were mostly sewed by measurement, and subsequently fitted and finished upon wooden forms. But the rapid development of straw hat manufacture in the New England States, and the numerous designs and frequent changes in styles, necessitated more rapid methods of duplication, which led to the invention of the *plaster of Paris hat block*. Duplications of the wooden block only were at first attempted, but the adaptability of plaster of Paris in the alteration of old and the production of new designs was soon discovered. The introduction of stamping machinery in the manufacture of buckram frames, silk, plush, velvet, felt, fur, and wool hats, and the invention and adoption of hydraulic presses in the manufacture of straw, fur, and wool hats, gave an additional impetus to this calling, on account of the necessary application of plaster of Paris in constructing the dies and other implements. The plaster-room of a hat-factory is of first importance, and the presiding genius a man of consequence, as upon his skill and taste in the adaptation of foreign novelties, and the production of new designs, depends much of the success of the establishment. From the knives with which the plaster models are cut and formed the artists engaged in this occupation have received the name of *whittlers*, — a name which but poorly describes a class of men in whom a rare combination of artist, inventor, and mechanic is essential to success. Prominent among the independent houses engaged in this business is that of Mr. A. Cumming, of New York,

to whom we are indebted for the above information.

**Hat-Body**, the whole body of an unfinished hat, as the *cone* from a forming-machine; a cloth hat before finishing, the *carcass* upon which plush is attached to make a silk hat, etc.

**Hat-Brush**, a soft brush for smoothing the nap of a hat.

**Hatch**, the covering of a hatchway, or opening, to the hold of a ship. — A railroad flood-gate or half-door. — A crib in the weir of a river to stop fish. — To breed; to produce from eggs by incubation or by artificial heat.

**Hatch-Boat**, a kind of half-decked fishing-boat; one which has a hatch or well for keeping fish.

**Hatchel**, a combing instrument for dressing flax. See *HACKLE*.

**Hatchet**, a chopper or cleaver. See *AXE*.

**Hatching**, a style of drawing or engraving in which the shading is performed by lines crossing at angles less than 90°.

**Hatching-Apparatus**, an artificial incubator for bringing forth chickens from eggs by steam or hot water.

**Hatchway**, an opening in the deck of a ship, or in the floors of warehouses or stores, through which merchandise is raised or lowered.

**Hat-Conformator**, a machine of French origin, by which the oval shape of the head is ascertained. It consists of a series of sliding arms, radially arranged in a frame, and carrying at their upper ends sharp points. When applied to the head, as is a hat, the arms are thrust outward by contact with the head, and assume a position corresponding to the exact conformation thereof. While thus held an impression is taken upon a slip of paper pressed upon the points. This paper is trimmed to the form delineated by the points, and becomes a pattern by which an adjustable block is set for use in reshaping the form of a finished hat. — *E. H. Knight*.

**Hat-Die**. Same as *HAT-MOULD*.

**Hat-Frame**, cross-bars of wood placed round three or four dozen hats in sending them out for home sale.

**Hat-Linings**, leather, silk, or other inside trimmings for hats.

**Hat-Money**. See *PRIMAGE*.

**Hat-Mould**, the die in which a hat or bonnet is formed or shaped by pressing.

**Hat-Press (Hydraulic)** is a machine for bringing a *bat* or *cone* of hat-making material to the form of a hat.

When and where hydraulic pressure was first used in the manufacture of hats is a matter of dispute, but it is on record that Hiram West, of Attleboro', Mass., procured a patent dated July 6, 1858, for improvements in hat-pressing machinery, the patent covering the use of the rubber diaphragm in connection with water. It was not for some years, however, that the invention became generally utilized, on account of the expense and crudeness of the machinery, and the lack of experience and general knowledge of hydrostatic principles of the men employed in that branch of manufacture. As in labor-saving appliances generally, the advance has been towards simplicity and strength of construction, ease, economy, and rapidity of operation. These requisites are perfectly combined in the machine represented in Fig. 263. A rubber diaphragm, A, is bolted

Fig. 263 — CUMMING'S HAND HYDRAULIC HAT-PRESS.

to the head, B, into which water is introduced from the tank C. The die is placed in the die-seat, D. When the hat is in place, the press is closed and locked against a pressure of 25 lbs. per sq. in., obtained by the upward movement of the side-lever, E, connected with the rock-shaft, G, in operating the crank movement, H, in the process of closing and opening the machine. Further pressure is obtained by means of the lever, M, connecting with the pump, P. This closing pressure is the principal feature of this machine.

**Hat-shag Maker**, a maker of imperial or silk plush for covering the bodies of hats.

**Hat-spring Maker**, a manufacturer of springs for light opera or closing-up hats.

**Hatter**, a maker or vender of hats.

**Hatter's-bow-string Maker**, a manufacturer of the fitted gut-cord used in bowing or felting the materials for beaver hats.

**Hatter's-Furrier**, a tradesman who prepares and keeps on sale the wool and different furs used for felting into hat-bodies.

**Hat-tip Maker**, a manufacturer of silk pieces for the lining of the crowns of hats.

**Hattock**, a Scotch name for a shock of corn containing 12 sheaves.

**Hat-varnish Maker**, a manufacturer of shel-lac varnishes, and other chemical preparations, for hatters.

**Haugh**, a little meadow.

**Haul**, to drag or pull.—A catch, as of fish, etc.—A ropemaker's term for about 400 threads of yarn warped off the winches with a slight turn in it, to be tarred.

**Hauler**, a workman engaged in drawing ore out of a mine.—A fisherman who pulls in a cast net to the shore.

**Haunch**, the hip or thigh; the hinder quarter of a small animal; sometimes applied to a joint of mutton or venison dressed.

**Hausser**. See **HAUSER**.

**Haut**, a measure at Bombay of 18½ inches; at Calcutta about 17½ inches.

**Hautboy**, a wild strawberry.—A musical wind instrument. See **OBOE**.

**Haute-Lice** [Fr.], tapestry hangings; an upright loom.

**Haute-Marée** [Fr.], high-water.

**Havana**. See **CUBA** (Scaports).

**Havana Tobacco**. See **TOBACCO**.

**Haven**, a port for shelter. See **HARBOR**.

**Haversack**, a soldier's knapsack; a gunner's case for ordnance.

**Havre**. See **FRANCE** (Scaports).

**Haw**, the berry of the hawthorn, used in Europe in cookery.

**Hawaiian Islands**, or **Sandwich Islands**, a rich, beautiful, and most interesting chain of islands in the North Pacific Ocean, forming the kingdom of Hawaii, extending from S. E. to N. W., in lat. 19° to 22° 15' N., lon. 151° 48' to 160° 20' W., discovered by Cook in 1778. They consist of 13 islands, 8 of which are inhabited: Hawaii (formerly Owhyhee), Maui, Oahu, Molokai, Lanai, Niihau, Kohoolau, and Kauai. The *H. I.* occupy a united area of 7,628 sq. m.; they are very mountainous, and appear to be chiefly of volcanic origin. Hawaii, the largest of the group, contains the two stupendous volcanic mountains, Mauna Loa, which is still in activity, and Mauna Kea, each rising to nearly 14,000 feet. The islanders are honorably distinguished among the Polynesian nations by the advances they have made in civilization; and particularly by their progress in manufactures, navigation, and commerce. Christianity was introduced by the American missionaries in 1820, and is now the religion of the state; schools have been established, churches have been built,

and the forms of religion are pretty well observed. European usages have become fashionable, and the costume of the better classes, women as well as men, closely resembles that of the Americans. The staple exports of the islands are sugar, molasses, sirup, coffee, goat-skins, sweet potatoes, wool, hides, salt, tallow, beef, pu-lu, arrow-root, whalebone, whale-oil, and tropical fruits. Agriculture has made marked progress during the few last years, but the means of subsistence are so easily procured, that the inhabitants have but few inducements, even did they not lack the industry and enterprise, to become extensive agriculturists. There are large tracts of good grazing land scattered throughout the islands, and the growth of cattle is a leading, perhaps the most profitable, branch of agricultural industry. There are also numerous sheep ranges, on which are tended about 12,000 sheep; but the business has not been encouraging. The eminently advantageous position of the *H. I.*, lying on the great route between America and China, invited at an early period the enterprise and capital of several European and American settlers, and led to the establishment of a somewhat active trade. They constitute a common centre between the three principal whaling-grounds of the Northern Pacific,—one on the equator, another near Japan, and a third towards the Behring Sea.

The principal port is Honolulu, on the S. side of the island of Oahu, in lat. 21° 18' 3" N., lon. 157° 55' W. Pop. 12,000, of whom about 4,000 are Englishmen, Americans, and other foreigners. The harbor, to which the place owes all its importance, has a narrow entrance, but it is easy of access at all times of the tide to vessels not drawing more than 18 feet water. The bar at its mouth being narrow, and composed of soft coral, it might easily be made accessible even for line-of-battle ships.

The foreign commerce of the *H. I.* for 1878 showed a considerable gain over that of previous years. The value of imports and exports for the 3 yrs. 1876-1878, was as follows:—

	Imports	Exports
1878.....	\$3,046,339	\$3,518,471
1877.....	2,428,000	2,676,202
1876.....	1,811,770	2,241,041

The foreign goods taken by the islands consist chiefly of machinery and lumber (which amount to \$650,000), clothing, hats, boots and shoes, dry goods, flour and grain, groceries and provisions, iron, steel, hardware, agricultural implements and tools, paints, oils, turpentine, spirits, wines, furniture, carriages, wagons, etc.

The commerce of the *H. I.* with the U. States for the 10 yrs. 1869-1878, was as follows:—

Years	Imports from the U. S.		Exports to the U. States.	Total Imports and Exports.
	Domestic.	Foreign.		
1869	706,462	86,665	1,208,085	2,001,212
1870	804,371	64,045	1,114,248	2,012,664
1871	840,385	43,730	1,153,154	2,037,269
1872	620,295	43,400	1,285,320	1,949,084
1873	654,103	43,088	1,316,270	2,013,461
1874	623,280	26,318	1,071,172	1,666,800
1875	655,174	40,130	1,227,191	1,922,555
1876	754,267	54,960	1,382,532	2,191,819
1877	1,206,912	163,520	2,031,763	4,402,225
1878	1,783,696	52,653	2,688,430	4,524,779

The value of the principal articles imported from the U. States for the year 1878 was as follows: Agricultural implements, \$17,227; horned cattle, \$2,800; horses, \$6,350; sheep, \$7,080; beer, \$3,405; books, etc., \$10,105; bread-tuffs, \$162,963; bricks, \$10,453; carriages, \$15,430; cordage, \$10,582; cotton goods, \$80,249; fancy articles, \$10,230; fruit, preserved in cans, \$9,338; gold and silver coin, \$100,250; jewelry, \$6,577; hats, \$21,193; hay, \$8,315; india-rubber goods, \$7,557; stoves, \$6,870; machinery and other manufactures of iron, \$453,080; leather, \$13,330; boots and shoes, \$35,416; saddlery, etc.,

\$18,257; matches, \$6,094; mineral oil, \$32,488; paper and stationery, \$18,107; bacon and hams, \$13,102; butter, \$11,703; pickled and cured fish, \$55,491; preserved meats, \$10,424; potatoes, \$9,667; rice, \$6,800; sewing-machines, \$3,681; whiskey, \$10,165; refined sugar, \$9,214; cigars, \$7,140; sailing vessels, \$51,950; wearing apparel, \$67,776; wood (lumber, etc.), \$184,225; household furniture and other manufactures of wood, \$91,761.

The total of English, German, and French goods shipped to the islands in 1878 was about \$670,000, or less than one third of what the U. States supplied. All European goods pay a duty of 10% ad valorem, while American produce enters the *H. I.* free, under the reciprocity treaty concluded with the U. States, and which took effect in 1877. The cultivation of cane and manufacture of sugar in the *H. I.* has received a great impetus from that treaty, and the product for 1878 was 33,431,458 lbs. against 25,575,965 lbs. for 1877. The number of sugar plantations had also increased from 40 in 1877 to 60 in 1878. But the limit of sugar production in this group must soon be reached, as nearly all the available sugar land has been taken up, which fact, combined with the scarcity of labor, must fix the limit of the annual production of sugar at about 25,000 tons, or 50,000,000 lbs. American shipping employed in the trade with the islands numbered 183 vessels, of 110,671 tons register in 1878, which is more than double the tonnage of all other nations engaged in trade with the islands. Four steamers are now engaged in the island coasting-trade, to which 2, now building in San Francisco, will soon be added.

Although the *H. I.* appear to be in a very prosperous condition, it is a curious fact that the native population has been rapidly and steadily decreasing, and does not now probably exceed a third part of its amount at the epoch of their discovery. The population in 1847 is said to have amounted to above 112,000; while the census taken in 1879 fixes the total population of the islands at 58,000, of which 10,500 are foreigners.

**Hawk**, a small quadrangular piece of board used by plasterers to hold a small quantity of plaster while at work. It is held by a handle at the bottom.

**Hawker**. It is not very easy to distinguish between hawkers and peddlers. Both are a sort of itinerant retail dealers, who carry about their wares from place to place; but the former are supposed to carry on business on a larger scale than the latter. They are generally required to take out licenses under the State laws.

**Hawk's-bill Turtle**, the *Chelone imbricata*, valued for its shell, which is employed for manufacturing purposes.

**Hawse-Block**, the wooden plug or stopper fitted into the hawse-hole when the ship is at sea.

**Hawse-Hole**, the hole in the bows of a ship through which the cable runs.

**Hawser**. See **CABLE**.

**Hay** [Fr. *foin*; Ger. *Heu*; It. *fieno*; Sp. *heno*], any kind of grass cut and dried for the food of cattle. The great object in preparing grass for hay is to preserve the green color of the grass as much as possible, and to have it juicy, fresh, and free from all sorts of mustiness. The hay and fodder crops, including the dried blades, shucks, and tops of Indian corn, as well as of the succulent corn plants, and other green forage, cultivated solely for *soiling*, or for drying into fodder, chopped straw, the haulm of beans, pease, potatoes, etc., which are by no means inconsiderable, are far the most valuable of any in the U. States. The culture of hay is principally confined to the Eastern, Middle, and Western States, from which the Southern markets are mainly supplied in the form of pressed packages or bales. The principal indigenous grasses which have been successfully cultivated in this country are the Kentucky blue grass, the red-top (herds-grass of Pennsylvania), the white clover, and the fowl-meadow (or bird-grass). Pre-eminent in extent of cultivation among our forage crops of foreign origin are the timothy (herds-grass of New England), and the common red clover.

The following table exhibits the production, acreage, and value of hay in the U. States for the year 1878:—

States.	Tons.	Acres.	Value.
Maine .....	1,138,000	1,264,444	\$14,225,000
New Hampshire .....	715,000	650,000	8,437,000
Vermont .....	1,050,000	1,071,428	10,605,000
Massachusetts .....	665,000	665,000	10,108,000
Rhode Island .....	120,000	116,505	2,280,000
Connecticut .....	580,000	527,272	10,875,000
New York .....	5,250,000	4,375,000	50,400,000
New Jersey .....	610,000	469,231	8,601,000
Pennsylvania .....	3,020,000	2,516,667	29,294,000
Delaware .....	40,000	36,363	560,000
Maryland .....	240,000	192,000	2,700,000
Virginia .....	260,000	200,000	2,860,000
North Carolina .....	126,000	93,333	1,218,420
South Carolina .....	21,500	20,283	307,450
Georgia .....	21,800	17,440	348,800
Florida .....	.....	.....	.....
Alabama .....	23,500	18,077	305,500
Mississippi .....	25,500	18,214	408,000
Louisiana .....	.....	.....	.....
Texas .....	75,000	60,000	806,250
Arkansas .....	20,000	14,286	260,000
Tennessee .....	152,000	116,923	1,744,960
West Virginia .....	290,000	223,077	2,465,000
Kentucky .....	320,000	246,154	3,120,000
Ohio .....	2,100,000	1,680,000	16,884,000
Michigan .....	1,160,000	878,788	9,976,000
Indiana .....	1,050,000	846,774	6,825,000
Illinois .....	3,936,000	2,460,000	23,104,320
Wisconsin .....	1,350,000	1,038,461	9,450,000
Minnesota .....	1,070,000	891,667	5,617,500
Iowa .....	2,550,000	1,961,538	12,112,500
Missouri .....	1,000,000	750,000	7,350,000
Kansas .....	1,155,000	700,000	4,042,500
Nebraska .....	475,000	327,586	1,733,750
California .....	560,000	622,222	8,400,000
Oregon .....	160,000	106,667	1,760,000
Nevada, Colorado, and the Territories .....	250,000	192,308	2,750,000
Total .....	31,629,300	25,367,708	\$271,934,950

Our exports of hay for the year 1878 (chiefly to the West Indies) amounted to 9,514 tons, valued at \$141,340.

**Hay-Band**, a rope made of twisted hay.

**Hay-Cock**, a pile or heap of hay in a field.

**Hay-Fork**, a pronged instrument for turning over hay, or lifting it from the cart to the rick.

**Hay-Knife**, a long, sharp cutting instrument for taking hay from a hay-rick.

**Haymaker**, an agricultural laborer; one who cuts grass and turns it over from time to time in the sun to be dried for hay.

**Haymaking-Machine**, a grass-cutting apparatus taking the place of the scythe.

**Hay-Market**, a place in a town whither hay is brought for sale.

**Hay-Rake**. See **RAKE**.

**Hay-Rick**, a pile or stack of hay.

**Hayti and San Domingo (Republics of)**. Hayti, also frequently called San Domingo, is one of the largest and most fertile of the West India Islands. It extends in length from E. to W. 390 m., and in breadth from 60 to 150 m., between lat. 17° 37' and 20° N., lon. 68° 20' and 74° 28' W. The country was formerly divided between the Spaniards and the French. The line of demarcation which separated these two divisions commenced on the S. side, from the Pedernales or Flint River, and extended in a waving direction to the river Massacre, on the N. side. The country to the W. of this line, which is of an extremely irregular figure and deeply penetrated by the Gulf of Gonaives, belonged to the French, and now forms the *Republic of Hayti*. The country on the E. side, by far the greatest portion—but also the most mountainous—of the island, belonged to the Spaniards, and now constitutes the *Republic of San Domingo*. A great part of the coast of this island is rocky and dangerous, affording but an imperfect

shelter to vessels overtaken by storms. Many of the shipping-places on the S. shore are nothing more than open bays, which lie exposed to the storms and hurricanes of the autumnal months. The harbor of San Domingo, formerly thought so commodious and secure, has become too shallow to admit vessels of large burden. There are, however, besides roadsteads and several small harbors, the bays of Neyba and Ocoa on this coast. Into the former flows the river Neyba, which receives vessels of 30 tons burden: its stream, before entering the ocean, divides itself into various channels, which, annually changing, confound the pilot and render the navigation difficult. Ocoa Bay is a large and convenient watering-place, with several small rivers falling into it. The entrance is two leagues across, and it gradually widens to nearly six. On the E. side of this bay is the safe and capacious port of Caldera. On the S. E. coast is the great Bay of Samana, which, in point of size and situation, is one of the most important on the island. From Cape Raffael, which forms the S. point of entrance into the Bay of Samana, to the opposite side of the island or peninsula of Samana, the distance is 18 m., which is closed in by bulwarks of rocks and sand, the entrance only being left clear, with a safe and deep channel between the shore of Samana and several detached islands. This bay is about 60 m. long, and is surrounded on every side by a fertile country, suited to all the purposes of trade. Within the compass of this bay whole fleets might ride at anchor in perfect security. The river Yuna, after being joined by the Cambu, and meandering through the rich plains of La Vega Real, falls into the Bay of Samana after a course of nearly 100 m. Bahia Ecossaise, or Scotch Bay, which is situated on the N. side of the peninsula of Samana, is a dangerous, rocky place. Thence to Puerto Plata the coast extends about 60 m. in a N. W. direction, and in this square stands Balsama Bay, which has only 14 feet depth of water, and is of difficult navigation. The entrance of the harbor of Puerto Plata is narrow, but safe, and the neighborhood is rich in every species of timber-trees. There are several other small harbors and bays on this side of the island, but the coast is in general rocky and dangerous. — *Soil and Surface.* A country of such magnitude as Hayti, containing mountains of great height, with valleys of corresponding extent, necessarily comprises great variety of soil. In general, however, it is fertile in the highest degree, being everywhere drained by copious streams, and yielding in abundance every species of vegetable produce which can minister either to the luxury or comfort of man. The soil consists principally of a rich clay, sometimes mixed with gravel, lying on a substratum of rock. That part of the island formerly occupied by the French is mountainous, but fertile and well wooded, and containing mines both of silver and iron. The Spanish or San Domingo part of the island is mountainous in many parts; while in other parts the country is spread out into extensive plains. These are generally in a state of nature, covered with herbage, or with

woods of immense growth and the most luxuriant foliage. The mountains intersect the island in two principal chains from E. to W. From these secondary and partial ridges diverge irregularly in different directions, forming beautiful and fertile valleys, with numerous streams. The highest mountains of the interior, particularly those of Cibao, rise to the height of 7,200 feet above sea-level. To the N. of Port-au-Prince is the valley called Vega Real, or Royal Plain, which is by far the largest and finest in the island. Westwards it extends to the old French line of demarcation, and in this part it is drained by the river Yocki; to the E., where the river Yuna flows for the space of 50 m., it projects to the head of the Bay of Samana, and is drained by numerous smaller streams which cross it in various directions. This valley may be said to extend in length about 140 m., and in breadth from 20 to 30. Other plains also, of

Fig. 264. — *GYNERIUM ARGENTEUM*.

less extent but of equal fertility, and of easy access, are everywhere found interspersed among the mountainous tracts. Eastward from Port-au-Prince are those immense plains called *Las Lunas*, which stretch out to a vast extent on a dead level. They are covered with herbage, and the eye wanders unobstructed over the wide expanse of waving grass, intersected with the *Gynerium argenteum*, or pampas grass (Fig. 264), and occasionally diversified by natural clumps of shrubs. These plains occupy almost one sixth part of the island, extending nearly to its eastern coast, being a distance of more than 90 miles, by about 30 wide. They form an immense natural meadow, covered with pasture for vast herds of cattle which belong to more than 100 different owners. — *Climate.* Hayti has a hot moist climate, but the heat is mitigated by the regularity of the sea-breeze, and by the contiguity

of the mountains. In the plains the thermometer rises to 96°, sometimes to 99°, but in the mountainous tracts it seldom rises above 78°. In the most elevated part a fire is frequently necessary. In those situations meat may be kept for several days, and in the morning hoar-frost is frequent. The seasons, as in tropical countries, are divided into the wet and the dry. The rains are periodical, and are heaviest in May and June, when the rivers, which at other times scarcely supply water for a continued stream, overflow their banks, and, with an impetuous torrent, sweep over the neighboring plains. The climate of Hayti is unhealthy to Europeans, owing to the violent heats and heavy rains; and all metals, however bright their original polish, soon contract a tarnished appearance. This is more observable on the sea-coast, which is also more unhealthy than the interior of the island. Hurricanes are not frequent, but in the southern parts of the island violent gales of wind, generally preceded by a closeness and sultriness in the atmosphere, frequently occur. These, however, are not attended with such fatal effects as the hurricanes in the Windward Islands. — *Vegetable Productions.* The fertile soil of *H.* is distinguished by the variety of its vegetable productions, many of which are rare and valuable. The mahogany-tree grows to a great size, and is of very fine quality. The manchineel-tree affords a beautiful species of wood, richly veined like marble, and susceptible of the finest polish. Several species of dye-woods are produced in the forests. There is a tree called the jagua, the fruit of which is accounted a delicacy by the natives; and of which the juice, as clear as water, makes a stain on linen which is indelible. Different kinds of gnaiaum are found, as also of several other woods with the same properties, which grow unnoticed and nameless in those unexplored forests. The sideroxylon, or iron-wood, is abundant; and the oak also, which differs in appearance from the European oak, frequently furnishes beams of from 60 to 70 feet in length. On the N. side of the island are extensive forests of pine, which is much used for the purposes of ship-building; and Brazil-wood is found on many parts of the coast. The satin-wood of this island is heavier than that of the East Indies, and it takes so fine a polish that it does not require to be varnished. The cotton-tree is the largest of all the vegetable productions, and is formed into the lightest and most capacious canoes. Every variety of the palm-tree is found in the woods, of which they form a principal ornament. In the congenial soil of this fertile island the sugar-cane, cotton, and coffee-plants grow in the greatest luxuriance. There is also the calabash, the fruit of which serves as a substitute for earthenware; the plantain, the staff of life in the West Indies; vanilla, which is found indigenous in the unfrequented woods; quassia, or simarouba, which is a tall and stately plant, waving gracefully in the wind; sarsaparilla, indigo, tobacco, turmeric, ginger, and rice-plants. Of the fruits and nutritive roots of Hayti there may be enumerated the choux caraib, or Indian kale, with a variety of other vegetables that come under the same denomination; the avocado, or vegetable marrow, the melon, sapa-dillo, guava, pine-apple, bread, and jack-fruit, mango, nuts, rose-apple, plums, etc., of many different species. Flowers in endless variety and splendor adorn the wild scenery of the woods and exhale their fragrance in the desert air. — *Minerals.* The mineral products are various and rich, and include gold, platina, silver, quicksilver, copper, iron, tin, sulphur, manganese, antimony, rock-salt, bitumen, jasper, marble, opal, lazulite,

chalcedony, etc. The gold mines of the Chiboa Mountains, which in the 16th century were very productive, have been abandoned, and at the present day gold is obtained only from the washings in the northern rivers. None of the mines, indeed, are successfully worked, and hence these sources of wealth are reserved for the industry of future generations.

#### REPUBLIC OF HAYTI.

This republic, which embraces the western portion of the island, with an estimated area of 10,204 sq. m., is governed under a constitution proclaimed June 14, 1867. By its terms the legislative power rests in a National Assembly, divided into two chambers, respectively called the Senate and the House of Commons. The latter is elected by the direct vote of all male citizens for the term of three years, while the members of the Senate are nominated for two years by the House of Commons from a list presented by the electoral colleges. The executive power is in the hands of a President, who, according to the Constitution, must be elected by the people, but in recent years has generally been chosen by the united Senate and House of Commons, sitting in National Assembly, and in some instances by the troops, and by delegates of parties acting as representatives of the people. The nominal term of office of the President is four years; however, it is generally cut short by insurrections. — The public revenue and expenditure are known only by estimates, long-continued civil war having brought extreme disorder into the finances of the republic. It was reported that the receipts from customs, chief source of revenue, amounted to \$839,000 in the year 1878. The total public revenue is calculated to have amounted in recent years to about \$4,500,000, and the expenditure to \$7,000,000.

There is a large floating debt, consisting chiefly of paper money issued by successive governments, the greater mass enormously depreciated by frequent repudiation, and by forgery on a vast scale. There is also a foreign debt, consisting of a loan of 11,949,840 francs, or \$2,389,968, contracted at Paris in 1825, and of other liabilities incurred towards France, the total amounting to 32,049,840 francs, or \$6,409,968. No interest has for years been paid on this debt. Nevertheless, the government issued in June, 1875, with partial success, a new foreign loan of \$3,453,000 francs; or \$16,690,600, through the house of Marcuard & Co., Paris, the avowed object being to extinguish the old debt, both home and foreign, and to employ the remainder for the construction of two lines of railway.

A census of the population does not exist; the inhabitants, the moiety of whom are negroes, and the rest French-speaking mulattoes, with very few of European descent, are calculated by the best authorities to number about 572,000, while official estimates give them at 800,000. The capital is Port-au-Prince.

The commercial intercourse of the republic is chiefly with the U. States and Great Britain, the former contributing about 55 per cent and the latter 30 per cent to the aggregate imports and exports. The total annual imports in the 4 years from 1875 to 1878 averaged \$7,000,000, and the exports \$8,000,000. The principal articles exported are coffee, mahogany, and log-wood.

There is no report of the exact value of the commercial intercourse of the republic with the U. States in the "Annual Statement" published by the Department of the Treasury, which throws Hayti together with San Domingo. But as the population of the latter State is only about 1/3 that of Hayti, an estimate may be made of the respective distribution of exports and imports during the 20 years from 1859 to 1878, given in the following table: —

Years.	Imports from the U. States.		Exports to the U. States.	Total Imports and Exports.
	Domestic.	Foreign.		
1859....	\$2,274,473	\$230,079	\$2,859,636	\$5,364,188
1860....	2,597,959	245,023	2,345,821	5,188,803
1861....	2,418,664	187,994	1,926,693	4,533,351
1862....	3,088,108	191,731	1,910,922	5,190,761
1863....	4,106,868	362,208	1,878,337	6,347,408
1864....	4,272,864	312,132	2,032,712	6,617,708
1865....	6,228,684	406,226	1,522,965	8,157,875
1866....	3,596,735	229,798	1,239,201	5,065,729
1867....	2,405,498	348,413	1,022,079	3,775,990
1868....	3,021,093	301,710	843,450	4,166,253
1869....	1,349,438	129,462	729,632	2,208,532
1870....	2,617,633	183,700	979,655	3,780,988
1871....	2,791,057	173,949	1,065,676	4,020,681
1872....	3,326,747	244,232	1,517,951	5,088,930
1873....	4,854,246	416,997	2,260,425	7,531,668
1874....	4,730,339	201,401	1,933,177	6,914,917
1875....	5,350,237	123,372	2,548,339	8,021,998
1876....	5,428,583	146,552	3,481,562	9,056,697
1877....	4,513,597	107,584	3,864,418	8,485,599
1878....	4,307,432	88,922	4,174,924	9,071,278
Total.	\$78,880,255	\$4,631,475	\$40,127,624	\$118,539,354

The value of the principal articles imported from and exported to the U. States by the Republic of Hayti and San Domingo was as follows: *Imports*: Books, etc., \$10,798; bread-stuffs (chiefly wheat flour), \$719,113; candles, \$13,717; carriages, \$17,695; cotton goods, \$304,814; drugs, etc., \$11,587; gold and silver coin, \$67,213; iron manuf., \$94,056; matches, \$8,341; mineral oil, \$80,723; paints, \$6,747; paper and stationery, \$6,224; bacon and hams, \$38,716; salted beef, \$49,412; butter, \$56,594; cheese, \$15,437; fish (dried and pickled), \$790,592; lard, \$117,302; pork, \$905,251; sewing-machines, \$5,007; soap, \$268,526; refined sugar, \$71,064; leaf tobacco, \$37,322; trunks, \$13,377; wood (boards, deals, etc.), \$150,787; wood (household furniture and other manuf. of), \$55,496. *Exports*: Drugs, dyes, etc., \$24,858; cocoa, \$17,249; coffee (12,813,113 lbs.), \$1,891,207; cotton (raw), \$45,493; dye-woods in sticks, \$795,605; silver coin (American), \$769,255; brown sugar, \$20,510.

*Money, Weights, and Measures.* The standard of money is the *Piastre*, or dollar = about \$1. French gold and silver coins are in current use. The weights and measures in use are those of France.

*Regulations as to Trade.* It is enacted that all persons exercising any trade or profession, excepting that of cultivating the soil, must be provided with a patent or license to carry on such trade or profession; that all strangers admitted as merchants into the republic must, in the first place, procure the permission of the president to take out a patent, which, when obtained, only authorizes them, under heavy penalties, to carry on a wholesale business, not with each other, but with the Haytians, in the open ports, which are Port-au-Prince, Gonaïves, Cap Haïtien, Jacmel, Aux-Cayes, and Jérémie. The minimum quantities of goods that may be sold are fixed by the same law. The Haytian consignee may be also a retailer, on taking out a correspondent patent.

*Seaports.* Of the ports above enumerated the principal are: — *Aux Cayes*, or *Les Cayes*, on the S. coast of the island, 92 m. W. S. W. of Port-au-Prince. The city is generally reputed one of the most progressive in the island, and is the capital of the southern peninsula of Hayti; the best irrigated and most fertile province in the republic. Here, as in the other ports, the U. States holds the first commercial rank. The chief imports from the U. States are provisions and cotton goods. Pop. 10,000.

*Cape Haytien*, formerly *Cape Français*, on the N. coast, in lat. 19° 40' N., lon. 69° 54' W. It has the safest harbor of the island, and carries on a considerable trade, chiefly with the U. States. Pop. 10,000.

*Gonaïves*, on the gulf of that name, about 55 m. N. W. of Port-au-Prince, now exhibits scarcely the shadow of its former commerce. Its exports consist chiefly of coffee, which is of the very best quality, and commands the highest price. Hence it is that vessels which cannot make up their cargoes of coffee at Port-au-Prince touch at this port for such quantities as they can obtain. Pop. 8,000.

*Port-au-Prince*, the capital and chief commercial port of Hayti. The light-house on Lamentin Point is visible for 9 m. in lat. 18° 33' 35" N., lon. 72° 25' 12" W. It is situated on the W. coast of the island, at the bottom of a large and deep gulf. It is partially fortified, the harbor being protected by a battery on a small island at a little distance from the shore. The country round is low and marshy; and the heat in the summer months being excessive, the climate is then exceedingly unhealthy. The buildings are principally of wood, and seldom exceed 2 stories in height. The entrance to the harbor is between White Island and the S. shore. The depth of water varies from about 18 feet at ebb to about 21 feet at full tide. It is customary, but not compulsory, to employ a pilot in entering the harbor. Pilots are always on the lookout. Ships moor, head and stern, at from 100 to 500 yards from shore; loading and unloading by means of boats, as there are neither docks nor quays to assist these operations. The harbor is perfectly safe except during hurricanes, which may be expected from August to November. The bay of Port-au-Prince is wellnigh blocked up to the northward by numerous shoals and islets, which protect the anchorage. Pop. 35,000.

#### REPUBLIC OF SAN DOMINGO.

(*República Dominicana*.)

This republic, which embraces the eastern part of the island, with an estimated area of 18,045 square miles, is governed under a constitution proclaimed November 14, 1865. By its terms the legislative power is vested in a National Congress of two houses, called the Consejo conservador and the Tribunal; the first consisting of 12, and the second of 15 members. The members of both Houses are chosen in indirect election, with restricted suffrage, for the term of 4 years. But the powers of the National Congress only embrace the general affairs of the Republic; and the individual states, five in number, have separate legislatures. The executive power is vested in a president, chosen in indirect election for the term of 4 years. Constant insurrections have allowed very few presidents to serve the full term of office. The public revenue is about \$900,000 with an expenditure to the same amount. The revenue is mainly derived from customs duties, which average 40 per cent, while a large part of the annual expenditure is for

the maintenance of a standing army. Besides a large internal debt, of unknown amount, San Domingo has a foreign debt contracted at the London Stock Exchange in 1869. The debt, to the nominal amount of £757,700 (\$3,788,500) at 6 per cent, was issued at the price of 80; but it was stated officially that the government had actually received only between £38,000 and £50,000 from the contractors for the loan.

The republic is divided into the five provinces, or states, mutually independent, of San Domingo, Azua de Compostela, Santa Cruz del Seybo, Santiago de los Caballeros, and Concepción de la Vega. Pop. about 250,000, or 14 to the sq. m. The pop., like that of the neighboring Hayti, is composed mainly of negroes and mulattoes, but the whites, or European-descended inhabitants, are comparatively numerous, and owing to their influence the Spanish language is the prevailing dialect. The capital of the republic is the city of San Domingo, founded in 1494.

The commerce of the republic is small, owing in part to customs duties of a prohibitory character. The principal articles of export are, tobacco, coffee, dye-woods, and sugar. In 1878 the value of the imports amounted to \$1,963,046, and of the exports to \$1,678,911. (For the commercial intercourse of San Domingo with the U. States, see page .)

*Money, Weights, and Measures* are those of Spain; but the French metrical system is coming in use.

*Seaports.* The chief seats of commerce are San Domingo City, Porto Plata, and Samana, a small town on the peninsula of the same name (see page .). The city of San Domingo is situated at the mouth of the Ozama, on the S. coast, in lat. 18½° N. and lon. 70° W., and is the oldest European settlement in the New World. The town is defended by substantial fortifications. The cathedral is more than three centuries old. The harbor is capacious, but, owing to a bar at its mouth, vessels drawing above 13 feet of water are obliged to anchor in the open roadstead. Pop. 15,000.

**Hazel-Nut** [*Fr. noisette, aveline*; *Ger. Haselnuss*, *It. noccinola, avelina*; *Port. avelina*; *Sp. avellana*], the edible nut of *Corylus avellana*, a small under-wood, which is found growing wild in the forests of all parts of temperate Europe, and much resembles *C. americana*, which grows in thickets and borders of fields throughout the U. States. Hazel-nuts yield, on pressure, about half their weight of a bland fixed oil, often called *nut-oil* in England, the hazel-nut being popularly known by the term *nut* alone. But in France and in Germany it is walnut-oil which is usually called *nut-oil*. Hazel-nut oil has drying properties, and is much used by painters; it is also used by perfumers as a basis with which to mix expensive fragrant oils; and it has been employed medicinally in coughs. The wood of the hazel, although seldom large enough for the purposes of the carpenter, is very tough and flexible, and hazel-rods are therefore much used in Europe for making crates, hurdles, hoops for small barrels, etc. The thicker stems of hazel are used for making charcoal, which is in great request for forges, is much esteemed for the manufacture of gunpowder, and is the kind preferred by artists for crayons. Most of the cultivated varieties of the hazel-nut are known by the names of *rob-nuts* and *filberts*, the former generally of a roundish form, the latter characterized by the greater elongation and laciniation of the fruit-cup. The *Red Filbert*, or *Lambert's Nut*, is remarkable for having the pellicle which surrounds the kernel of a crimson-red color. Hazels are imported from Spain, Smyrna, Sicily, and other places. They are used in this country exclusively for the table and confectionery. *Imp. duty* 3 cts. per lb.

**Head**, the principal, chief, upper, or foremost part of a thing; the top of extremity of a thing, especially when larger than the other part or parts; as, the *head* of a mast, of a spear, cabbage, nail, cane, etc. — The fore or front part, or the place where the head should go; as, the *head* of a bed, the *head* (or hood) of a carriage. — A chief; a principal person of any organized body; a leader. — A bundle of flax measuring about 2 feet in length, and weighing a few pounds; in the North of Europe 18 head of hemp or flax are about 1

cwt. — The fore extremity of a ship. It generally means the cutwater, which is adorned with a figure. *By the head*, implies that the ship's head is depressed in the water. *Head sails, head yards*, are the sails and yards in the fore part of the ship.

**Head-Band**, a bookbinder's material of narrow silk or other substance, sold in pieces of a certain number of yards. It is used in fine bindings as a finish to the top and bottom of the sheets inside the back.

**Head-Dress**, a cap, feathers, or any ornament worn on the head by females.

**Header**, a cooper who closes casks. — A workman who heads nails or pins. — A brick with a short face in front.

**Head-Fast**, a rope to secure a ship's bows to the wharf or shore.

**Head-Gear**, the bridle of a horse; the headstall and bit.

**Headings**, pieces of wood suited for closing sugar hogsheads, and other casks of merchandise. Bangor and Portland are the principal depots for their sale.

**Head-Light**, a light, usually an oil-lamp, carried at the front end of a locomotive, to illuminate the way and act as a signal.

**Head-Lines**, in printing, lines conspicuously displayed at the top of a page, or to a chapter, which are set in small capitals. — In navigation, ropes next the yards.

**Head-Man**, a principal workman.

**Head-Matter**, spermaceti in its natural crude state, as taken from the cavity in the large head of the sperm whale, *Physeter catodon*.

**Head-Nets**, caps or coverings for the head, worn by ladies. They are made of human hair, silk, glazed and polished thread, etc., netted in open meshes.

**Head-Rope**, that part of a bolt-rope fastened to a sail.

**Headstall**, the part of a horse's bridle which goes over the head.

**Head-Stocks**, the frames which support the centres of a lathe; viz., the mandril-frame and the poppet-head, or back centre-frame; also, the framings used for supporting the gudgeons of a wheel.

**Head-Stone**, the chief or principal stone in a foundation; the corner-stone. — The stone placed at the head of a grave.

**Head-Valve**, the delivering valve of a steam-engine.

**Headway**, the progress made by a ship or boat in the water. — A passage in a mine driven in the direction of the layer of coal.

**Head-Workman**, the principal operative in an establishment.

**Healing**, the covering a roof with tin, slates, etc.

**Healds**, the harness for guiding the warp-threads in a weaver's loom.

**Heap**, a pile, as of stones, dung, etc.

**Heap-Measure**, as described in the New York State Law, is a measure in which the commodity is heaped up above the sides in the form of a cone, the outside, or outer edge of the measure being the limit of the base of the cone, and the cone to be as high as the article will admit.

**Hearse**, a funeral carriage for conveying a corpse to be buried.

**Hearse-Cloth**, a coffin pall.

**Heart**, the chief part; the inner part of anything; the middle part, or interior; the vital part; the centre of action or motion. The heart of wood is the solid portion divested of sap-wood, or alburnum.

**Hearth**, a floor for a fire.

**Hearth-Broom**, a sweeping brush for the hearth or grates.

**Hearth-Rug**, an ornamental rug or carpet-work laid before a fire-hearth.

**Heart-Wheel, Heart-Cam**, the name given to a well-known mechanical contrivance for converting a circular motion into an alternating rectilinear one, which is generally adopted in the machinery of cotton-mills. It consists of an ellipse turned either on an axle, or by means of a winch and handle in one of its foci, or its centre, or whose edge a movable point or circle presses; the latter receives an alternating motion from the circumference of the ellipse, which in its motion presses it to different distances from the centre of motion. The practical disadvantages of this contrivance are, the inequality of pressure and of moving force which will be required at different parts of the rotation of the ellipse, and the consequent wearing of some parts of it before the remainder.

**Heat, Caloric**. The vast range of scientific investigations concerning this subject belongs to physics and chemistry; but the practical results to which these investigations have led exert a direct influence on all such manufacturing operations as smelting, forging, welding, melting, distilling, gas-making, etc.; and upon the evolution of power in steam and hot-air engines. Temperature, dilatation, expansion, vaporization, conduction, radiation, — these and other terms serve to denote the several modes in which heat makes its effects manifest. Much useful information, in connection with these heat-producing and heat-produced effects, will be found in this work under the heads COMBUSTION, EBULLITION, EVAPORATION, EXPANSION, REFRIGERATION, STOVE and HEATING APPARATUS, etc.

*Degrees of Heat* See THERMOMETER and PYROMETER.

*Mechanical Equivalent of Heat*. An immense stride has been made in the philosophy of manufactures by the determination of the mechanical equivalent of heat, chiefly through the patient and masterly experiments of Dr. Joule. Heat, according to the modern view, is convertible into mechanical force or energy; and a given quantity of the one is found to be equal to, or productive of, a given quantity of the other. This equation has been ascertained by measuring the friction of solids, liquids, and gases under various conditions, as productive of heat, and, conversely, by measuring the mechanical work effected by a given amount of cooling. The unit of power is taken to mean the force which will lift 1 lb. 1 foot high; this is called a *foot-pound*. The unit of heat employed is that quantity of heat which will raise 1 lb. of water 1° F. in temperature. Now it is found that about 772 of the former are equivalent to 1 of the latter; that is, an amount of heat which would increase by 1° F. the temperature of 1 lb. of water would, under altered arrangements, lift a weight of 772 lbs. 1 foot high. This ratio, which receives the name of *Joule's equivalent*, is becoming very important in settling the theory of the hot-air engine, steam-engine, and other machines worked through the instrumentality of heat.

The following table shows the heating power of various combustible substances, exhibiting the utmost quantity of water evaporated by the given weights, and the smallest quantity of air capable of producing total combustion, according to Dr. Ure: —

Species of combustible.	Pounds of water which a pound can heat from 0° to 212°	Pounds of boiling water evaporated by 1 pound.	Weight of atmospheric air at 32° to burn 1 pound.
			Least quan.
Perfectly dry wood.....	35.00	6.36	5.96

**Heater**, any contrivance used to impart heat; a stove; a furnace, etc. See STOVE AND HEATING APPARATUS. — A triangular mass of iron, which is heated in the fire, and put into a box-iron to smooth cloth.

**Heave**, in nautical phrase, to employ force to move great weights by the lever, etc.; as to *heave up* the anchor by the capstan or windlass; to *heave down* the ship, or pull her over on one side to get at a leak; also to heave taught (tight), or turn the capstan till the rope or chain applied to it becomes tight.

**Heaver**, a stevedore or 'long-shore man. — A short wooden bar tapering at each end, used as a purchase or prising lever.

**Heavy**, weighty; ponderous.

**Heavy-laden**, vessel sitting deep in the water, which has a full cargo; vehicle carrying a large burthen.

**Heavy Spar**. See BARYTES.

**Heck**, a rack or crib for cattle, etc., to feed at.

— A contrivance of lattice-work for catching fish.

— A weaving apparatus through which the threads of warps pass from the bobbins to the warping-mill, and by means of which they are separated into sets for the heddles.

**Heckle**, a flax-dresser's comb or machine for cleaning and subdividing the fibre. See FLAX (MANUFACTURE OF).

**Hectare**. See ARE.

**Hecto**, a Greek prefix to French weights and measures, signifying a hundred times greater.

**Hectogramme**. See GRAMME.

**Hectolitre**, 100 litres, a French liquid and dry measure of capacity = 26.4178 gallons, or 2.8378 bushels.

**Hectomètre**. See MÈTRE.

**Hectostere**. See STERE.

**Heddle**, in weaving, one of the sets of parallel double threads which are arranged in sets, and, with their mounting, compose the harness employed to guide the warp threads to the lathe or batten; heald. — *Heddle-eye* is the eye or loop formed in each heddle to receive a warp thread.

**Hedge**, a fence of bushes or living plants; a bank or mound.

**Hedgehog**, a dredging-machine, employed in harbor works and rivers for removing shoals formed by accumulated mud or silt. — A small insectivorous quadruped, the *Erinaceus Europæus*, sometimes kept in bake-houses and kitchens to eat up cockroaches.

**Hedger**, a workman who has the charge of repairing hedges and ditches.

**Hedge-Scissors**, large shears for trimming quick-set hedges.

**Heel**, the hinder part of the sole of a boot or shoe, built up of pieces of leather. In shoe-manufactories heels are made with great rapidity by a series of separate machines which cut out and compress lifts to shape; fasten together the several lifts which compose a heel; trim or burnish the edges of the lifts (Fig. 265) so as to bring the heel to symmetrical shape; cut down the front, which is called *breasting*; cut the seat for the heel; lay on and secure the *rands*; fasten the heels to the boots; dress the heel-faces; polish the heels; and give the stitch-marks along the edge on the upper surface. — The after extremity of a ship's keel. — A nautical term for the lower end of anything, as of a rafter, a tool, a mast, boom, stern-post, etc. *To heel over*, to incline to one side.

**Heel-Ball**, a hard wax, or polishing substance, used by shoemakers to give a shining black surface to the sole edges of new boots or shoes.

**Heeling**, in navigation, a vessel leaning over. — Putting new heel-pieces to boots.

**Heel-Tip**, an iron plate or protection for the heels of boots and shoes.

**Heer**, a yarn measure; a heer of 24 cuts, or 240 threads, is 600 yards.

**Heerabole**, an Indian name for myrrh.

**Heifer**, a young cow.

**Helaha**, a tree in the Pacific islands, the seed of which is used to make necklaces.

**Helbeh**, an agricultural seed with a somewhat bitter taste, whose flour is mixed with dourah, or dhurra, by the laborers of Egypt.

**Helicograph**, an instrument for describing helices.

**Heligoland**, a small island in the North Sea, belonging to Great Britain, situate opposite to,

Fig. 265. — HEEL-TRIMMER.

and about 40 m. from, the mouth of the Elbe, in lon. 7° 51' E., lat. 54° 11' N. Including Sandy Island, it is about 2½ m. in circumference. It is the most renowned of the North Sea bathing-places, and the inhabitants (about 2,000) live by fishing and by letting lodgings. Steamboats run between Heligoland and Hamburg.

**Heliography**, the name originally given by Nicéphore Niépce to the art of taking sun-pictures. See PHOTOGRAPHY.

**Heliometer**, a kind of telescope, with two object-glasses, for measuring the diameter of the sun, moon, and planets.

**Helioscope**, a telescope for viewing the sun through colored glass without injury to the eyes.

**Heliostat**, a philosophical instrument for reflecting an image of the sun into the telescope of a theodolite at a distant station: a train of clock-work so rotates a mirror that on being once adjusted it follows the sun's motion, requiring only winding and occasional adjustment to give a constant vivid station-signal when the sun shines.

**Heliotrope**, green quartz with blood-red spots and veins. See **BLOODSTONE**. — A popular plant, also called turnsole, *Heliotropium Peruvianum*, having a delicious odor, not unlike that of new hay. — An optical instrument used to reflect a ray of light to a distant station.

**Hellebore Root**, the rhizomes of several species of European herbs, of the genus *Helleborus* or *Veratrum*. The most important species is *H. niger*, the black hellebore, so called from the color of its roots, which are imported in bags and barrels from Hamburg, and are used in medicine as a drastic purgative. *Imp.* free.

**Heliotype**. See **PHOTO-ENGRAVING**.

**Hellenotype**, in photography, a picture in which two finished photographs are used. One is taken very light, the paper made translucent by varnish, tinted on the back, and laid upon the stronger print, so that there is a combination of effects. — *E. H. Knight*.

**Hellier**, a slater or tiler.

**Helm**, the tiller of a ship, but also applied to the collective apparatus or machinery by which a vessel is steered, comprising the rudder, wheel, tiller-ropes, etc. To put the helm *a-starboard*, is to put the tiller to the right side; *a-port*, to the left side; *up*, to the weather side; *down*, to the lee side.

**Helmet**, a horse-soldier's head-piece; a protection for the head. — The upper part of a retort.

**Helmet-Shell**, a common name for shells of the genus *Cassides*, which are used for cutting cameos from; the principal being *Cassis cornuta*, *C. rufa*, and *C. tuberosa*.

**Helmsman**, the man at the wheel who steers a ship.

**Help**, aid; assistance. — A hired servant.

**Helpmate**, an assistant.

**Helve**, the long handle of a tool.

**Helve-Hammer**, a large ponderous blacksmith's hammer for manufacturing wrought iron.

**Hem**, the border of a garment doubled and sewed over, to strengthen it and prevent the raveling of the threads.

**Hemadrometer**, an instrument for measuring the velocity of the blood in the arteries.

**Hematin**, the coloring principle of logwood.

**Hematite**, a rich ore of iron, of which there are several varieties, the red, black, purple, brown, etc.

**Hematosin**, the red coloring matter of blood; in its dried state it is sold for making Prussian blue.

**Hemi**, a Greek word used as a prefix, signifying half.

**Hemlock**, the fresh and dried leaf of the wild herb *Conium maculatum*, or spotted hemlock. The first is used to make the extract; the last, the tincture and powder. *H.* is a powerful narcotic acid poison, occasioning stupor, delirium, paralysis, convulsions, coma, and death. In small doses it is anodyne, alterative, resolvent, antispasmodic, and anaphrodisiac, and has been exhibited in cancer, dropsy, epilepsy, rheumatism, scrofula, syphilis, and other diseases. *H.*, whether in leaf or powder, rapidly deteriorates by keeping. *Imp.* duty: seed and leaf, free; extract, 40 per cent.

**Hemlock Bark**, the bark of the Hemlock Spruce, *Abies canadensis*, a tree which forms a great part of the forests of our Northern States and of Canada. Its timber is not much esteemed, as it splits very obliquely, and decays rapidly in the atmosphere; but its bark, although inferior to oak bark, is largely used in tanning. It is usually cut into lengths of 4 feet, and is sold by the cord.

An extract of *H. B.*, used for the same purpose, is extensively manufactured in the State of New York and in Canada. *Imp.* duty: bark free; extract, 20 per cent.

**Hemlock Gum**, a name sometimes incorrectly given to Canada pitch.

**Hemmer**, a sewing-machine attachment used for turning over the edge of a piece of fabric so that the flap may be stitched down.

**Hemmell**, a shed or hovel for cattle.

**Hemming**, **Himming**, a shoe or sandal made of raw hide.

**Hemp** [*Fr.* *chauvre*; *Ger.* *Hanf*; *It.* *canape*; *Russ.* *konapli*, *konopel*; *Sp.* *canamo*], a valuable plant (*Cannabis sativa*) of the nettle tribe, remarkable for the tenacity, durability, and elasticity of its fibres. It grows in Eastern countries, and from a remote period has been distributed over the N. E. of Europe. At present it is reared principally in Russia and Poland, and in Italy near Naples. The plant is graceful in form, rising in northern latitudes to the height of 5 or 6 feet, and on the fertile soils of warm countries to 12 feet. It prefers a rich vegetable soil, and possesses the anomaly of growing upon the same spot for successive years without degeneracy. The seed is

Fig. 266. — HEMP.

sown in northern countries toward the end of April or beginning of May, and the plant is pulled in autumn. Being dioecious (that is to say with male and female flowers on different plants), there are two harvests; the first, of the male plants after they have discharged their pollen; the second, of the female, or seed-bearing plants, about a month later, when the seeds are ripened. The former is distinguished from the latter by its numerous flowers. After being pulled and dried (the female plants being besides slightly thrashed in order to separate the capsules from the stems), *H.*, like flax, is subjected to a steeping or water-rotting process, in order to destroy the texture of the glutinous substance which connects the fibres to the woody part of the stem. Sometimes the steeping process is omitted, and the *H.* is simply dew-rotted, by being exposed, spread out on the ground, to the influence of rain and moisture. When the fibres have been softened, or rather the glutinous substance softened, by rotting, the stalks are taken up, dried in the open air or in the sun, and sometimes in heated rooms. All the subsequent processes are so nearly like those from flax that it

will suffice to refer to the article FLAX for an account of them, — so far, at least, as concerns the use of *H.* in making textile fabrics; such as canvas, bagging, sacking, sail-cloth, tarpaulin, tent-cloth, marquee-cloth, etc. Jute is becoming a formidable rival to *H.* and flax in various manufactures. *H.*, however, maintains its superiority for many kinds of cordage (see ROPE).

*H.* was introduced in the North American colonies soon after their settlement by the English. It is mentioned as growing in New England prior to 1532; and bounties were offered for its cultivation in Virginia as early as 1751. It was extensively raised in the U. States during the first half of this century; but the importation into this country, in yearly increasing quantities, of a variety of other vegetable substances of the same nature, and applied to the same purpose, as coir, Manila *H.*, jute, etc., has utterly discouraged the production of *H.*, and the *H.* crop, which once amounted to 30,000 tons in Missouri and Kentucky only, has fallen even there to insignificant figures. Our importation of *H.*, which was chiefly from Russia, has been also almost entirely discontinued. In the official reports for the year 1878 the importation of raw *H.* figures for 20,503 tons, valued at \$2,221,164; but in this total are included India, Manila, and like substitutes for hemp; and it is evident, for instance, that its 19,403 tons, valued at \$2,047,147, imported from Spanish possessions, consist of Manila *H.* imported from the Philippines. See COIR, JUTE, MANILLA *H.*, etc.

**Indian *H.*** Two plants are popularly so called. The Indian *H.* or *sunn*, used for cordage, is the fibre of the *Crotalaria juncea*, a totally different plant from the *Cannabis sativa*, which is never used by the Hindoos for cloth or cordage. *Sunn* is grown in various places of Hindostan. The strongest, whitest, and most durable species is produced at Comercooly. Though deficient in toughness, it is imported to some extent into this country through England. — The Indian *H.*, which is so highly prized for its narcotic virtues, is considered by some botanists as identical with, and by others as a distinct variety of, the common *H.*, *Cannabis sativa*. This herb, and the resin obtained, are largely employed in Asia, and in some parts of Africa and S. America, for the purposes of indulgence. The whole plant dried is known by the name of *gunjah* in the markets of Calcutta. The largest leaves and seed-capsules separated from the stalks are called *bang*, *subjee*, or *sidhee*. The tops and tender parts of the plants, collected just after the flowering-time, are in some places sold under the name of *hashesh*. The dried flowers, called *kief* in Morocco, contain so much of the narcotic principle that a small pipe filled with them, if smoked, will suffice to intoxicate. The dried pistils of the flower enter into the composition of the Turkish *mad-joun*. The resin which naturally exudes from the leaves and flowers, when carefully collected by hand, is known as *moneea*; the same, when beaten off with sticks, is sold under the name of *churrus*. An extract obtained by the use of butter, when mixed with spices, forms the *dawamese* of the Arabs, and is the foundation of the *hashesh* of many Eastern countries and districts. The dried plant is smoked, and sometimes chewed. Five or ten grains reduced to a powder are smoked from a common pipe along with ordinary tobacco, or from a water-pipe with a peculiar variety of tobacco called *tombeki*. The resin and resinous extract are generally swallowed in the form of pills or boluses. The hemp-plant and its preparations appear to have been used from very remote times. The effects of the natural resin, or *churrus*, have been carefully studied in India by Dr. O'Shaughnessy. He states that when taken in moderation it produces increase of appetite and great mental cheerfulness, while in excess it causes a peculiar kind of delirium and catalepsy. The effect produced by hemp in its different forms varies, like that of opium, both in kind and in degree, with the race of men who use it, and with the individual to whom it is administered. Upon Orientals its general effect is an agreeable and cheerful character, exciting them to laugh, dance, and sing, and to commit various extravagances. It, however, renders some excitable and quarrelsome, disposing them to acts of violence. In this country its action is less marked. It is largely used in medicine in the form of extract or tincture.

**Imp. duty:** raw *H.*, also India, Manila, and like substitutes for *H.*, \$25 per ton. — All unenumerated manufactures, wholly or partly of *H.* (*H.* chief value), other than such as can be measured by the sq. yard 30 per cent. See BAGGING, CARPETING, LINEN, etc. — Indian *H.*, a crude drug, free.

**Hempen**, made of hemp.

**Hemp-Seed** [Fr. *chenvis*; Ger. *Hanfseed*; It. *cannapuccia*; Russ., *kinopljanoe senja*], the seed of the hemp-plant, sold for feeding cage birds. A useful oil is obtained from it by expression, which is employed for paints, for lamps, and for making soft soap.

**Hemstitch**, a particular mode of sewing by drawing the threads of the fabric and separating them.

**Henbane**, the *Hyoscyamus niger*, a biennial herb which grows abundantly in the Southern States and in Michigan, and is cultivated in Europe for the medicinal properties of its leaves. The *H.* of commerce is chiefly imported from Manheim in balls of 175 lbs. *Imp.* free.

**Henna**, an East Indian coloring substance obtained from the shoots of the *Lawsania inermis*. The Mohammedan women use it for dyeing the nails red; the manes and tails of the horses in Arabia are also stained red in the same manner. The distilled water of the flowers is used as a perfume.

**Hen-Roost**, a perch on which poultry roost at night.

**Hepatic Aloes**, a variety of the Socotrine aloes. See ALOES.

**Heraldic Engraver**, a die-sinker; a seal-engraver.

**Herb**, a plant with a soft or succulent stalk or stem, which bears its flower and fruit once only, and then with its root wholly perishes. There are two kinds: *annuals*, which perish the same year; and *biennials*, which have their leaves the first year, and their flowers and fruit the second, and then die away. The roots, stems, and leaves of many *H.* are used for culinary purposes; others are used in medicine and sold by druggists or herbalists.

**Herbage**, pasture for cattle.

**Herbalist**, one skilled in the properties of herbs; a dealer in medicinal plants, who supplies the trade and public.

**Herbarium**, a collection of dried plants.

**Herd**, to tend cattle, or take care of a flock; the person who looks after live-stock; a troop or body of cattle.

**Herds-Grass**, a name for timothy-grass, *Phleum pratense*. See HAY.

**Herds, Hards**, the refuse of flax.

**Herdsmen**, a cattle-keeper.

**Hereditaments**, the stationary and immovable things inherited unless otherwise devised.

**Hermetically Sealed**, perfectly closed and impervious to air, as vegetables or fruits preserved in a soldered can.

**Hereford Cattle**. See CATTLE (NEAT).

**Hermitage**, a French wine, both white and red, and the most celebrated of the wines of the Rhône, grown in the department of the Drôme, near Valence. *H.* wine is styled by the French the richest colored in their great variety of wines, but it differs much with the seasons as to quality. Red *H.*, when it is of the first quality, is not bottled for exportation until it has been 4 or 5 years in the cask, in which, as well as in bottles, it is generally sold at that age. The price in the former case is high, even if the quality be moderate. In bottle the best sells for about 4 francs. The price of this wine is regulated by the quality, together with the demand for exportation, and not by the quantity or scarcity. It is fermented in large vats, but its treatment is not so perfect on the whole as that of some other French wines. The red contains 12.32 of alcohol, and the white 17.43. The white *H.* is made of white grapes only, and divided

into three growths. This is the finest white wine France produces. Its color should be straw-yellow; its odor is like that of no other known wine. It is of a rich taste, between that of the dry and luscious wines. It is often in a state of fermentation for two years, but is never delivered to the consumer, if it can be avoided, until fermentation is complete. It keeps much longer than the red, even to the extent of a century, without the least deterioration, though after 25 or 30 years old it assumes somewhat of the character of certain of the old Spanish wines, and its perfume and taste undergo a change. *Ermilage-paille*, or straw *H.*, is made from white grapes, carefully selected out of the most perfect and best. These are dried on straw for six weeks or two months, and then submitted to the press. But little is made, and that carries a very high price; for to obtain it in perfection, a season which brings the fruit to exact maturity is required, dry without cold, during the time the grapes are exposed on the straw. *Ermilage-paille* is a rich, luscious, sweet wine.

**Hernant-Seed**, a commercial name for the seeds of a large East Indian tree, the *Hernandia ovigera*, exported to England for tanning purposes.

**Herring** [Fr. *hareng*; Ger. *Häring*, *Hering*], the *Clupea harengus*, a most valuable fish, both when fresh and when salted, ranked by Cuvier in the same order with the sprat, shad, anchovy, and white bait. The body is covered with scales, the upper part is blue or green according to the light, the lower part of a silvery white; ordinary weight  $5\frac{1}{2}$  oz., and length 10 to 12 inches; owing to the gill-lids being very loose and opening wide, it dies almost the instant it is taken out of the water.

The opinion, once entertained, that the proper home of the *H.* is within the Arctic Circle, and that its vast shoals issue thence at certain seasons, migrating southward, and spreading themselves along the shores of Europe, Asia, and America, is now discarded as utterly without foundation; and the *H.* is believed to be an inhabitant of deep water, from which, at certain seasons, it approaches the shores, probably never migrating to any great distance. The young are abundant in the shallow water near the shores at seasons when the parent fish are absent. The *H.* seems always to deposit its spawn in comparatively shallow water, and is said to be very indifferent whether the spawning-ground be sandy, rocky, or covered with submarine vegetation. Certain localities, however, have the reputation of being favorite spawning-grounds. When the great annual shoals of herrings appear on the coasts, they generally swim near the surface of the water, and are followed by multitudes of larger fishes, as hakes, dog-fishes, etc., which prey on them; great numbers also fall a ready prey to gulls and other sea-birds, which congregate for the occasion. The food of the *H.* is believed to consist chiefly of minute crustaceans and *acalephæ*; but it feeds also on small fishes, not scrupling to devour even the young of its own species. The immense multitudes of herrings annually taken by the net cause no apparent diminution of their abundance, the destruction being compensated for by prodigious fecundity; more than 68,000 eggs have been counted in the roe of a single female. But *H.*, without any apparent cause, often desert parts of the coast where for a time they have been remarkably abundant, not returning in similar plenty till after the lapse of a number of years. Such seems to be the case on our Eastern coasts. Until the last 30 years it frequented the harbors of Cape Cod in myriads from

March till June; since that time it has become comparatively rare. *H.* are full of roe in the end of June, and continue in season till the beginning of winter, when they deposit their spawn. Though the produce of our fisheries is very large (see SEA FISHERIES), *H.* are yearly imported from the Dominion of Canada and Newfoundland. The imports of pickled *H.* for the year 1878 amounted to 58,082 bbls., valued at \$230,533. Imp. duty: pickled or salted, \$1 per bbl., or 50 cts. per 100 lbs.

The mode of fishing for *H.* is by drift-nets, very similar to those employed for taking mackerel and pichard, with a slight difference in the size of the mesh. The net is suspended by its upper edge from the drift rope by various shorter and smaller ropes called buoy ropes; and considerable practical skill is required in the arrangement, that the net may hang with the meshes square, smooth, and even in the water, and at the proper depth; for according to the wind, tide, situation of their food, and other causes, the *H.* swim at various distances from the surface. — The size of the boat used depends on the distance from shore at which the fishery is carried on; but whether in deep or in shallow water, the nets are only in actual use during the night. It is found that the fish strike the nets in much greater numbers when it is dark than when it is light; the darkest nights, therefore, and those in which the surface of the water is ruffled by a breeze, are considered the most favorable. It is supposed that nets stretched in the daytime alarm the fish, and cause them to quit the places where that practice is followed; it is therefore strictly forbidden. *H.* are brought to market in three forms: *fresh H.* are the condition in which they are taken from the sea; *white or pickled H.* are merely salted and put into barrels; *red H.* are gutted and salted, and afterwards hung up and fired with the smoke of green wood. *Fresh H.* are consumed in considerable quantities in towns adjoining the coast; but it is the pickled and *red H.* which form the great objects of the fishery. The *boat fishery* is that chiefly pursued when the fishing-ground is not at a great distance from the shore. The *deep-sea fishery*, where the fishermen go out to sea wherever the fish are to be found, requires vessels of a larger description (generally from 30 to 80 tons), as the *H.* are pickled and stowed on board. The vessels fitted out for this fishery commonly meet with the earliest and best *H.*; and owing to the circumstance of the fish deserting parts of the coast which they have been accustomed to frequent, it is a more regular source of profit than the boat fishery, though it requires larger capital.

At Yarmouth, which is the great seat of the English *H.* fishery, the fish are counted thus: the last of *H.* is 13,000; the barrel is 26½ and the cran 37½ Imp. gallons; a cade is 500 *H.*

**Herring-Bone**, a kind of cross-stitch in seams, mostly used on woollen work.

**Herse**, the French name for a harrow. See HEARSE.

**Herst-Pan**, a frying-pan.

**Heap**, in weaving, the length of two hanks of linen thread.

**Hesse** (*Grand Duchy of*), a central state in the W. of Germany, comprising two disconnected territories separated from each other by the Rhine, and bounded N. by the Prussian province of Hesse-Nassau, E. by Bavaria, S. by Baden, and W. by Rhenish Bavaria and Prussia. Area, 2,866 sq. m. The surface of the E. portion of both parts is mountainous. The country is fertile, and agriculture in a flourishing condition. Fruit is abundant, and the vine highly cultivated. The principal manufactures consist of damask, linens, silks, tobacco, earthenware, and chemicals. *H.* is divided into the 3 prov. of Upper *H.* (Oberhessen), Rhenish *H.* (Rhein Hessen), and Starkenburg. *Darmstadt*, the capital, is situated on the River Darm, 15 m. S. of Frankfort-on-the-Main; pop. 44,088. The chief commercial city of *H.*, and next to Cologne the principal mart for Rhenish produce in Germany, is *Mayence* or *Mentz*, an old city, situated on the Rhine, near its junction with the Main, in lat. 49° 59' 44" N., lon. 8° 16' 32" E. Pop. 57,847. The government is a constitutional monarchy, the legislative power being vested, in part, in two chambers, called the Upper and the

Lower House of Representatives. The budget is granted for the term of 3 years by the chambers. The revenue for the financial period 1879-1881

**Hewer**, a worker in wood; a stone-mason; a collier; one who cuts or shapes the rough material.

Fig. 267. — MAYENCE.

was given at \$5,476,781, and the expenditure at \$4,576,858. The public debt, incurred mainly in recent years for the construction of a network of State railroads, amounted in 1879 to 25,382,000 marks, or \$6,345,500. Pop. 884,218.

**Hessian Boots**, a kind of long boots.

**Hessians**, a coarse fabric of jute and hemp, used for bagging, and manufactured at Dundee, Scotland.

**Hew**, to cut by blows with an edged instrument; to shape with an axe.

**Hexachord**, a musical instrument with six strings.

**Hhd.**, the commercial abbreviation for hogshead.

**Hickory**, a tree (*Carya*) growing on a large scale in many parts of the U. States. Several species are recognized, though no difference can be distinguished in their timber, which is cross-grained, red at the heart, heavy, and exceedingly tough and strong; but it is subject to be attacked by worms, and it decays quickly when exposed to the weather. It is chiefly employed for carriage-shafts and springs, large screws, chair-backs, hoops, whip-handles, and similar purposes. The *H.* is distinguished from the *Juglans* or true walnut by the shell of its nuts not being deeply furrowed. The nuts of one species (*C. oliviformis*), called pecan-nuts, are much esteemed as a table-fruit, and are also exported to some extent to England.

**Hide** [Fr. *peau*; Ger. *Haut*; It. *cuoja*; Port. *pelle*; Sp. *pellejo*, *piele*], signifies, generally, the skin of a beast, but the term is more generally applied to the skins of bulls, cows, horses, buffaloes, etc., which form an important branch both of our inland and foreign trade. Various kinds are distinguished. Raw or green hides are those in the state in which they are taken from the carcass; salted hides are those dressed or seasoned with salt, alum, or saltpetre, to prevent them from putrefying; and tanned or cured hides. The buffalo hide is larger and heavier than that of the ox, and is, besides, distinguished by a tuft of hair on the shoulders. Losh hides are buffalo and others dressed in oil in the same way as chamois skins. Muscovy or Russian hides are tanned and colored of a brown or red color. In commerce, *hides* is the name for the skins of the large animals above enumerated, and *skins* for the finer pelts. The *H.* of S. America are in the highest repute, and vast quantities of them are imported. *Imp.* free.

The exports for the year 1878, chiefly to Canada, England, France, and Germany, amounted to \$1,286,840. See **FUR** and **LEATHER**.

Table of the Foreign Imports of Raw Hides and skins into the U. States for the year 1878.

Whence imported.	Value.	Whence imported.	Value.
Argentine Rep....	\$3,380,747	British Poss. Africa	\$209,727
Belgium.....	251,164	Mexico.....	1,545,546
Brazil.....	1,288,085	Dutch W. Indies..	172,681

**Hide Cuttings**, in the leather manuf., the trimmings of raw hides, which are sold for making glue.

**Hide-Rope**, rope made of strands of cowhide plaited, which is very durable, and used for wheel-ropes, traces, jigger and purchase ropes.

**Higgler**, a chafferer; a travelling dealer in provisions or small wares.

**Higgling**, chaffering; tedious in bargaining.

**High**, dear; costly; above the usual prices.

**High 'Change**, the moment of the day at which the largest number of merchants are found on 'Change.

**High Figure**, at the full value, or above the market price.

**High-pressure Engine**, a steam-engine in which the steam is not condensed, but admitted into the cylinder at a very high temperature, and therefore an exceedingly strong boiler is required.

**High-Road**, a public way for vehicles, etc. See **HIGHWAY**.

**High Seas**, the water of the ocean without the boundary of any country, and they are within the exclusive jurisdiction of the admiralty up to high-water mark, when the tide is full. The open ocean which washes the sea-coast is used in contradistinction to arms of the sea enclosed within the *fauces terreæ*, or narrow headlands or promontories; and under this head are included rivers, harbors, creeks, basins, bays, etc., where the tide ebbs and flows. They are within the admiralty and maritime jurisdiction of the U. States; but if they are within the body of a county of any particular State, the State jurisdiction attaches.

**High-seasoned**, flavored with spices or other seasoning.

**High-Water**, the highest state of the tide; the turning point just before the ebb commences. See **TIDE**.

**High-water Mark**, the mark made on the shore when the tide is at its highest.

**Highway**, a public thoroughfare, or road, for traffic. It is a settled principle in the English law, that the right of soil of owners of land bounded by the sea, or on navigable water, where the tide ebbs and flows, extends to high-water mark; and the shore below common, but not extraordinary, high-water mark belongs to the State as trustee for the public; and in England the crown, and in this country the people, have the absolute proprietary interest in the same, though it may, by grant or proscription, become private property. The public have, at common law, a right to navigate over every part of a common navigable river, and on the large lakes. The public, in cases where the river is navigable for boats and rafts, have an easement therein, or right of passage, subject to the *jus publicum*, as a public highway. Each proprietor is entitled to a larger or smaller proportion of the alluvial formation and shore line, according to the extent of his original line on the shore of the river. In the case of rivers not navigable, it belongs to the owners of the adjoining land. This principle of the common law is recognized and prevails in the States of Maine, New Hampshire, Massachusetts, Connecticut, New York, New Jersey, Maryland, Ohio, Virginia, North Carolina, Louisiana, etc.

**High Wines**, a proof kind of spirit in distillation, contradistinguished from low wines.

**Hilt**, the upper part of a sword or other weapon or tool.

**Himt**, an old German corn measure, varying in different localities. It ranges from 5½ up to

nearly 10 gallons. In Hanover 96 himtens are equal to 82 bushels.

**Hina**, the name for a gourd or melon in the Pacific islands.

**Hind**, the female of the red deer, of which the male is the stag. — A farm servant; a peasant.

**Hing**, the East Indian name for asafetida; hingra being the coarsest kind of the drug.

**Hinges**, movable metal ligaments, or connected plates, for the joints of doors, gates, etc., to turn on. See **BUTTS**.

**Hink**, a reaping-hook.

**Hip-Knobs**, ornaments at the gable end of houses.

**Hippocras**, an aromatic cordial or spiced wine, formerly in high repute in England.

**Hippodrome**, a circus for feats of horsemanship.

**Hippopotamus-Hides**. The tanned skin of this pachyderm is used by mechanical engineers, and also formed into shields and other articles.

**Hip-Strap**, a strap which, crossing the buttocks of a horse, supports the breeching or the traces merely, according to the style of harness.

**Hire**, wages or compensation for services.

**Hirling**, a small sea-trout like a salmon, with reddish flesh.

**Hirsell**, a flock of sheep; the act of classing or sorting into breeds or flocks.

**Hirst-Frame**, in forging, the frame of a tilt-hammer.

**Hissa**, an Indian term for a share or division.

**Histrionic**, a dramatic performer.

**Hitch**, a knot or noose in a rope for fastening it to anything, of which there are many kinds: as a half-hitch, clove-hitch, Blackwall-hitch, magnus-hitch, timber-hitch, etc. — A slip (see Fig. 85, in article **COAL**).

**Hive**, a box or rush basket for a swarm of bees to lodge and work in; commonly called bee-hive.

**H. M. C.**, **H. M. S.**, abbreviations for "her Majesty's customs — her Majesty's ship — her Majesty's service."

**Ho**, a Chinese measure of capacity, about 7½ gallons.

**Hoarding**, a boarded enclosure or fence, fixed about any building which is being erected or repaired. — The act of accumulating or saving.

**Hoastman**, a coal-fitter, one who vends coals at a seaport.

**Hob**, the flat iron projection at the side of a fire-grate. — The nave of a wheel. — A boor.

**Hobart-Town**. See **TASMANIA**.

**Hob-Nail**, a clout-nail; a short nail with a large head, used for nailing strong country boots.

**Hock** is a name loosely applied in England to all German wines, either still or sparkling, from Hockheim, the place near which is grown the celebrated Hockheimer wine.

**Hockheimer**. See **GERMANY (WINES OF)**.

**Hod**, a bricklayer's or plasterer's box or tray, fixed at the end of a staff, in which to carry bricks and mortar on the shoulder.

**Hodden Gray**, cloth made of wool in its natural state, without being dyed.

**Hodge-Podge**, an Irish stew; a mixture of vegetables and meat.

**Hodman**, the bearer of a hod; one who carries mortar or bricks in a hod to other workmen on a building.

**Hoe**, an agricultural instrument of iron, for farm or garden use, employed to turn up weeds, and loosen the soil round plants. The hand-*H.* is a thin plate of iron 6 to 8 inches broad, and sharpened on the edge fixed at right angles on the extremity

of a pole or rod, which serves as a handle. This is called a *draw-H*, because in the operation of hoeing the instrument is drawn or pulled toward the operator. Another kind of garden *H* has the blade or iron plate fixed on the extremity of the handle, and in continuation of it; and this is called a *thrust-H*, because in hoeing the operator always pushes the *H* forward. This kind is also called the *Dutch H*, most probably from having been first introduced from Holland. In agriculture, *H*, of the thrust kind are drawn by beasts of burden,

Fig. 268. — BUCKNALL'S HORSE-HOE.

and commonly called *horse-H*, or *hoeing-machines*. In general form they resemble a plough; but instead of the share they have one or more iron blades or plates with sharp edges, fixed to perpendicular iron rods at their lower extremities. These sharpened plates, being drawn through the soil, cut through the roots of weeds an inch or two beneath the surface. Agricultural or field *H*, are only used in the case of those field crops which are sown or planted in rows. There are a great many kinds of field or horse *H*, chiefly differing in the number of blades which are attached to the common frame for stirring and cleaning a greater or smaller number of spaces between the rows of drilled crops at once. Fig. 268 represents the English Bucknall's horse-*H*, which is used for hoeing wheat.

**Hoe, Hoigs** [Scotch], stockings; hose.

**Hoffman**, a fire-insurance Co., located in New York City, and organized in 1864. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$200,000; net surplus, \$78,847.09; risks in force (fire), \$13,426,881; premiums (fire), \$134,539.81; inland, \$2,500; premiums, \$125; premiums received since the organization of the Co., \$1,962,635.29; losses paid, \$1,249,395.54; cash dividends paid to stockholders, \$130,000.

**Hog**, a well-known animal of the swine family, whose flesh, called *pork*, constitutes one of the most important articles of our national commerce, both domestic and foreign.

Of all quadrupeds the *H* is the most gross in his manners, and therefore has been regarded as the very personification of impurity. The Jews were strictly enjoined not to eat its flesh; and the Mohammedans agree in this respect with the Moslem prohibition. In most parts of Europe and America, however, it constitutes a very material part of the food of mankind. The *H* is an animal of a remarkably prolific nature; and as they bring forth from 10 to 15, and sometimes 20, at a litter, they would soon become very numerous, were they not diminished for the support of man. Their flesh, says Linnaeus, is wholesome food for persons of athletic constitutions, — those who habituate themselves to much exercise, — but improper for such as lead sedentary lives. It is, however, an article of general consumption, and one which is of great importance to a naval and commercial nation, as it takes salt better than any other flesh, and consequently is capable of being longer and more easily preserved than any other. The Jews and the Mohammedans not only abstain from the flesh of swine from a religious principle, but even consider themselves defiled by touching it. The Chinese, on the contrary, are so excessively fond of pork that many, owing to this partiality alone, as it is

said, have been prevented from conversion to Mohammedanism. The fat of swine differs, in its situation, from that of almost every other quadruped, as it forms a thick, distinct, and continued layer betwixt the flesh and the skin. *Lard*, which is chiefly obtained from the fat membranes of the abdomen, is applicable to various uses, both culinary and medicinal; and when good is white and moderately hard. The skin, when properly dressed, is used for the seats of saddles; it is also employed by various artificers. Great attention has been paid in this country to the improvement of the various breeds; and by judicious crosses much has been effected both as to quality and size. Swine were probably introduced from Spain into Hispaniola by Columbus in 1493, into Florida by De Soto into 1538, into Canada in 1608, and into Virginia in 1609, where they multiplied so rapidly that in 18 years the people were obliged to padisade Jamestown to keep them out. Different breeds are prized in different districts, according to the fancy of producers, the facility of raising them, and the particular object of the farmer. The Chinese *H* (Fig. 269), both the white and black varieties, are easily fattened, and have small bones; indeed, they are generally too fat to be esteemed as pork, and are considered to make poor bacon. Bred carefully, and mixed with other stock, they are valuable animals. The Neapolitan is the most celebrated from the improved varieties of ancient Rome, and the stock of most of the English breeds. Though not very hardy, the flesh is of superior quality. It is small, black, with few bristles, short snout, erect ears, and small bones. Crossed with the Berkshire breed, the form is improved and the constitution hardened, with a remarkable tendency to fatten easily. The Berkshire (Fig. 270), an English breed, black or white,

is larger than the Neapolitan, with more bristles, and less fat to the meat, which is well suited for bacon and hams. This was formerly preferred above all others in many parts of New England; but its cross with the Chinese is more profitable, as the weight is heavier with light feeding, and the disposition milder. The Essex, crossed with the Neapolitan, is one of the most valuable, and has taken more prizes in England than any other breed. It is black, of good size and symmetry, mild disposition, easily fattened, the meat of excellent quality, and the dressed weight at 12 and 18 months 250 to 400 lbs. It is not subject to cutaneous diseases. The Irish grazer is slow in coming to maturity; but crossed with the Berkshire is an excellent variety. The Woburn or Bedford breed was originally sent by the Duke of Bedford to General Washington, and was produced at Woburn, England, by a cross of the Chinese boar and a large English *H*. When pure they are white, with dark ash-colored spots. They are of large size, with deep, round bodies, short legs, and thin hair, easily kept, and maturing early. The Middlesex is a popular breed in England, and has

Fig. 269. — CHINESE HOG.

been considerably imported into the U. S. It is derived from a mixture of the Chinese with some larger stock. The color is usually white, and the size larger than the Suffolk, weighing at 18 months 800 to 900 lbs. The bones are smaller than in the Essex. But the favorite of all breeds seems now to be the Suffolk, so named from that county in England, whence the London market has long been supplied. The present breed is believed to have originated from the old Suffolk crossed with the Chinese and Berkshire. The pure breed is remarkably symmetrical, small and compact, short-legged, and small-headed, the exact opposite of the long, lank, and lean *H*, of the western prairies. Their early maturity, small consumption of food, and tendency to fat, compensate for their want of size. The color is white. These are the most esteemed varieties. There are many others, imported and domestic, which

thrive well in peculiar districts, and which are more or less extolled by their respective fanciers. While *H.* are kept in New England and the Middle States mostly in pens, in the West they are allowed to range in the woods and fields till within 3 months of the time of killing them, feeding upon clover, corn, acorns, and mast. The number of *H.* in the U. States in 1878 was as follows:—

STATES.	HOGS.		
	Number.	Average price.	Value.
Maine.....	62,200	\$7.74	\$481,428

Total.....	32,262,500	\$4.98	\$160,838,532

Our exports of living *H.* for the year 1878, chiefly to Canada and England, amounted to 29,281, valued at \$267,259.

The *H.* is fed for two purposes. The one is to yield pork, which may be used either fresh, salted, or pickled, and for which the pigs are ready in 6 or 8 months; the other is to produce bacon, prepared by salting and drying the flesh, and for which they are ready in 10 or 12 months. The smaller class of early feeding pigs is preferred for the former purpose,

Fig. 270. — IMPROVED BERKSHIRE HOG.

the larger class for the latter. In the case of pickling pork, the carcass is cut into pieces, and packed in kits, barrels, or cases. When designed for bacon, the body is cut so as to separate the hams or legs from the flitches, or sides. The pork-packing business is carried on to a great extent and with admirable system at Cincinnati and other Western cities, and on a scale of almost incredible magnitude at Chicago, where about 30,000 *H.* per day are slaughtered, converted into hams, bacon, and pork, and packed or pickled, ready for exportation, during the winter months. See CHICAGO (Pork-Packing).

The following table exhibits, by States, for the seasons of 1877-78 and 1876-77, respectively, the number of *H.* packed between November 1st and March 1st, the average net weight, total product of lard, the average prices paid per hundred pounds net, the aggregate cost, together with the grand aggregates and general averages of the West, in a period of eight years. The table is taken from the Report of the Chamber of Commerce of Cincinnati issued in 1879.

**Hog-Fleece**, the clip of wool from a sheep that has not been previously shorn.

**Hog**, a young sheep that has not been shorn: hence the terms ewe-hog, wedder-hog, and tup-hog.

**Hogged**, a term applied to a ship, which, through some defect or strain, droops at each end.

**Hogger-Pump**, the top pump in the sinking-pit of a mine.

**Hoggers**, stockings without feet, worn by coal-miners when at work.

**Hogget**, abbreviated into hog, or tup-hog; a weaned male sheep; if castrated, he is called a wether-hog.

**Hog-Pen**, a pigsty or enclosure for swine.

**Hogshead**, a measure of capacity for wine and other measures, containing 63 gallons, or two barrels. Also a large cask used for transporting

various articles, as sugar, molasses, tobacco, etc., ranging from 750 to 1,800 lbs. in weight.

**Hog-skin-Gloves**, heavy gloves made from the tanned skin of a variety of hog from South America.

**Hog-skin-Saddle**, a superior kind of saddle made in Scotland from the tanned skin of the common hog.

**Hoist**, to lift up.

**Hoisting-Machine**, any machine or contrivance for hoisting merchandise or passengers; a block; a capstan; a crane; a derrick; an elevator; a pulley; a windlass; etc.

**Hoistway**, a square opening in the floors of ware-rooms for the convenient raising or lowering of merchandise, perpendicularly, from the lower to the upper or from the upper to the lower stories. *T. McElrath.*

**Hoja-de-Lata** [Sp.], tinned iron, — *heja-de-laton* being sheet brass.

**Hold**, the whole interior of a vessel below the decks; the space where the cargo is stowed.

**Holdfasts**, flat-headed nails. — Stout, bent pieces of iron; catches or clamps for driving into walls, etc., as supports for attached pieces.

**Hold-Water**, staying the progress of a boat by keeping the oars submerged.

**Holidays** are understood to be those days, exclusive of Sundays, on which no regular public business is transacted at particular public offices. They are either fixed or variable. Banks and public offices are only closed on fixed holidays. In England the holidays observed generally are, Good Friday, Queen's Birthday, Coronation Day (June 28), Prince of Wales's Birthday (November 9), Christmas. In the United States the holidays are, Fourth of July, Thanksgiving Day (November), Christmas. At New York and some other cities New Year's Day is also observed, and at New Orleans, January 8th.

**Holing**, undermining coal-beds. — Dibbling in plants. — Digging trenches to plant pieces of sugarcane.

**Holland, or Kingdom of the Netherlands**, a maritime kingdom of Central Europe, situated between lat. 50° 46' and 53° 34' N., and lon. 3° 27' and 7° 14' E., and bounded W. and N. by the German Ocean or North Sea, S. by Belgium, and E. by Germany, from which it is not separated by any natural barriers. *H.* comprises the territory of the ancient republic of the Seven United Provinces, with some portions of Limburg. The government is a constitutional monarchy. The present constitution, solemnly proclaimed Nov. 3, 1848, vests the whole legislative authority in a parliament composed of two chambers, called the States-General. The Upper House, or first chamber, consists of 39 members, elected by the provincial states from among the most highly assessed inhabitants of the various counties. The second chamber of the States-General, elected by ballot, at the rate of one deputy to every 45,000 souls, numbered 86 members in 1878. All citizens, natives of the Netherlands, not deprived of civil rights, and paying assessed taxes to the amount of not less than 20 guilders, or \$8.25, are voters. Clergymen, judges of the Hooze Raad, or High Court of Justice, and governors of provinces are debarred from being elected. Every two years one half of the members of the Second Chamber, and every 3 years one third of the members of the Upper House, retire by rotation. The sovereign has the right to dissolve either of the chambers separately, or both together, at any time, but new elections must take place within 40 days. The Second Chamber alone has the initiative of new laws, together with the government, and the functions of the Upper House are restricted to either approving or rejecting them, without the right of inserting amendments. The king has full veto power, but it is seldom, if ever, brought into practice. Alterations in the constitution can only be made by the vote of two thirds of the members of both Houses, followed by a general election, and a second confirmation, by a two-thirds vote, of the new States-General. The executive authority is, under the sovereign, exercised by a responsible council of 8 ministers. The Hague [Dutch, *Gra-venhuag*; Fr. *La Haye*], a fine city at 13 m. N. W. of Rotterdam, is the residence of the court and seat of government. *H.* is divided into 11 provinces, the area and population of which were as follows on Jan. 1, 1880: —

Provinces.	Area in sq. m.	Population.
North Brabant.....	3,205	457,709
Guelderland.....	3,154	453,624
South Holland.....	1,869	763,636
North Holland.....	1,706	642,073
Zealand.....	1,101	187,046
Utrecht.....	855	186,164
Friesland.....	2,047	317,405
Overijssel.....	2,076	267,826
Groningen.....	1,432	242,065
Drenthe.....	1,689	113,773
Limburg.....	1,353	235,135
Total.....	20,527	3,865,456

Connected with the kingdom, though possessed of a separate administration, is that portion of *Luxemburg* that the king of *H.* possesses with the title of Grand Duke (the other portion belonging to Belgium). The Grand Duchy of *Luxemburg* has an area of 1,592 sq. m., and a population of 197,528, so that there are 124 inhabitants per sq. m., while in *H.* the density of pop. is 179 per sq. m. By the treaty of London, of May 11, 1867, this Grand Duchy was declared a neutral country, under the protection of the Great European Powers, in case of war.

*H.* possesses a comparatively larger town population than any other country in Europe. There are 18 towns in the kingdom with a pop. of above 20,000 inhabitants, namely: —

Amsterdam.....	296,200	Leeuwarden.....	27,085
Rotterdam.....	136,230	Dordrecht.....	26,576
The Hague.....	104,095	Tilburg.....	26,103
Utrecht.....	66,106	's Hertogenbosch.....	24,583
Leyden.....	41,298	Delft.....	24,511
Groningen.....	40,589	Nymegen.....	23,509

Haarlem.....	34,797	Schiedam.....	21,880
Maestricht.....	29,083	Zwolle.....	21,563

By a law passed Sep. 17, 1870, capital punishment was abolished in *H.*, and since that period there has been a decrease of crime.

This country is composed of the lowest part of the great plain of Northern Europe, its level being indeed in many places below that of the sea, against which it is protected, partly, as in Zealand, Friesland, and Guelderland, by numerous dikes, and partly, as between the Helder and the Hook of Holland, by sandhills or *dunes* cast up by the ocean upon the shores; though, despite every precaution, it has often greatly suffered from inundations. The whole, saving some slight elevations in Guelderland, Utrecht, and Overijssel, forms one unbroken flat, without a hill or rock, without forests, or, except in the S. part, running waters; the land consisting mainly of moor and marsh, traversed, like network, by numerous canals, which, while they are absolutely necessary to drain it, and render it fit for cultivation, answer, for the most part, the purpose of roads, many of them, indeed, being navigable for large vessels. The astonishing ingenuity, industry, and perseverance by which *H.* is thus protected against inundation, and rendered at once available for cultivation and internal communication, has been amply rewarded, for the country is exceedingly fertile, and is, for its size, one of the richest, most populous, and most powerful in the world. In the northern provinces the principal natural feature is the Zuyder Zee, a shallow inland sea, separating the prov. of North *H.* from Friesland and Overijssel. There are also numerous lakes, the chief being the Haarlem-meer, a wide expanse in the vicinity of that city and Amsterdam. In the southern prov. the leading feature is the Rhine (Waal), and its tributary, the Meuse, which enter the sea by various channels, though chiefly by way of Dort and Rotterdam. Several parts of the kingdom are likewise distinguished by extensive marshes, as the Bourtaug on the N. E. frontier, and the Peel in North Brabant. As means of communication between Amsterdam and the North Sea, the Zuyder Zee has long been unsatisfactory, on account of the Pampus Bank and numerous shallows. Sometimes, in consequence of long-continued northerly and easterly winds, its bed is almost dry, and vessels are everywhere lying on the sands. A substitute was accordingly provided for it in the great North Holland Canal, one of the most stupendous works of the kind in existence. It was begun in 1819, and finished in 1825, at a cost of about \$5,000,000. It is about 50 m. in

length. Its breadth, at the surface, is 124½ ft., at the bottom 36. The depth is 20 ft. 9 in. Its level is that of the high tides of the sea, from which it receives its supply of water. This canal having been found insufficient for large steamers, it was resolved to make a more direct communication between Amsterdam and the North Sea at Why an Zee, by draining a portion of the river Y, and cutting a canal through the sand-hills. This was begun in 1845 by the Amsterdam Canal Co., and is at present (1889) in process of completion. The general aspect of *H.* is different from that of any other country in Europe. The roads and canals are usually lined with willows and other trees, which afford an agreeable shade and relieve the uniformity of the landscape. Innumerable villas are seen decorated with the utmost nicety of art. Spires, church-towers, villages, admirable for neatness and cleanliness, large and well-built cities, rapidly succeeding one another; meadows in vernal green varied by sheets of water, cattle in large herds, barges towed by horses or spreading a sail to catch a favoring breeze, — everything and every place in the highest order and perfection. — such are the sights which *H.* supplies in abundance, and in respect of which it has no parallel in any other part of the world.

**Climate.** In respect of climate, *H.* labors under many disadvantages. In winter it is much colder than England, and the waters are frequently frozen for three months. Even the Zuyder Zee is sometimes frozen over. The temperature has been sometimes as low as 23° below zero of F., and sometimes as high as 102°. In summer, cold nights often succeed to days of intense heat. The climate generally is variable. The atmosphere, especially in the western prov., is loaded with moisture, and there agues, dropsies, pleuritis, and rheumatism are frequent. Guelderland is the healthiest prov., but all the eastern side of the country is comparatively salubrious. *H.* is frequently subject to violent gales of wind, which, when they blow from the W. or N. W., are apt to cause inundations of the sea.

**Agriculture.** This remarkable country largely rewards the skill and labor of the agriculturist. The south and central prov. are the most fertile. The farms in the best parts of Zealand vary in extent from 166 to 330 acres each. In South *H.* the proportion of pasture to arable land is about 2 to 1. In Friesland the quantity of pasture is more than 8 times that of arable land. In Guelderland there are large plantations of apple, pear, and cherry trees. Tulips and hyacinths are extensively cultivated in the neighborhood of Haarlem in fields of several acres each. Pulse and garden vegetables are everywhere raised in great abundance, also wood and madder. Flax is largely cultivated in the S., and especially in the neighborhood of Dort. Utrecht and Guelderland produce considerable quantities of tobacco. The rearing of live-stock, however, and dairy husbandry, are much more important sources of national wealth than tillage. The lean cattle brought from Denmark and Germany fatten with great rapidity in the Dutch polders. Large herds of beautiful cows yield great abundance of the richest milk. Butter and cheese of the best quality are largely exported, and bring great wealth to the peasantry. The Dutch horses are good, and well adapted for draught; the best are those of Friesland. The breeds of sheep, however, are not particularly good. In North and South *H.*, Groningen, and Utrecht there are made 140,000,000 lbs. of cheese annually, the home consumption of which does not exceed one twentieth. This large quantity at its average price produces \$9,000,000 annually. The value of the butter is about \$10,000,000 more, of which their own consumption amounts to one tenth.

In 1879 the acreage of productive lands was as follows: wheat, 214,837; rye, 487,803; barley, 112,512; oats, 257,410; buckwheat, 163,829; pease, beans, etc., 131,303; potatoes, 829,917; hemp, 2,765; flax, 54,053; colza, 42,676; poppy, etc., 7,785; sugar beet, 36,152; hops, 521; tobacco, 3,904; madder, chicory, etc., 12,788. In the same year there were in farm-animals: horses, 253,393; cattle (including cows), 1,469,937; sheep, 898,715; hogs, 611,004; goats, 146,169.

The fisheries, once a principal source of wealth, have greatly declined.

**Commerce and Manufactures.** The principal manuf. are those of woollens in Leyden and Utrecht; silks in Utrecht, Haarlem, and Amsterdam; tobacco pipes at Gouda; and paper, tobacco, leather, sugar-refining, painters' colors, and cordage in various places. The distilling of geneva (see HOLLAND) is prosecuted extensively at Schiedam, and ship-building at Rotterdam and Amsterdam. Commerce, however, has always been pre-eminently the national pursuit of the Dutch. The greatness of the trade of *H.* during the 17th century, and its decline in the 18th, belong to history. For a lengthened period the Dutch engrossed nearly the whole sea-fishery of Europe, and they were long the carriers and factors of the principal European States. *H.* was still, at her emancipation from the French yoke, in 1814, the richest country in Europe. Its trade has since revived in a very remarkable manner, and has benefited greatly from the improved administration of its important colonies; so that its commercial prosperity nearly equals now that which the Netherlands obtained in its palmiest days, when Beaves said of it, in his *Lex Mercatoria*: "It produces hardly anything, and yet has wherewith to furnish

other people all they can have need of. It is without forests, and almost without wood. There are no mines or metals, and yet there is found as much gold or silver as in New Spain or Peru, as much iron as in France, as much tin as in England, and as much copper as in Sweden. The wheat and other grains that are there sowed hardly suffice for nourishment to a part of the inhabitants; and it is, notwithstanding, from hence that the greatest part of its neighbors receive them, either for their subsistence or trade. In fine, it seems as if the spices grew there, that the oils were gathered there, that it nourished the precious insects which spin the silk, and that all sorts of drugs, for medicine or dyeing, were in the number of its products and of its growth. Its warehouses are so full, and its merchants seem to carry so much to strangers, or that strangers come to load in its ports, that there is not a day, and it may be said a moment, that ships do not come in or go out, and frequently entire fleets." Such was the picture drawn of *H.* in 1670. Its present commercial condition, though different in every other respect from the Netherlands of that period, is quite as prosperous, and rests upon a basis more solid and secure.

The foreign commerce of *H.*, classified like that of Belgium and France, into "general and special," is chiefly carried on with two countries, Germany and Great Britain, the former standing first in the list as export, and the latter first as import market. No returns are kept of the value of the general commerce, but only of the weight of the goods. For the year 1878, the value of exports of home produce was 578,876, 590 gulden (\$228,676,871); and the value of imports for home consumption was 791,684,422 gulden (\$304,708,502). The imports principally consist of corn, sugar, coffee, spices, tobacco, cotton, tea, indigo, cochineal, wine and brandy, wool, grain of all sorts, timber, pitch and tar, hemp and flax, iron, hides, linen, cotton and woollen stuffs, hardware, rock salt, tin plates, coal, dried fish, bacon and hams, lard, mineral oil, etc. The exports consist partly of the produce of *H.*, partly and principally of the produce of her possessions in the East and West Indies and other tropical countries, and partly of commodities brought to Amsterdam, as to a convenient entrepôt from different parts of Europe. Of the first class are cheese and butter, madder, clover, rape, hemp, and linseeds, rape and linseed oils, Dutch linen, etc. Geneva is principally exported from Schiedam and Rotterdam; oak bark and cattle principally from the latter. Of the second class are spices, coffee, and sugar, principally from Java, but partly also from Surinam, Brazil, and Cuba; indigo, cochineal, cotton, tea, tobacco, and all sorts of Eastern and colonial products. And of the third class, all kinds of grain, linens from Germany, timber and all sorts of Baltic produce: Spanish, German, and English wools; French, Rhenish, and Hungarian wines, brandy, etc.

Table exhibiting the Value of the Commerce of Holland with the U. States for the 20 years, from 1859 to 1878.

Year.	Imports from the U. States.		Exports to the U. States.	Total Imports and Exports.
	Domestic.	Foreign.		
	\$	\$	\$	\$
1859.....	4,497,241	269,742	4,397,232	9,104,215

1877.....	10,411,757	156,578	2,547,119	13,115,454
1878.....	13,174,079	125,968	2,774,334	16,074,381
Total.....	135,038,752	3,647,908	45,233,271	183,885,921

The value of the principal articles imported from and exported to the U. States during the year 1878 was as follows: Imports: Agricultural implements, \$20,579; bread-stuffs (chiefly wheat and rye), \$3,115,880; carriages, \$11,612; cotton, raw (58,703 bales), \$3,022,189; cotton goods, \$19,216; drugs, etc., \$30,088; fruits (dried apples), \$52,003; (preserved in cans) \$1,721; iron (machinery, etc.), \$59,069; leather (and manuf. of), \$180,322; naval stores, \$193,312; mineral oil, \$2,189,848; lard oil, \$17,591; bacon and hams, \$409,596; salted beef, \$56,056; lard, \$612,674; preserved meat, \$41,053;

seeds, \$118,311; spirits of turpentine, \$69,780; starch, \$138,927; tallow, \$736,681; tobacco (leaf), \$1,864,803, (manuf. of) \$112,496; wood (timber), \$258,471; wooden ware, etc., \$19,541 — *Exports*: Argols, \$36,349; chemicals, dyes, etc., \$448,899; coffee, \$32,712; gums, \$15,075; hides and skins, \$54,905; madder, \$31,016; rags, \$11,690; seeds, \$32,674; books, etc., \$12,133; chemicals, drugs, etc., \$95,314; cotton goods, \$29,226; fancy goods, \$31,050; pickled herring, \$137,087; flax (raw), \$18,272; fruits and nuts, \$82,632; iron (pig), \$106,035; steel ingots, \$10,693; paints, \$87,035; provisions, \$52,526; silk goods, \$390,046; spices, \$73,315; spirits and cordials, \$145,377; wines, \$216,598; wood (cabinet ware), \$31,191; wool (cloth), \$44,359, (dress goods) \$31,512.

The above statement does not include the commerce of the U. States with the Dutch East and West Indies, which is given separately under the names of each of these colonies.

*Shipping.* The following table shows the number and tonnage of the vessels belonging to the mercantile navy in 1878:—

Description of Vessels.	Number.	Tons.
Ships (Fregatten) .....	179	152,497
Barks (Barken) .....	206	119,509
Brigs (Brikken) .....	79	22,997
Schooner-brigs (Schoener-Brikken) .....	170	27,010
Schooners (Schoeners) .....	310	50,915
Gallots (Galjotten) .....	203	23,265
Koff boats (Koffen) .....	275	32,272
Flofs (Fjalken) .....	221	14,044
Smacks (Smakken) .....	8	627
All other vessels (andere Zeilschepen) .....	158	6,561
Steamboats (Stoomschepen) .....	86	76,827
Total .....	1,835	526,527

During the year 1878, 196 Dutch sailing vessels and 29 steamers (aggregate tonnage, 229,592) entered, and 296 sailing vessels and 34 steamers (aggregate tonnage, 293,313) cleared, the ports of the U. States. For the same year 18 American sailing vessels (tonnage, 13,546) entered, and 22 sailing vessels (tonnage, 12,690) cleared, the ports of the kingdom of *H.*

*Finances.* The national revenue, derived mainly from excise duties, chief among them those on spirits, from direct taxes on land and assessed, and from stamps, amounted for the year 1878 to 142,474,363 guilders, or \$54,852,629; and the expenditures, from which the interest upon the public debt forms the principal branch, to 118,199,296 guilders, or \$45,506,928. These figures do not include the revenue and expenditure of the East India possessions, which are given under JAVA. The following table gives the division of the national debt of the kingdom of *H.*, with the annual interest:—

Funded Debt.	Nominal Capital.	Annual Interest.
	Guilders.	Guilders
2½ per cent debt .....	632,099,402	15,802,485
8 per cent .....	91,822,950	2,739,688
3½ per cent redeemable debt .....		
April 1, 11,400,000 guilders }	11,250,000	391,125
October 1, 11,100,000 " }	219,899,500	8,795,980
4 per cent debt .....		
Total .....	964,571,852	27,729,278
	\$367,510,163	\$10,696,772

*Banking, Credit, Discount, etc.* The celebrated Bank of Amsterdam was founded in 1609, on strictly commercial principles and views, and not to afford any assistance, or to interfere with the finances of the state. Amsterdam was then the great entrepôt of the commerce of the world, and of course the coins of all Europe passed current in it. Many of them, however, were so worn and defaced as to reduce their general average value to about 9 per cent less than their mint value; and, in consequence, the new coins were immediately melted down and exported. The currency of the city was thus exposed to great fluctuations; and it was chiefly to remedy this inconvenience and to fix the value or par of the current money of the country, that the merchants of Amsterdam established a "bank," on the model of that of Venice. Its first capital was formed of Spanish ducats or ducatoons, a silver coin which Spain had struck in the war with Holland, and with which the tide of commerce had enriched the country it was formed to overthrow. The bank afterwards accepted the coins of all countries, worn or new, at their intrinsic value, and made its own bank-money payable in standard coin of the country, of full weight, deducting a "brassage" for the expense of coinage, and giving a credit on its books, or "bank-money," for the deposits. The Bank of Amsterdam professed not to lend

out any part of the specie intrusted to its keeping, but to retain in its coffers all that was inscribed on its books. In 1672, when Louis XIV. penetrated to Utrecht, almost every one who had an account with the bank demanded his deposit, and these were paid off so readily that no suspicion could exist as to the fidelity of the administration. Many of the coins then brought forth bore marks of the confiscation which happened at the Hôtel de Ville soon after the establishment of the bank. This good faith was maintained till about the middle of the last century, when the managers secretly lent part of their bullion to the East India Company and Government. The usual "oaths of office" were taken by a religious magistracy, or rather by the magistracy of a religious community, that all was safe; and the good people of *H.* believed, as an article of their creed, that every florin which circulated as bank-money had its metallic constituent in the treasury of the bank, sealed up and secured by oaths, honesty, and good policy. This blind confidence was dissipated in December, 1790, by a declaration that the bank would retain 10 per cent of all deposits, and would return none of a less amount than 2,500 florins. Even this was submitted to and forgiven. But four years afterwards, on the invasion of the French, the bank was obliged to declare that it had advanced to the states of *H.* and West Friesland, and the East India Company, more than 10,500,000 florins, which sum it was, of course, unable to make up to the depositors, to whom, however, it assigned its claims on the states and the company. Bank-money, which previously bore an agio of 5 per cent, immediately fell to 16 per cent below current money. This epoch marked the fall of an institution which had long enjoyed an unlimited credit and had rendered the greatest services.

The actual *Bank of H.* was founded at Amsterdam in 1814. It is not, like the old Bank of Amsterdam, merely a bank of deposit, but a bank of deposit and circulation, formed on the model of the Bank of England. Its capital, which originally amounted to 5,000,000 florins, was doubled in 1819. It has the exclusive privilege of issuing notes. Its charter was prolonged in 1863 for a period of 25 years.

The credit allowed at Dutch ports on most articles is 3 months; some articles, however, are always sold for ready money; a discount is generally given in prompt payments; but the terms of credit on most articles and the discount allowed for ready money have been fixed by usage, and are regarded as essential conditions in every bargain. Some of the more important of these terms and discounts are specified in the following table. In consequence of the preference given in *H.* to ready-money transactions, it is not a country in which adventurers without capital have much chance of speedily making a fortune; and it should be mentioned to the honor of the Dutch, and as a proof of the excellence of their ready-money system, that, notwithstanding the distress and loss of trade occasioned by the invasion and occupation of their country by the French, the bankruptcies in 1795 and subsequent years were not, comparatively, so numerous as in England in ordinary seasons. The regulations in the Code Napoléon as to bankruptcy are enforced in *H.*

It has long been the practice in *H.* to make, on selling articles, considerable deductions from their weight, particularly from those of large bulk, as compared with their value. These tares and drafts, as they are termed, are now fixed by ancient usage, and the most important amongst them are here specified.

*Tares and Allowances on the Principal Articles sold at Amsterdam.*

Articles.	Tares and Allowances	Discount
Coffee .....	3 per cent .....	cash 1 per cent; Neth Trading Co., 1½ per cent.
Rice: in bales .....	3 kilos. per bale, 1½ per cent, and 2 per cent.	2 per cent and 1 per cent for cash.
casks .....	2½ kilos. per cask, and 13 per cent.	ditto.
half-casks .....	2½ kilos. per ½ cask, and 14 per cent.	ditto
Tobacco: Maryland .....	net weight, 1 per cent, 2 per cent, 3 per cent, and 8 per cent.	1 per cent and 1 per cent for cash.
Virginia .....	3 per cent .....	ditto.
Kentucky .....	ditto .....	ditto.
Java .....	2 kilos. per bale .....	1 per cent for cash.
other kinds .....	according to agreement.	
Butter: Friesland .....	7 kilos. per firkin ..	none.
N & S. Holland .....	8 kilos. per firkin, and 4½ kilos. per half-firkin.	none.
Cheese: Gouda and Leyden .....	1 per cent .....	1 per cent for cash.
Edam .....	2 per cent .....	ditto.
Cocoa .....	3 per cent .....	ditto.

## Tares and Allowances. — Continued.

Articles.	Tares and Allowances.	Discount.
Indigo .....	1 per cent and 2 per cent	1 per cent for cash.
Cochineal.....	real tare .....	2 per cent and 1½ per cent for cash
Fustic.....	12 kilos per mille, 2 per cent and 3 per cent	2 per cent and 1 per cent for cash.
Logwood .....	ditto .....	ditto
Gums.....	real tare, 1 per cent and 2 per cent	ditto.
Madder .....	real tare, and 5 kilos per cask. Casks are charged in account at about 5s. each.	ditto.
Raw sugar: casks ..	15 per cent .....	1½ per cent for cash.
cases .....	18 per cent .....	ditto
mats .....	8 per cent .....	ditto.
bags .....	ditto .....	ditto.
baskets .....	1 per cent and 12 per cent.	1 per cent and 1½ per cent for cash.
Molasses .....	1 per cent, 2 per cent, and 13 per cent.	2 per cent and 1 per cent for cash
Tin plates.....	—	1 per cent for cash
Herrings.....	—	ditto
Cotton: Surat, Bengal, American, and Surinam .....	6 per cent. ....	ditto.
Japan and Chinese .....	net weight.....	ditto.
Gin .....	—	cash.
Flax .....	—	ditto.
Hemp .....	2 per cent .....	1 per cent and 1 per cent for cash
Licorice .....	net tare, 1 kilo for rope, and 1 per cent.	2 per cent, 1 per cent, and 1 per cent for cash
Pepper .....	5 kilos. per bale ..	2 per cent for cash
Cinnamon .....	1½ kilos per bale, and 1 per cent	1½ per cent for cash
Cloves, mace, plimento, and nutmegs ..	net weight.....	ditto
Ginger .....	9½ kilos per case ..	1 per cent for cash.
Saltpetre .....	net weight and 1 per cent	2 per cent, 1 per cent, and 1 per cent for cash
Wool: Cape .....	3 per cent. ....	1 per cent.
Buenos Ayres ..	6 kilos per bale....	ditto
Kurrachee .....	4½ per cent .....	ditto.

The above are the customary tares and other allowances made by the merchants in their transactions with each other. But in paying the import duties at the custom-house, the tare upon goods paying duty by weight is, with the exception undermentioned, fixed at 15 per cent for such as are in casks or cases made of wood, and at 8 per cent for such as are in packages, canisters, mats, baskets, leather, linen, etc.

**Railroads.** On the first of January, 1879, there were railroads of a total length of 1,693 kilometres, or 1,040 miles, open for traffic in the kingdom. The State owned 815 kilometres, or 509 miles, and private companies 853 kilometres, or 531 miles. The following table gives total length of railroads opened for traffic at that time:—

Railroads.	Length. Kilometres
Private Companies:—	
Dutch-Rhenish .....	210
Rotterdam-Antwerp ..	118
Maestricht-Aachen ..	37
Amsterdam-Rotterdam ..	102
Utrecht-Kampen .....	101
Maestricht-Liëttich ..	29
Almelo-Salbergen .....	55
Eindhoven-Hasselt .....	57
Tilburg-Turnhout .....	31
Nymegen-Kleef .....	27
Neuzen-Gent and Mechelen ..	86
Total, private companies ..	853
State railroads.....	815
Total .....	1,668
In miles.....	1,042

**Colonies.** The following table gives the area and population of the various colonial possessions, divided into three groups: first, the possessions in Asia or the East Indies, secondly, the

West India islands; and thirdly, the colony of Surinam, in South America:—

Colonial Possessions.	Area: English Square Miles.	Population.
1. East Indies:—		
Java and Madura .....	51,324	18,125,269
Sumatra, West Coast .....	46,200	961,187
Benkulen .....	9,576	135,482
Lampungs .....	9,975	117,370
Palembang .....	61,152	508,638
Riau .....	17,325	61,000
Banca .....	4,977	64,257
Billiton .....	2,500	27,287
Borneo, West Coast .....	58,928	395,639
Borneo, S. and E. Districts ..	137,928	898,875
Celebes .....	45,150	399,627
Menado .....	26,600	217,377
Molucca Islands .....	42,420	198,011
Timor and Sumba .....	21,840	900,000
Bali and Lombok .....	3,990	69,148
New Guinea .....	67,410	200,000
Total, East Indies.....	607,293	24,276,638
2. West India Islands:—		
Curaçao .....	160	23,972
Aruba .....	69	5,670
St. Martin .....	13	3,101
Bonaire .....	95	4,470
St. Eustache .....	12	1,869
Saba .....	7	2,002
Total, West Indies.....	356	41,024
3 Surinam .....	59,051	69,329
Total Possessions.....	696,700	24,386,991

The population of the West India islands is after a census taken at the end of 1874, and that of the other colonial possessions—with the exception of Timor and Sumba, Bali and Lombok, and New Guinea, which are only estimates—after enumerations of 1872-1875.

Of the Dutch colonial possessions the East India island of Java, with the adjoining Madura, is by far the most important. Administered as dependencies of Java are the whole of the possessions of *H.* in the East Indies. The kingdom derives a considerable revenue from its colonial possessions, arising from the sale of colonial produce, chiefly coffee and tin. The sales are effected on what is called the Consignation system, carried out through the medium of the Netherlands Trading Company, acting as agents of the government (see *Java*).

**Money.** The *Guilder*, *Gulden*, or *florin* = \$0.385 value of exchange in the United States.—The money in general circulation is chiefly silver; but a bill which passed the States-General in the session of 1875 ordered an unrestricted coinage of ten-guilder pieces in gold.

**Weights and Measures.** *H.* adopted the French metric system of weights and measures in 1820, retaining, however, old designations for the same. Much confusion having arisen therefrom, an act was passed April 7, 1869, establishing from January 1, 1870, a series of new international names of weights and measures, with facultative use, during the first ten years, of the old denominations. The principal new names, together with the old designations, are:—

The <i>Kilogram</i> (Pond).....	= 2 205 lbs avoirdupois.
“ <i>Meter</i> (El) .....	= 3 281 feet.
“ <i>Kilometer</i> (Myl) .....	= 1093 yards, or nearly 5 furlongs.
“ <i>Are</i> (Vierkante Roede) ..	= 119 6 sq. yards, or 0 246 sq. acre.
“ <i>Hektare</i> (Bunder).....	= 2 47 acres.
“ <i>Stere</i> (Wisse).....	= 35 31 cubic feet.
“ <i>Liter</i> (Kan) .....	= 1 76 pints.
“ <i>Hektoliter</i> (Vat).....	= 22 gallons.

All the other French metric denominations are adopted with trifling changes in the new code of names.

**Seaports.** The chief ports of *H.* are Amsterdam, Delft on the Ems, Dordrecht on the Waal, Middelburg and Flushing in the island of Walcheren, Harlingen, at the mouth of the canal of Leeuwarden, in Friesland, and Rotterdam. Of these, the three following are the most important:—

**Amsterdam**, the principal city of *H.*, sometimes called the “Venice of the North,” is situated in lat 52° 22' N, lon 4° 53' E, at the confluence of the Amstel with the V, an arm of the Zuider Zee. Within the city four canals—the Prinsen Gracht, Keizer's Gracht, Heeren Gracht, and the Singel—extend, in the form of polygonal crescents, nearly parallel to each other; while numerous smaller canals intersect the city in every direction, dividing it into about 90 islands, with nearly 290 bridges. Some of these are of stone, but the majority are of iron and

wood, and so constructed as to allow vessels for inland navigation to pass through. Westward of the river Amstel, which passes almost through the centre of the city, is the more modern part, where the houses are often exceedingly handsome, and the streets broad, and planted with rows of large trees between the houses and the canals. The harbor is capacious and secure, admitting the largest vessels close to the quays and docks. At the mouth of the Y there is a bar called the Pampus, to cross which large vessels must be lightened; but this inconvenience, as well as the delays and dangers attending the navigation of the Zuyder Zee, has been obviated by the ship-canal mentioned in page 540. Amsterdam has sugar refineries; soap, oil, glass, iron, dye, and chemical works; distilleries, breweries, tanneries; tobacco and snuff factories. The cutting of diamonds has long been practised in the city by the Jews. Amsterdam is, however, more distinguished by its trade, which, though now somewhat reduced, is still very considerable. A great portion of the trade between Great Britain and H. is carried on with Rotterdam, which is much more conveniently situated for such intercourse than Amsterdam. But the latter continues to engross by far the larger share of the commerce with the flourishing colony of Java, the other Dutch possessions in the East, and with the U. States; and is, consequently, the principal mart on the continent of Europe for Eastern and American produce. The Amsterdam merchants were formerly the most extensive dealers in bills of exchange, and though London is now in this respect far superior to Amsterdam, the latter still enjoys a respectable share of this business.—*Custom-house Regulations.* Captains of ships are bound to make, within 24 hours of their arrival at Amsterdam, or any Dutch port, a declaration in writing of the goods of which their cargo consists. If the captain be not acquainted with the goods of which the cargo consists, they must make their declaration under the general term of *merchandise*, and exhibit the bills of lading along with the declaration. The custom-house officers are instructed to inform the captains of almost all formalities required by law.—The *warehousing system* has been long established in Amsterdam; and all goods, whether for home consumption or transit, may be deposited in bonded warehouses. Speaking generally, goods can only be kept in bonded warehouses for two years; but grain of all kinds may be kept for an unlimited period. The warehouse rent chargeable per month on a quarter of wheat is, on an upper loft, 2½ cents; on an under loft, 3 cents. On a ton (Eng.) of sugar in casks the charge is 16 cents; in bags, 12 cents. The dock and its adjacent warehouses belonging to the *Entrepôt Général*, or establishment for warehousing goods imported by sea, or intended to be re-exported by sea or by the Rhine, are large and commodious. The dock has water to float the largest ships, and the dues and other charges are exceedingly moderate. Merchants may employ their own men or those of the dock in loading or unloading; and may either place their property in separate vaults or floors of which they keep the key, or intrust it to the care of the dock officers.

*Flushing* [Dutch, *Vlissingen*], a fortified seaport town of the province of Zealand, is situated on the island of Walcheren, at the mouth of the estuary of the Western Scheldt, about 50 m. S. W. of Rotterdam. Since 1872 it has had railroad connection with the main lines of Europe; and by the construction in 1873 of a great harbor, docks, and canal works, a communication between it and the North Sea has been opened up for vessels of the largest size. The outer harbor has a surface of 32.11 acres, and a depth at low water of 22 feet; the depth of both the inner harbors at low water is 27 feet; the surface of the one being 16.55 acres and that of the other 11.83 acres. With these works Flushing possesses one of the finest and safest harbors of Europe, and the one of the Dutch coast best adapted for the trade with Germany. Pop. 12,000.

*Rotterdam*, a seaport on the N. bank of the Maas, and the second commercial city of H., is situated in lat. 51° 55' 19" N., lon. 4° 29' 14" E. It is more advantageously situated than Amsterdam, being nearer the sea; and the canals which intersect it are so deep as to admit of the larger vessels coming up to the quays and warehouses of the merchants. Its commerce is yearly increasing, and it is the best market for madder and Geneva. It has a regular and frequent intercourse by steamers with London, Liverpool, Havre, Hamburg, etc.

**Holland**, a kind of linen which, when brown or unbleached, is used chiefly for window-blinds and children's garments; bleached is used for finer purposes.

**Hollands, Geneva, Schiedam, Hollands Gin, Dutch Gin**, a superior kind of gin made in Holland.

The materials employed in the distilleries of Schiedam, in the preparation of this excellent spirit, are 2 parts of the best unmalted rye and 1 part of malted bigg, reduced to the state of coarse meal by grinding. About a barrel (36 galls.) of water; at a temperature of from 162° to 168° F., is put into the mash-tun for every 1½ cwt. of meal, after which the malt is introduced and stirred, and, lastly, the rye is added. Powerful agitation is next given to the magna till it becomes quite ui-

form, when the mash-tun is covered over with canvas, and left in this state for two hours. Agitation is then again had recourse to, and the transparent "spent wash" of a preceding mashing is added, followed by as much cold water as will reduce the temperature of the whole to about 85° F. The gravity of the wort at this point varies from 33 to 38 lbs. A quantity of the best pressed Flanders yeast, equal to 1 lb. for every 100 galls. of the mashed materials, is next stirred in, and the whole is fermented in the mash-tun for about 3 days, or until the attenuation is from 7 to 4 lbs. (sp. gr. 1.007 to 1.004). During this time the yeast is occasionally skimmed off the fermenting wort. The wash, with the grains, is then transferred to the still, and converted into "low wines." To every 100 galls. of this liquor 2 lbs. of juniper berries (3 to 5 years old), and about 1 lb. of salt, are added, and the whole is put into the low-wine still, and the fine spirit drawn off by a gentle heat, one receiver only being employed. The product per quarter varies from 18 to 21 galls. of spirit, 2 to 3 o. p.—2 (*Best Hollands*.) Hollands rectified to the strength of 24° Baume (sp. gr. .9125, or about 6 o. p.).—3 (*English-made*.) From juniper berries (at least a year old, and crushed in the hands), 3 lbs.; rectified spirit, 1½ gall. (or proof spirit, 2½ galls.); digest, with agitation, for a week, and then express the liquor; after 24 hours' repose, decant the clear portion, add it to good corn spirit, at 2 or 3 o. p. overproof, 90 or 100 galls., and mix them well together. The last form, which is only given as example, produces a very pleasant spirit. If it is kept for some time to "mellow." Age is one of the principal causes of the "creaminess" of Dutch gin, which usually lies in bond for some time before being consumed. The product is, however, much superior if the ingredients are rectified along with 20 galls. of water, and about 14 lbs. of salt, by a gentle heat. It will be seen from the above that the superior flavor of Hollands spirit depends more on the peculiar mode of its manufacture than on the quantity of juniper berries employed: 2 lbs. of them, when new, being barely equivalent to 1 oz. of the essential oil; and when old, to less than ½ oz., a quantity wholly insufficient to flavor 100 galls. of spirit. The Dutch distillers most noted for this liquor add a little pure Strasburg turpentine and a handful or two of hops to the spirit, along with the juniper berries, before rectification. The former substance has a pale yellowish-brown color, and a very fragrant and agreeable smell, and tends materially to impart that fine aroma for which the best Geneva is distinguished. At Rotterdam sweet-fennel seed is commonly added as a flavoring; and at Weesoppe Strasburg turpentine and fennel seeds, or the essential oil of fennel, are frequently substituted for a large portion of the juniper berries. Schiedam Hollands is considered the best: the next quality is that of Rotterdam; after these comes that of Weesoppe. *Imp.* duty same as alcohol. See GIN.

**Hollow**, that contains an empty space; cavernous; concave; sunken; empty; void; evacuated in the interior.

**Hollow Girder**, an iron girder not solid.

**Hollowing-Knife**, a drawing-knife, used by coopers for working on concave surfaces.

**Hollowing-Plane**, a carpenter's plane, having a round, convex sole.

**Hollow Rail**, a tubular railroad rail which has been steam-heated to prevent the accretion of snow and ice.

**Hollow-Ware**, a general trade-name given to various kinds of culinary and other vessels made of iron. Some are made of wrought-iron by stamping; some by riveting pieces together; some by casting in moulds. These vessels may be left in the plain metallic state, or may be blackened on the outside by a kind of Japan. The interior in cheap ware is left untouched, but the better kinds are either coated with tin, nearly in the same way as tin plate, or with enamel (see ENAMEL). *Imp.* duty: glazed or tinned, 3½ cts. per lb.

**Holly**, a small tree or shrub of the genus *Ilex*. The wood of the European *H. (Ilex aquifolium*, Fig. 271) is almost of an ivory whiteness, except near the centre of very old trunks, when it is of a brownish hue. It is very hard and compact, with a fine grain, and susceptible of a high degree of polish, which renders it well adapted for many purposes in the arts. When dry, it weighs 47½ lbs. to a cubic foot, and is very retentive of its sap, in consequence of which it is liable to warp, unless it is well dried and seasoned before being used. It readily takes a durable color of almost any shade, and hence it is much

used by cabinet-makers in forming what are technically called "strings and borders" in ornamental works. When properly stained black, its color and lustre are little inferior to those of ebony. It may be applied to a great number of purposes by joiners, cabinet-makers, turners, engineers, mathematical instrument makers, and next to the box and pear-tree it is the best wood for engraving upon, as it is compact, and stands the tool well. Among its principal uses in Europe at present is, when dyed black, to be substituted for ebony, in the handles of metallic teapots, etc. In France the young shoots and the branches are given to sheep and deer during winter; and the stronger straight shoots, deprived of their bark, are made into whip-handles and walking-canes. The bark of the *H.* contains an abundance of vis-

Fig. 271. — HOLLY.

cid matter; and when macerated in water, fermented, and then separated from the fibres, it forms bird-lime. Medicinally, the bark of this tree is mucilaginous, emollient, and solvent, and is said to possess strong febrifugal powers. The berries are purgative, and 6 or 8 of them, when swallowed, will cause violent vomiting; though they are considered as poisonous to men, they form the food of some birds, more especially of the thrushes. — The wood of the American *H.* (*Ilex opaca*) resembles that of the European species, except that it is rather browner at the heart. It is compact, heavy, of a fine grain, and is susceptible of a brilliant polish. Its principal use is for inlaying mahogany furniture, and for turning into small boxes for druggists, and for small screws. When perfectly seasoned, it is very hard and unyielding, which renders it well adapted for pulleys used in ships. It may be dyed of various colors, so as to resemble many foreign woods. The bark may be employed for making bird-lime, in a similar manner as that of the preceding species. Medicinally, it is emetic and cathartic.

**Hollyhock**, a tall-stemmed plant (*Althea rosea*) with a gaudy flower, cultivated in gardens; the flowers are mucilaginous and demulcent, and the leaves dye blues.

**Holometer**, a mathematical instrument for

taking measures both on the earth and in the heavens.

**Holstein cattle**. See CATTLE (NEAT).

**Holster**, a leather case for pistols fixed at the saddle of a horseman.

**Holy-Stone**, a large stone, used with sand, for scouring a ship's decks by hand. It receives its name from the unwillingness of sailors to submit to the drudgery of using it.

**Holy-water Pot**, an ornamental vase, used to keep holy water in churches, etc.; a benitier.

**Homard** [Fr.], a lobster.

**Home**, in naval language, is said of anything that is close in its place; it is applied to the sheets of the sails, the shot and cartridge in a gun, and any article of stowage.

**Home**, a fire-insurance Co., located in New York City, organized in 1853. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$3,000,000; net surplus, \$1,363,488.94; risks in force, \$344,131,435; premiums, \$3,461,353; premiums received since the organization of the Co., \$45,887,470.88; losses paid, \$28,487,370.23; cash dividends paid to stockholders, \$4,615,000.

**Home**, a fire-insurance Co., located in Newark, N. J., organized in 1873. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$200,000; net surplus, \$9,858.58; risks in force, \$5,573,784; premiums, \$56,179.17; premiums received since the organization of the Co., \$299,070.62; losses paid, \$121,621.66; cash dividends paid to stockholders, \$62,000.

**Home-Brewed**, beer made at a private house; not purchased from a brewery.

**Homespun**, spun or wrought at home; of domestic make or manufacture.

**Homestead**, a farm with the land immediately adjoining.

**Home-Trade**, ships: in the English official returns these comprise ships trading on the coasts of Great Britain and Ireland, or to the continental ports between the limits of the River Elbe and Brest.

**Homeward-Bound**, on the way home.

**Hominy**, Indian corn coarsely ground or broken. The cuticle and germ of the shelled corn are removed by the grating or beating action of a machine (*H.-mill*), which also breaks as small as may be wanted. The sizes are graded by sifting.

**Homœopathic Medicines**, infinitesimal medicines, prepared and used upon the great principle of *homœopathy*, viz., *Similia similibus curantur*, to which *allopathy* is antagonistic.

**Honduras**, a republic of Central America, lying between Lat. 13° 10' and 16° N.; lon. 83° 11' and 89° 30' W.; and bounded N. and E. by the Bay of *H.* and the Caribbean Sea, S. by Nicaragua, and N. W. by Guatemala; area, 58,168 sq. m. The republic is divided into 13 departments, with a total population of 400,000. Both area and population are only known through estimates, no enumeration having as yet taken place. The bulk of the inhabitants consists of aboriginal Indians, and the sparse European-descended population, mainly of Spanish origin, is in the small ports of the Pacific coast, and in the town of Santa Rosas, in the tobacco districts of Gracias. The capital is Tegucigalpa, with 12 inhabitants. *H.* is governed under a charter proclaimed in November, 1855. There is a chamber of deputies of 37 members, but no senate, in lieu of which latter ten counselors are appointed by the government to act as advisers, and convened at the president's pleasure. The judicial authority is vested in two chief justices, one of whom resides in the present capital,

and the other in the former capital, Comayagua. The president is elected for four years.

The ports of *H.* on the Atlantic side are Truxillo, Omoa, and Puerto Cortez. On the Pacific, in the Bay of Fonseca, the republic has ten ports, San Lorenzo and the free port of Amapala, on the island of Tigre, which has a fine anchorage and salubrious climate. The republic has a coast-line of 400 m. on the Bay of *H.* and the Caribbean Sea, and 60 m. on the Bay of Fonseca, on the Pacific side. The rivers are numerous, and some of them of large size. The Chamelicon, Ulua, Aguan or Roman, Tinto, Patuca, and Segovia, falling into the Atlantic, and the Choluteca, Macaome, and Guasoran, falling into the Bay of Fonseca, are the principal. In physical character, climate, and production, *H.* resembles Guatemala. See GUATEMALA.

For a long time the finances of *H.* have been in a great disorder owing to prolonged civil strife, aggravated in 1872 by wars with Guatemala and San Salvador, which continued with short interruption till the end of June, 1876, when exhaustion on all sides brought about a peace. The national foreign debt, amounting to \$29,950,540 at the beginning of 1877, consisted of 3 loans: the first, contracted at the London Stock Exchange in 1867, of \$5,000,000; the second, issued in London and Paris in 1868, for the nominal amount of \$12,450,540, and the third, negotiated in London in 1870, for the nominal amount of \$12,500,000. The first and third loans were at 10 per cent, and issued at the price of 80, and the second loan was at 6 per cent, and issued at 75. All the loans were raised for the professed object of constructing an inter-oceanic railroad from Puerto Cortez, on the Pacific, to the Bay of Fonseca, 232 m. in length. The interest in arrear on the three loans amounted to \$6,150,820 in 1876. *H.*, however, seems to have entered on the career of civilization in the highest sense of the term under the administration of Don Marco Aurelio Soto, who was elected president, May 29, 1877. It is reported that a satisfactory arrangement has been made with England in regard to the national debt; and the national revenue, which never exceeded \$375,000 under former administrations, is said to have reached \$800,000 in 1878. The inter-oceanic railroad is now in operation from Puerto Cortez to San Pedro Sula, a distance of about 90 m. The value of the rolling-stock is estimated at \$500,000, and the entire cost of the road is given at \$2,000,000. There were 750 m. of telegraph at the beginning of 1879, and 500 m. additional were in process of construction. A contract for a line of bi-weekly steamers to Cuba was signed in 1878, and extensive concessions of land have been made to North America for the cultivation of coffee, cocoa, and other staples, on a scale hitherto unthought of in those regions. Lastly, it is reported on trustworthy authority that a combination is set on foot in the U. States for the purpose of establishing a North American banking, exchange, and commission business in the capital of *H.*, which enterprise would soon remove the chief impediment to the extension of commerce between the two countries.

The exports of *H.* consist chiefly of mahogany, hides, tobacco, cattle, and indigo, the total value being estimated at about \$1,000,000 per annum, while the imports comprise cotton goods, silks, and hardware. There are no official returns of the value of either the imports or exports, owing partly to the customs at the principal ports being farmed out to individuals whose interest it is to conceal all facts concerning their revenue. The commerce is mainly with Great Britain, the U. States, and Spain, but the value of the trade with this country is not given in the annual statement issued by the Secretary of the Treasury Department, which merges *H.* into "Central America." See GUATEMALA.

Mr. J. J. Valentine, Special Commissioner of the Republic of *H.*, while in New York in 1879, stated as follows the object of his commission to the U. States: "It is to show that, geographically, the Republic of *H.* is the key to Central American trade, and that, therefore, it offers inducements of a peculiar nature to American commerce. In cultivating commercial relations between the two republics, great advantages must result to both, and immense profits accrue to the American merchants and manufacturers who appreciate the fact and act accordingly. Goods taken down there may be readily exchanged for the rich marketable products of the country, including the precious metals and high-grade mineral ores. Of the Rosario mines, which offer great inducements to investment, the most noted is situated at a distance of only 27 m. from Tegucigalpa, the capital of *H.* It is at present worked by the imperfect method known to the natives, which is, of course, far behind the processes used in the U. States. By the present method the ores yield about \$100 per ton, whereas, according to assays made by smelting companies here, they can, by the aid of proper machinery, be made to pay from \$150 to \$4,000 per ton, and 30 or 40 times the amount of ores now extracted could be taken out. Dr. R. Fritz Gaertner, lately of the office of the State Geologist, of Albany, and who is now at the head of the geological and mineralogical departments of the *H.* government, calculates that at the Rosario mining district there are visible on the surface veins of sufficient magnitude to require at least 150 years to exhaust them. According to his estimates a single company, whose claim is already in working order, will

net a dividend of something like \$1,000,000 annually. I speak of these mines to show the fine field which *H.* offers in this branch to American industry. There are several other interests equally inviting to intelligent labor. The balance of exchange in products as between Central America and the U. States is in favor of the former in the proportion of seven to one, while, in fact, it should be the reverse. Europe supplies the great bulk of merchandise to those countries, and it is found by experience that while America is represented by a small fraction of goods imported to Central America, that fraction is undeniably of far better quality than that which comes from the Old World. Now, as the distance between this country and Central America is much shorter than between the latter and Europe, it is reasonable to suppose that America should step in and make this remunerative trade her own. I need not say that the capital and skilled labor of the U. States which are seeking remunerative employment would find a ready market for their commodities in *H.* Agriculture and mining there offer inducements superior to any other Central or South American country, under particularly favorable climatic conditions and liberal laws, and I am empowered by the government to make concessions of valuable coffee and other agricultural lands, with the simple provision that the grantees settle upon them within a reasonable time. I purpose returning shortly to *H.*, and will take with me a committee consisting of Captain Charles P. Dahlgren and Captain Peter Hagan, the latter of Albany. These gentlemen will examine and report upon the mineral and agricultural lands which I am empowered to offer. The new constitution of *H.* guarantees to the emigrant and his personal effects exemption from import duties, also the free importation of implements and instruments necessary to the exercise of his calling, besides the enjoyment of the same civil and religious prerogatives as are enjoyed by the people of the country. They will be granted the right to vote, exemption from taxes and contributions of all kinds, as well as exemption from military service and perfect liberty in the exercise of their religious faith. No instance can be cited wherein the person or property of foreigners has been molested, unless they mixed too much in politics. The foreigner and his goods have always been considered sacred by belligerent parties. Through the worst periods in Central American history Europeans have traded unmolested, and I can cite half a dozen houses in Tegucigalpa alone that enjoy an almost unlimited European confidence. I can speak confidently for *H.* in saying that war times have passed for Central America. By a liberal and intelligent policy the present government has succeeded in gaining the confidence of the people, and no public disturbance of any kind need now be apprehended. President Soto is so popular and progressive in his ideas that peace and progress may naturally be looked for throughout the land. He has established a system of public schools, with teachers from the U. States; he has built telegraphic lines, opened up mail communication in the republic, and advanced its condition far beyond anything it had formerly attained. No part of the country is more unhealthy than the Mississippi Valley, and the marshy district occupies relatively a much smaller territory. Tegucigalpa, the present capital of *H.*, derived its name from the Indian words 'Tagus-galpa,' meaning mountain of silver, which is characteristic of the district where it is situated. The minerals that can be most profitably worked in *H.* are gold, silver, copper, iron, lead, coal, and opals, and the vegetables are generally those of the temperate and tropical regions. The cultivation of coffee is an immensely remunerative branch of industry. Then there are hides, furs, gums, oils, resins, and precious woods that can be exported in abundance. I have here a small number of samples of the products of the country which American merchants can examine when they desire. I expect that the first vessel will soon sail to the north coast of *H.* with implements and goods for the country, and the government will do everything that can be accomplished to facilitate the growing trade with American merchants." It is scarcely necessary to remark that the above lines, coming from a native writer, whose object was to promote emigration to *H.*, may contain a too favorable view of that Central American country. On some points Mr. Valentine may have taken his patriotic aspirations for actual facts; but *H.* is still so little known, that it would be difficult either to endorse or criticise the statement of the Hondurian commissioner.

**Honduras (British)** is a British colony occupying a portion of the peninsula of Yucatan, on the W. coast of the Caribbean Sea, between lat. 15° 55' and 18° 30' N.; lon. 88° 5' and 89° 45' W. The boundaries of the colony are Mexico on the N., on the S. Guatemala and the river Sarstoon, on the W. Guatemala, on the E. the Caribbean Sea. Its extreme length is 158 m., and its extreme width 60 m., with an area of about 6,400 sq. m., and population (1877) 26,000, of whom only 390 are whites. The country is generally flat and swampy on the coast, but rises gradually towards the interior, where the Coxcomb mountains rise to a height of

4,000 feet. In 1850, when the Clayton-Bulwer Treaty was under discussion, it was stipulated that the promise of Great Britain not to colonize or occupy Nicaragua, Costa Rica, and the Mosquito territory, or any part of Central America, did not apply to the settlement of British Honduras. In the forests are found the cedar, mahogany, rosewood, pine, and other useful timber, the india-rubber and gutta-percha trees, with the sarsaparilla, agave, indigo, and numerous useful plants and shrubs. The cocoa-nut flourishes on the coast. The usual varieties of tropical fruits, cereals, and vegetables yield abundantly, and the rich soil of the valleys and lower plains produce luxuriant crops of sugar-cane. About 2,500 tons of sugar are yearly exported. The commerce is chiefly with Great Britain.

**Belize**, the capital and only town of the colony, stands on a low flat shore immediately open to the sea, and guarded by numerous small islands, densely covered with trees and shrubs, and so similar as to render the navigation extremely difficult. It is further divided into two parts by the river, which is crossed by a substantial wooden bridge of 220 feet span and 20 feet in length. The part of the town which is situated upon the S. bank of the river is completely insulated by a canal on its W. side, which runs across from a small arm of the sea, and bounds the town on its S. side. The whole town is embowered in groves and avenues of the cocoa-nut and tamarind trees. Fort George is situated about half a mile from the river, on a small low islet. In the neighborhood of Belize the natural heat of the climate is tempered by the sea-breezes that prevail during nine months in the year, so that, even in the hottest season, the thermometer seldom rises above 83° F. and during the wet season it sinks to 60°. In June, July, August, and September, heavy and frequent rains fall, and these are the most unhealthy months of the year, from the decomposition of animal and vegetable matter in the adjacent lowlands and swamps. Pop 6,614.

**Hone**, a whetstone; a talcky slate-stone, wrought into the form of straight slabs, and used for whetting or sharpening the edges of tools after they have been ground. There are different kinds of hones, most of which are moistened with oil when used, and are hence called *oil-stones*.

They consist, chiefly, of the following: 1. *Norway rag stone*, the coarsest variety of the hone-stones; it gives a finer edge than the sandstones. 2. *Charnley Forest stone*, which is used as a substitute for Turkey oil-stone. 3. *Ayr stone*, *Scotch stone*, or *slate-stone*, used for polishing marble and copper plates, but the harder kinds for whetstones. 4. *Idwall*, or *Welsh oil-stone*, used for small articles of cutlery. 5. *Devon shire oil-stone*, for sharpening thin-edged broad tools. 6. *Cutlers' green-stone*, from Snowdon, which is very hard and close, and is used for giving the last edge to lancets, etc. 7. *German razor-hone*, used almost entirely for razors. It is obtained from the slate mountains near Ratisbon, where it forms a yellow vein in the blue slate. It is sawn into thin slabs, and cemented to a slab of slate, which serves as a support. 8. *Blue polishing-stone*, a dark slate of uniform texture, used by workers in silver and some other metals for polishing off the work. 9. *Gray polishing-stone*, somewhat coarser than the blue. 10. *Welsh clearing-stone*, a soft variety of hone-stone used by cutters for giving a fine edge to their broad knives. 11. *Peruvian hone*, for sharpening large tools. 12. *Arkansas stone*, from North America. 13. *Bohemian stones*, used by jewellers. — *Turkey oil-stone* is superior to every other substance as a whetstone; it will abrade the hardest steel, and is sufficiently compact to resist the pressure required for sharpening a graver. The black variety is somewhat harder than the white. These stones are imported from Turkey in irregular masses, seldom exceeding 3 inches square and 10 inches long, and are rut up by means of the lapidary's splitting-mill and diamond-powder, then rubbed smooth with sand or emery on an iron plate, inlaid in wood, and secured by glazier's putty. Sperrin or neat's-foot oil, or some oil which does not readily thicken, should be used with them. Oil-stone powder is used for grinding together the brass or gun-metal fittings of mathematical instruments, and also instead of pumice-stone for polishing superior brass-work. *Imp. free.*

**Honey** [Fr. and Sp. *miel*; Ger. *Honig*; It. *mele*], a vegetable juice collected by bees. It varies according to the nature of the flowers from which it is collected. Thus, the *H.* of Minorea, Narbonne, and England are known by their flavors; and the *H.* prepared in different parts even of

the same country differs. It is separated from the comb by dripping and by expression: the first method affords the purest sort, the second separates a less pure *H.*; and a still inferior kind is obtained by heating the comb before it is pressed. When obtained from young hives, which have not swarmed, it is denominated *virgin H.* It is sometimes adulterated with flour, which is detected by mixing it with tepid water, the *H.* dissolves, while the flour remains nearly unaltered. Bee-keeping is a branch of agriculture of great importance in some of our States, but as few bee-keepers keep an account of the product of their hives, the returns of the yield of *H.* are very imperfect. The average yield of *H.* throughout the U. States is 22.8 pounds per hive. The average price is 20 to 25 cents per pound. Considerable quantities of *H.* are imported from the West Indies, chiefly from Cuba. *Imp. duty*, 20 cts. per gallon.

In *Pharmacy*, *H.* are minor preparations, now almost superseded by sirups.

**Honeycomb**, the waxen cells made by bees in their hive, for depositing their honey, forming, when purified, the beeswax of commerce (see BEESWAX). — A flaw in a metallic casting.

**Honey-Dew**, a kind of tobacco which has been moistened with molasses.

**Honey-Sugar**, the saccharine principle of honey, extracted from flowers and flowering shrubs by bees.

**Hong**, a trading factory at Canton; a mercantile house. — One of a class of licensed merchants, who had, until of late years, the monopoly of foreign trade at the chief Chinese ports.

**Hong-Kong**, a British colony, consisting of an island situated off the S. E. coast of China, at the mouth of the Canton River, in lat. 22° 15' N., lon. 114° 11' E. It is about 8 m. long and 5 wide, and comprises, with Kowloon, an area of 32 sq. m., and a population of 124,198, of whom 5,931 are whites (133 from the U. States), 2,823 Indians, and 115,444 Chinese. It is separated from the mainland of China by the narrow strait of Ly-ee-moon Pass. *H.-K.* is one of those islands called by the Portuguese "Ladrones," or "Thieves," from the notorious habits of its old inhabitants. The colony, which is described as exceedingly beautiful, possessing one of the finest harbors in the world, surrounding picturesque hills rising between 1,000 and 2,000 feet high, is a military and naval station for the protection of British commerce, and it is the centre of trade in many kinds of produce. — chiefly opium, sugar, flour, oil, amber, cotton, ivory, betel, sandal-wood, rice, tea, woollens, silks, salt, etc. *H.-K.* has neither agriculture nor manufactures, and produces little. It possesses, however, excellent docks, capable of holding the largest vessels. The city of Victoria faces the anchorage, and the cession in 1860 by the Chinese of a part of the mainland on the opposite shore, called the Peninsula of Kowloong, places both sides of the harbor under British jurisdiction.

The prosperity of *H.-K.* is the result of its establishment as a free port at the gates of China. The number of foreign vessels trading regularly from *H.-K.* is considerable, but the annual aggregate is swollen by the number of small vessels under the Hanseatic and other European flags, which make short coasting voyages. These monopolize in a great measure the carrying trade of pulse and bean-cake from the northern to the southern ports of China, and the transport of camphor and other products of Formosa. The rapid development of steam traffic tends to interfere with the larger sailing vessels, though at certain seasons considerable employment is found for the latter in the transport of rice from Indian and Burmese ports to *H.-K.* The emigration of Chinese to California employs a respectable amount of tonnage. Several great and competing steam-lines connect *H.-K.* with San Francisco and Europe. Daily steamers connect *H.-K.* with Canton.

No port charges of any description are levied upon European vessels. A copy of the harbor regulations is presented to the master of every merchant vessel on her entering the port. The method of conducting business at *H.-K.* is precisely similar to that at Canton. See *CHINA* (Canton).

The commercial intercourse of *H.-K.*—virtually a part of the commerce of China—is chiefly with Great Britain, the U. States, and Germany, Great Britain absorbing about one half of the total imports and exports. There are no official returns of the value of the imports and exports of the colony from and to all countries, but only mercantile estimates, according to which the former averages \$20,000,000 and the latter \$10,000,000.

The commerce of *H.-K.* with the U. States is considerable. For the year 1878 the value of the imports from this country was \$8,591,153, and the exports to the U. States \$2,232,663. The principal articles of imports and exports were as follows: *Imports*: Books, etc., \$10,219; wheat and wheat flour, \$1,-

Besides the above weights and measures of China, those of Great Britain are in general use in the colony.

**Honiton Lace**, a pillow or cushion lace made in Devonshire, England, remarkable for the beauty of its figures and sprigs, which are sewed on to net by the needle.

**Honley**, a woollen fabric made chiefly of shoddy.

**Honolulu**. See *HAWAIIAN ISLANDS*.

**Hoobaballi**, a close, fine-grained wood of Guiana. It is easily worked, and takes a high polish.

**Hood**, a slight covering for the head, worn by females.—Any covering resembling a hood, or answering the purpose of a hood, as the head of a

Fig. 272. — CHINESE MOSQUE.

217,661; clocks, \$26,489; copper in bars, \$10,723; drugs, etc., \$20,261; fruits in cans, \$22,097; ginseng, \$454,037; gold and silver bullion, \$1,481,664; gold coin, \$127,912; silver trade dollars, \$3,733,943; lead, \$256,168; mineral oil, \$98,125; cured fish, \$268,011; potatoes, \$11,797; quicksilver, \$780,323; scales, \$13,905. — *Exports*: Camphor (938,975 lbs.), \$140,339; chemicals, \$17,851; volatile oils, \$42,666; raw silk, \$36,002; tea (805,475 lbs.), \$145,064; rice, \$35,787; china ware, \$32,614; spices, \$230,200; straw and palm-leaf (manuf.), \$441,608; brown sugar (19,322,706 lbs.), \$850,657; cabinet ware, etc., \$10,245.

In 1878, 13 American sailing vessels (tonnage 60,992) and 12 steamers (tonnage 54,966) entered, and 45 American sailing vessels (tonnage 83,206) and 11 steamers (tonnage 21,922), cleared the harbor of *H.-K.*

**Money**. The Mexican dollar of 100 cents = \$1.015 is the only legal tender of payment for sums above 200 cents; but silver dollars, bearing the effigy of the British sovereign, are issued from the *H.-K.* mint.

#### Weights and Measures —

The <i>Tael</i> .....	=	1½	oz. avoirdupois
" <i>Peul</i> .....	=	133	lbs. "
" <i>Catty</i> .....	=	1½	lbs. "
" <i>Chih</i> .....	=	14½	inches.
" <i>Chang</i> .....	=	11	feet.

carriage.—A companion-hatch, sky-light, etc.—A young seal.

**Hooding**, a piece of rough leather, connecting the hand-staff and swingel of a flail.

**Hooding-Ends**, the ends of planks which fit into the rabbets of the stem and stern posts of a ship.

**Hoof**, the horny protection that covers the feet of many domestic and wild animals, as the horse, ox, deer, etc. They are largely employed in making the coarser kinds of handles, combs, and buttons; and chemically they are found to be the cheapest substance from which prussiate of potash can be obtained. *Imp. free*.

**Hoo-hoo**, a piece of checked cotton, used in the African trade.

**Hook**, a piece of iron, or other metal, bent into a curve for catching, holding, or sustaining anything.—An instrument to cut or lop with; a sickle; as a reaping-hook, a bill-hook.—That part

of a hinge which is fixed or inserted in a post or upright. — A forked timber placed on the keel of a ship. See **Fish-Hook**.

**Hookah**, an East Indian pipe, of several parts; the bowl is of silver, shell, earthenware, etc.; the stem, or tube, of cocoa-nut, or some other wood, which a snake, or pliable ornamental tubing, lengthens out into several coils, and the smoke passes through a glass water-vase, while the mouthpiece is of amber, silver, etc.

**Hook-and-Eye**, metal catches, for fastening into each other. They are bent and cut in a press. *Imp. duty*, according to material.

**Hook-Ladder**, a small ladder with hooks at the top.

**Hoondee**, an East Indian draft or bill of exchange, drawn by or upon a native banker or shroff.

**Hoop**, a circular band of wood or metal, used to confine and hold together the staves of casks, kegs, tubs, etc. — A circular framework of some elastic material, as whalebone, steel, etc., used for expanding the skirt of a woman's dress.

**Hooping**, in founding, the iron-work around a moulding-box.

**Hoop-Iron**, flat, thin bar-iron.

**Hop** [Fr. *houblon*; Ger. *Hopfen*; It. *lupolo*; Sp. *lupulo*, *oblon*]. The hop-vine (*Humulus lupulus*) is a native of Europe, and is probably also indigenous in North America, as it has been found growing apparently wild on the banks of the Mississippi and Missouri. It is extensively cultivated for its strobiles, or cones, so largely employed in the preparation of malt liquors. These strobiles, or female catkins, when fully ripe, are picked from the vines and dried in kilns. Hops consist of thin, translucent, veined, leaf-like bracts or scales, of a greenish-yellow color, having near their base two small, round, dark seeds. Hops are somewhat narcotic, and their odor fragrant, the taste bitter, aromatic, and slightly astringent. These properties are owing to the presence of a peculiar resinous secretion in the glands, which has been called "lupulin." Ale and porter owe their bitter flavor and tonic properties to the hops added to them during the process of brewing, — about one pound of hops being added for every bushel of malt. After the hops have been picked and dried, the brightest and finest are put into pockets or fine bagging, containing about 180 lbs., and the brown into coarse or heavy bagging. The former are chiefly used in the brewing of fine ales, and the latter by the porter brewers. A pocket of hops, if they be good in quality, well cured and tight trodden, will weigh about 1½ cwt.; and a bag of hops will, under the same conditions, weigh about 2½ cwt. If the weight of either exceeds or falls much short of this medium, there is reason to suspect that the hops are of an inferior quality, or have been badly manufactured. The brighter the color of the hops, the greater is the estimation in which they are held. The fine flavor or aroma of hops does not exist a year. Beyond that time they become *old hops*, and are sold at a much cheaper rate. A year or two longer, and the bitter itself disappears, and the whole becomes nothing better than chaff. A considerable and gratifying increase has taken place in the last few years in the culture of this useful article in the U. States, chiefly in New York and Wisconsin. In 1868 we had to import from Europe 3,270,995 lbs. of hops, valued at \$859,316; while in 1878, notwithstanding the immense increase in the manufacture of beer, and the consequent increase in the consumption of hops, our export of hops (chiefly to England) amounted to

18,458,782 lbs., valued at \$2,152,873. American hops are packed in bags containing 200 lbs. *Imp. duty*, 5 cts. per lb.; roots for cultivation, free.

**Hop-Hornbeam**, a name for the iron-wood (*Ostrya Virginica*).

**Hope**, a fire-insurance Co., located in New York City, organized in 1856. *Statements*, Jan., 1879: Cap. stock paid up in cash, \$150,000; net surplus, \$15,908.52; risks in force, \$6,138,011; premiums, \$35,454.51; premiums received since the organization of the Co., \$1,951,708.14; losses paid, \$1,210,428.53; cash dividends paid to stockholders, \$200,500.

**Hop-Oast**, a kind of kiln for drying hops.

**Hopper**, a wooden trough or funnel, through which grain passes into a mill to be ground: so called from its *hopping* or leaping motion. — A basket or utensil in which seed-corn is carried for sowing. — In the glass-trade, a conical vessel, suspended from the ceiling, containing sand and water for the use of the cutter. — A box with a bottom in the form of an inverted truncated pyramid, with a trap-door for closing the opening, used for weighing grain and other articles. When full the trap is opened and the contents allowed to run out.

**Hopple**, a mode of fettering the fore-legs of animals to prevent them from straying.

**Hop-Pole**, a pole, or upright, set annually in the ground at the roots of hop-plants for their stems to twine around. When a hop-plantation is first made, as the plants are weak the poles are not required to be more than 5 or 6 feet in length, but in the third or fourth year they require to be 10 or 12 feet in length. Any kind of young trees or saplings may be used as hop-poles; but the most durable are those of the oak, the ash, the sweet-chestnut, and the larch.

**Hordeine**, the starchy matter of barley.

**Horehound**, a wild herb, the *Marrubium vulgare*, which has long been a popular remedy in chronic pulmonary complaints, etc.

**Horizontal Water-Wheel**, a wheel (Fig. 173) running on a vertical axis, and having radial floats shaped so as to present a concave and oblique surface to the stream of water dashed upon them

Fig. 273. — HORIZONTAL WATER-WHEEL.

from a great elevation. This form of wheel is useful in places where there are not better mechanical appliances at hand.

**Horloger** [Fr.], a maker or vender of clocks and watches.

**Horn** [Fr. *corne*; Ger. *Horn*], a substance too well known to require any description. The H. of various animals, chiefly those of the ox, cow, bison, buffalo, chamois, antelope, goat, and sheep,

are manufactured into a great variety of useful forms.

The manufacturer first detaches the *H.* from the bony core by macerating the *H.* in water for a month or six weeks, when the membrane by which the *H.* is attached to the core putrefies and allows the two to be separated. The ash of the cores makes excellent cupels for the assay of gold and silver. The solid tips of the *H.* are sawn off, and are used for handles for knives, for buttons, etc.; the other portion of the *H.* is cut into short lengths, or soaked whole in boiling water, or heated at a fire, the effect of which is to soften it, and allow it to be spread out nearly flat. The *flats* are next pressed between warm and greased iron plates, the pressure varying according to circumstances. If intended for lanterns, the pressure is continued until the *H.* separates into distinct plates; these are placed on a board covered with hide, and scraped with a knife having a wire edge. Some of the shavings which come off are sometimes dyed and cut into various forms, and are so sensitive as to curl up by the warmth of the hand. They are sold at toy shops under the name of "sensitive leaves." After the scraping, the sheets of *H.* are polished with a woollen cloth dipped in charcoal dust and water, next with rotten-stone, and lastly with *H.*-shavings. The effect of heat and pressure on light-colored *H.* is to render it transparent; but most of the articles made of *H.* are colored artificially by boiling the *H.* in infusions of coloring matter. If the *H.* be intended for combs, the pressure must be moderated or the teeth will be brittle; if intended for drinking-cups, the *H.* is cut into lengths, scalded, roasted, and moulded in a cone of wood, and a wooden plug is driven into it for pressing the *H.* into the required shape. After this the cup is turned and polished at the lathe, and a groove is cut to receive the bottom; this being cut out of a flat piece of *H.* by means of a crown-saw, and the bottom of the cup having been softened at the fire, the disk is forced into the groove, and the *H.* contracting in cooling makes a water-tight joint. For knife-handle and similar works the *H.* is cut nearly to the required form, and is moulded in dies with the assistance of heat and a powerful screw-press. The work is finished by scraping and buffing with Trent sand and oil, or rotten-stone and oil. *H.* is sometimes used as a vehicle for applying polishing powders to the flat works of the watchmaker. *H.* easily takes color throughout its entire substance by boiling in colored infusion. An imitation of tortoise-shell is produced by heating *H.* with a hot solution of dragon's blood, litharge, and pearl-ash, applied to those parts which are to be reddish brown, but not to those which are to be yellow. The parings, turnings, filings, and other fragments of *H.*, like those of tortoise-shell (see TORTOISE-SHELL), can easily be softened, and worked up into useful and ornamental forms by pressure. Even if this is not done, nothing need be wasted, seeing that the manufacturing chemist can obtain useful substances by decomposing the *H.* The actual waste in manufacturing is becoming less and less.

The value of horns, horn-tips, and hoofs imported in the year 1873 was \$378,850. *Imp. duty*: unmanufactured, free; *H.* strips and tips, free; *H.* combs (see COMBS); *manuf. of H.*, 35 per cent.

**Horn**, a musical wind-instrument, made originally of horn, but now of metal, mostly of brass. There are many forms of horns, known under various names; as, a trumpet, a cornet-à-piston,

Fig. 274. — SAX-HORNS.

an ophicleide, a trombone, a hunting-horn, a bugle-horn, etc. The Sax-horns, three of which are represented in Fig. 274, are made *en suite*, so as to take in a concerted piece of music the different parts of soprano, contralto, tenor, bass, double-bass, etc. *Imp. duty*, 30 per cent.

**Hornbeam**, the wood of the *Carpinus Americana*, which is used for the cogs of mill-wheels and for agricultural implements. The inner bark dyes yellow.

**Horn (Cape)**, commonly considered the southern extremity of America, is not a part of that continent, but the most southerly point of a small island of the Terra del Fuego group. Lat. 56° 58' 40" S., lon. 67° 16' W. It consists of a lofty, precipitous, bare black rock, running far out into the sea, and was formerly considered dangerous to pass on account of the strong westerly gales that prevail in its neighborhood during summer; but as these are restricted to the vicinity of the Cape, vessels avoid the difficulty by sailing in a higher latitude.

**Horner**, a worker in horn.

**Horn-Lantern**, a lantern having plates or sheets of thin pressed horn in the frame, instead of glass.

**Horn-Lead**, native chloride of lead, so called from its consistence.

**Hornpipe**, an old Welsh musical instrument, consisting of a wooden tube with holes, and a reed and a horn at each end.

**Horn-Quicksilver**, the native bichloride of mercury, or calomel.

**Horns**, a miner's name for the guides for the ropes on the drum.

**Horn-Silver**, native chloride of silver, a transparent, waxy-looking mineral, of a gray, grayish-green, or whitish color. It occurs with native silver in the mines of Mexico, Chili, Peru, Idaho, Nevada, Arizona, etc.

**Hornstone**, a kind of quartz resembling horn, used for forming the grinding-blocks of flint-mills in the pottery manufacture. See CHERT-STONE.

**Horn-Tips**, the solid, pointed tops of horns, which are used for umbrella-tops, knife-handles, and many other purposes.

**Horography**, the art of constructing dials.

**Horologer**, a watchmaker.

**Horology** is the art of making time-measuring instruments. These instruments, and matters relative to them, are treated under ALARM-BELL, BARILLET, CHRONOMETER, CLOCK, ELECTRIC CLOCK, ESCAPEMENT, FUSEE, PENDULUM, SUN-DIAL, WATCH, etc.

**Horometer**, any instrument for measuring the hours, as a clock, a watch, a sun-dial, etc.

**Horometry**, the art of measuring time by hours and subordinate divisions.

**Horse** [Fr. *cheval*; Ger. *Pferd*; It. *cavallo*; Sp. *caballo*], a noble quadruped (*Equus caballus*), whose beauty, strength, and docility have connected him, directly or indirectly, with almost all the purposes of life. The *H.* is strictly herbivorous. His stomach is comparatively small, and he eats often. He sleeps very little, and frequently standing. The foal is used for work when about 3 years old. The *H.* lives for 20 years, but is seldom capable of much work after 15. The age can be ascertained by the teeth till the eighth year, after which it is said to be "past mark." In old animals, however, the gums shrink from the teeth, which are left very long, and become of a yellow or brown color. The *H.* is vastly modified in his form and character by the physical condition of the countries in which he is naturalized. The pony of Norway or of the Highlands of Scotland and the huge *H.* of the plains present extremes of strength and size; while, again, these contrast in a striking manner with the light form and agile shape displayed by those fed on the arid plains and scanty herbage of warmer countries. To the

intermixture of the last with the former the technical term *blood* is applied. Importations of them to England anciently took place from Spain and Barbary, and at a later period from Arabia. The African and Arabian *H.*, accordingly, have given their characters to the blood-horse of England and its innumerable varieties. The animal in which this effect of blood is the most remarkable is the English race-*H.* For the combination of speed with the necessary strength, this creature can scarcely be surpassed. He forms, however, a race of artificial creation, admirably suited for a particular purpose, but not otherwise deserving of cultivation, except from this, that it is the stallions of this race that continue the excellence and purity of the parent stock. The hunter combines the blood of the Arabian and other races of the South and East with the powerful form of the *H.* of the N. of Europe in a much happier proportion than the race-*H.* From the hunter downwards to the races where no mixture of southern blood can be traced the gradations are innumerable. It is in this class that the English road *H.* and hackneys, the horses employed in coaches and carriages of all kinds, are contained. It forms the most numerous class of English *H.* But a large proportion is bad, having lost the hardiness and strength of the native race, without having arrived at the speed and other qualities of good breeding. The remaining class of English *H.* consists of those in which no mixture, or a very slight one, of stranger blood is found. These are the ponies of the highlands, or the larger *H.* of the plains. Of the last, usually termed cart or farm horses, the most commonly enumerated breeds are: (1) The Old English black horse, of very large size, chiefly bred in the midland counties, from Lincolnshire to Staffordshire; (2) the Clydesdale, or breed of the central plains of Scotland; (3) the Cleveland Bay, the origin of the better kind of coach-horse, bred over the whole of Yorkshire and Durham; and (4) the Suffolk Punch, so termed from its punchy form. — The first *H.* brought to America from Europe were imported by Columbus, in his second voyage, in 1493. The first *H.* brought into any part of the territory at present embraced in the U. States were landed at Florida, by Cabeça de Vaca, in 1527, 42 in number, all of which perished or were otherwise killed. The next importation was also brought to Florida, by De Soto, in 1539. The principal breeds of *H.*, adapted for specific purposes, in the Middle, Northern, and Western States, are the Norman, the Canadian, the Morgan, the Conestoga or Pennsylvania, the Virginian, and the Kentuckian. For carriages of heavy draught the Conestogas are regarded by many as the best. For the saddle, draught, and other useful purposes the Morgans are highly prized, especially in New York. For roadsters, the Normans and Canadians are frequently sought. For blood, the Virginians and Kentuckians generally take the lead. Vermont has long been celebrated for its trotting horses, and the *Morgan breed* is so identified with that State, that the name is almost a synonyme for horses raised there. In New York, however, the greatest attention is paid to the business, the single county of Orange having over 100 breeding establishments, some of which are very extensive. Millions of dollars are also invested on stock farms all along the Hudson River in the breeding of trotting horses. There are similar breeding establishments in Iowa and other Western States. For the last 30 to 40 years the value of trotting horses has increased even faster than their number and speed, the rate being at least 100 per cent every decade.

In 1858, Flora Temple was sold for \$8,000; in 1862, the California Danzel for \$11,000, in 1866, Young Pocahontas for \$35,000; and in 1867, Dexter, which in that year surpassed all previous speed, — trotting a mile in 2 minutes 17½ seconds, — sold for \$33,000. It is now no unusual thing for fast-trotting horses and fine stock horses of the best trotting blood to sell for from ten to twenty thousand dollars. This shows the immense popularity of the American breed of trotting horses, and the amount of wealth they represent. The founder of this breed seems to have been Messenger, whose lineage is traceable back to some of the finest Arabian blood in England. He was imported into New York in 1788, and was of superb form and extraordinary power and spirit. His form, with the remarkable vitality and endurance of his race, has endowed his progeny — which has been persistently used and trained to trotting — with extraordinary courage and endurance. So great has been the impress of this wonderful stamina and splendid form upon American horses, that his value to the country may be estimated at millions of dollars. His stock has been bred in-and-in to an unprecedented degree, without any of the disastrous effects generally feared from inbreeding. This success has led many to think that where sire and dam are affected with no disease, inbreeding may be resorted to with safety, the only effect being to intensify in the progeny the characteristics common to both parents. The following table shows the estimated number, average price, and value of the *H.* existing in the U. States on January, 1879: —

STATES.	Number.	Average price.	Value.
Maine.....	81,700	\$62 45	\$5,102,165
New Hampshire.....	57,100	59 69	3,408,299
Vermont.....	75,900	64 82	4,919,838
Massachusetts.....	132,300	57 46	11,570,563
Rhode Island.....	16,200	93 35	1,512,270
Connecticut.....	51,500	75 17	3,871,255
New York.....	890,000	80 77	71,885,300
New Jersey.....	114,500	92 12	10,547,740
Pennsylvania.....	614,500	72 07	44,840,065
Delaware.....	19,900	70 90	1,410,910
Maryland.....	108,600	68 55	7,444,530
Virginia.....	204,600	62 60	12,807,960
North Carolina.....	142,400	67 11	9,550,464
South Carolina.....	57,900	80 72	4,673,688
Georgia.....	118,300	70 77	8,372,091
Florida.....	22,200	70 09	1,555,908
Alabama.....	108,500	58 91	6,391,735
Mississippi.....	95,300	65 62	6,253,586
Louisiana.....	78,600	53 24	4,179,340
Texas.....	725,000	27 45	19,901,250
Arkansas.....	165,200	45 23	7,471,906
Tennessee.....	327,500	52 91	17,228,025
West Virginia.....	117,500	52 32	6,147,600
Kentucky.....	379,300	49 11	18,627,423
Ohio.....	765,000	60 74	46,496,100
Michigan.....	314,900	73 75	23,223,875
Indiana.....	698,800	51 22	34,255,906
Illinois.....	1,091,600	54 84	59,567,800

Colorado.....	50,000	45 00	2,250,000
The Territories.....	90,000	43 17	3,885,300
<b>Total.....</b>	<b>10,829,700</b>		<b>\$600,813,651</b>
<b>General average price.....</b>		<b>\$58.16</b>	

Our export of *H.* (mostly to England) for the year 1878 amounted to 4,104, valued at \$798,723 *Imp. duty*, 20 per cent.

There are few sources of greater annoyance, both to the buyer and the seller of the *H.*, than disputes with regard to soundness. That *H.* is sound in whom there is no disease, nor any alteration of structure in any part which impairs, or is likely to impair, his natural usefulness. That *H.* is unsound that labors under disease, or that has some alteration of structure that does interfere, or is likely to interfere, with his natu-

Fig. 275. — ARABIAN HORSE.

ral usefulness. In the purchase of a *H.*, the buyer usually receives, embodied in the receipt, what is termed a *warranty*. It should be thus expressed:—

“Received of A B \$200 for a gray mare, warranted only five years old, sound, free from vice, and quiet to ride and drive.”

“C. D.”

A receipt including merely the word “warranted,” extends only to soundness,—“warranted sound” extends no further; the age, freedom from vice, and quietness to ride and drive, should be specially named. This warranty extends to every cause of unsoundness that can be detected, or that lurks in the constitution at the time of sale, and to every vicious habit which the animal has hitherto shown. To establish a breach of the warranty, and to be enabled to return the *H.* or recover the price, the purchaser must prove that it was unsound or viciously disposed at the time of sale. In case of cough, the *H.* must have been heard to cough previous to the purchase, or as he was led home, or as soon as he had entered the stables of the purchaser. Coughing, even on the following morning, will not be sufficient; for it is possible that he might have caught cold by change of stabling. No price will imply a warranty, or be equivalent to one; there must be an express warranty. The warranty should be given at the time of sale. A warranty, or a promise to warrant the *H.*, given at any period antecedent to the sale, is invalid. A warranty after the sale is invalid, for it is given without any legal consideration. In order to complete the purchase, there must be a transfer of the animal, or a memorandum of agreement, or the payment of earnest-money; the least sum will suffice for earnest. No verbal promise to buy or to sell is binding without one of these. Where there is no warranty, an action may be brought on the ground of fraud, but this is very difficult to be maintained, and few possibly will hazard it. It will be necessary to prove that the dealer knew the defect, and that the purchaser was imposed upon by his false representation; and that, too, in a case in which a person of ordinary circumspection might have been imposed upon.

**Horse**, a wooden frame for towels or clothes. — A stool or tressel used by many workmen. — The carrying part of a machine, as in tile-making. — A foot-rope to support the feet of seamen while leaning over a yard or boom to furl the sail. — A large round bar of iron fixed in the head of a ship.

**Horse-Barge**, one towed by horses on a canal or narrow river.

**Horse-Bazaar**, a place for the sale of horses.

**Horse-Bean**, a species of *Faba* grown in fields for feeding horses, and of which there are several varieties.

**Horse-Blanket**, a coarse woollen rug with which to clothe horses.

**Horse-Boat**, a ferry-boat for transporting horses across rivers or harbors, etc.

**Horse-Box**, the English term for a closed carriage or vehicle for transporting horses by railway; an enclosure for a horse to be slung into a vessel.

**Horse-Breaker**, one who tames and trains young horses for the saddle or draught.

**Horse-Chestnut**, a very ornamental tree, the *Æsculus hippocastanum*, with an erect trunk, and a pyramidal head, sometimes attaining a height of 90 or 100 feet. The white wood is used for the backs of brushes, and for other ornamental articles. The bark is used in some countries as a febrifuge. The nuts or seeds are large and of a beautiful mahogany color, but exceedingly bitter and unpleasant to the taste. They are of little commercial value. From them, however, starch and vermicelli have been made.

**Horse-Cloth**, a blanket or wrapper for a horse.

**Horse-Collar** a stuffed collar, placed around the neck and against the shoulders of a draught horse to pull by.

**Horse-Comb**, a strong comb used for combing the mane and tail of horses.

**Horse-Dealer**, as defined by Act of Congress, June 30, 1864, “any person whose business it is to buy or sell horses or mules.”

**Horse-Doctor**, a farrier; a veterinary surgeon.

**Horse-Drench**, a drastic purge for a horse; also the horn by which the medicine is administered.

**Horse-Dung**, the droppings from horses, in stables, etc., collected for manure.

**Horse-Fair**, a market for the sale of horses.

**Horse-Fettler**, a workman in mines who provides for and attends to the horses kept underground.

**Horse-Flesh**, a name for a species of Bahamas mahogany. — The carcass of horses sold to the knackers.

**Horse-Grease**, the melted fat obtained by boiling the carcasses of horses. It is exported from South America under the name of mare’s grease.

**Horse-Hair**, the long hair of the mane and tail of the horse, which is valuable for many trade purposes. See **HAIR**.

**Horse-Hide**, the skin of the horse, which, when tanned, makes the strong cordovan leather, and is also used for covering large board-room or office tables.

**Horse-Hoe**, the English name for a **HOEING-MACHINE**.

**Horse-Knacker**, a purchaser of diseased or worn-out horses, who kills them for their commercial products.

**Horse-Load**, the weight which a horse can draw, which is about 2500 lbs.

**Horse-Mill**, a mill worked by a horse.

**Horse-Power**, a unit of force introduced by Watt to enable him to determine what size of engine to send to his customers to supersede the number of horses which the new power was to replace. Watt accepted the result of certain experiments which seemed to show that the average force exerted by the strongest horse was sufficient to raise 33,000 lbs. one foot high in a minute; thus, an engine of 200 *H.-P.* would be a force equal to that of 200 horses, each lifting 33,000 lbs. one foot high per minute. Watt had two methods of estimating and comparing his engines, viz., by the power, and by the duty. By the power is meant the quantity of work which an engine can effect in a given time; by the duty is meant the quantity of work which it can effect by a given expenditure of fuel. Now, it is evident that without any change in the size of an engine, but simply by increasing the pressure of the steam, the power of an engine may be greatly increased,—that is, the load remaining constant, the speed of the piston may be increased, the number of strokes may be increased, and, con-

sequently, the work done per minute will be increased also. Hence it is difficult to apply a limit to the power obtainable from the smallest cylinder, provided the boiler be large enough to evaporate the increased quantity of water, and strong enough to resist the increased bursting pressure. In fact, no size of cylinder can be reckoned as having a particular power, since the power depends not on size but on strength. Nevertheless, in modern engineering the term *horse-power* refers rather to the size of the cylinder than to the power exerted, and the value of the unit has undergone many changes; so that in a modern engine, a *H.P.* may imply 52,000 lbs., or 60,000 lbs., or 66,000 lbs., one foot high per minute. The plan now adopted for ascertaining the performances of different engines is by an instrument called an *indicator*. This consists of a small cylinder fitted with a piston, which is pressed down by a spring. By the height to which this piston rises against the spring the steam pressure within the cylinder of the engine is indicated; and the number of pounds pressure on the square inch multiplied into the number of square inches in the area of the cylinder, and by the number of feet travelled through by the piston per minute, gives the efficient moving power, which, divided by 33,000, gives the actual *H.P.* From the above it results that by improved arrangements in every part a cylinder of a certain capacity will do more work than Watt had assigned to it. Hence a certain *H.P. nominal* now only denotes a certain capacity of cylinder; whereas the *effective* or *real* power denotes the actual working efficiency. Most engineers now believe that Watt's figures, 33,000 lbs., are too high for a real *H.P.*; but the *foot-pound* (see *HEAT, MECHANICAL EQUIVALENT OF*) is still based upon them for the sake of uniformity in statements and tabulations. In the great ocean steamers now built, the nominal and the real *H.P.* of the engines are both frequently named; and it is observable that they diverge more and more from equality.

*Horse-power* is also the name given to machines in which the power of horses is used to drive other machinery. Fig. 276 shows a four-horse-power machine having two gears and shafts, so that two different rates of motion may be taken from it. A connection with the *first* shaft gives its tumbling-rod about 10½ revolutions to one round of the horses, or about 30 revolutions per minute. The tumbling-rod, when set on the *second* shaft, gets about 25 revolutions to one round of the horses, or about 75 per minute, and would give the hand wheel of jack about 300. This power is adapted to general use on farms, working feed-mills, pumps, saws, etc.

Table showing the estimated Power of Man or Horse as applied to Machinery.

Application of the Power.	Lbs. avr. at the rate of 220 feet per minute.	Lbs. avr. at the rate of one foot per minute.
A man is supposed to be capable of lifting or carrying .....	27.273	6,000
A man is supposed to be capable of turning the winch of a crane with a force equal to .....	28.637	6,300
When the united efforts of two men are applied to the winch of a crane, the handles being at right angles, each man exerts a force equal to .....	33.499	7,350
A man is supposed to exert a power in pumping equal to .....	17.335	3,814
In rigging, a man exerts a force equal to .....	38.955	8,570
And in rowing .....	40.955	9,010
The power of a horse is equal to...	150	33,000

**Horse-Radish**, the pungent root of the *Cochlearia armoracia*, used as a condiment, on account of its pungent, acrid, and stimulant qualities.

**Horse-Railroad**, a city or suburban railroad, whose cars are drawn by horses.

**Horse-Repository**, a place where horses are kept on sale and view, or put up at auction periodically.

**Horse-Run**, a contrivance in deep earthworks

Fig. 276. — DOUBLE-GEARED HORSE-POWER MACHINE

for drawing up and lowering a man with a wheelbarrow.

**Horseshoe**, a semicircular plate of iron nailed to the hoofs of horses to protect the frog or sole of the foot. They are manufactured by machinery on a large scale at Troy, New York. They are forwarded in casks, and sold by the ton or cwt.

**Horseshoe Nail**, a nail with flat pointed tang and heavy counter-sunk head, made of tough iron, and used to fasten horseshoes to hoofs of horses. Their usual lengths are as follows:—

No. 5.....1½ inches	No. 8.....2 inches
No. 6.....1¾ "	No. 9.....2½ "
No. 7.....1¾ "	No. 10.....2½ "

**Horse-Tail**. See *DUTCH RUSH*.

**Horse-Trappings**, the saddlery and harness for a horse.

**Horsewhip**, a light whip for horsemen; those for ladies are often very elegantly mounted.

**Horticulture, Gardening**, the art of cultivating gardens. It differs from agriculture chiefly in the comparatively limited space over which it extends, and in being conducted by manual labor; whilst the latter is performed jointly by human and animal labor, in fields, or on an extensive tract of land called a farm.

**Hose**, socks, stockings, or coverings for the legs. — Flexible tubing used for the conveyance of water, more usually made of a fabric covered with leather, or coated with india-rubber or gutta-percha.

**Hose-Cart**, a reel mounted on wheels to carry hose for fire-engine service.

**Hoshens, Hoeshens** [Scotch], stockings without feet.

**Hosier**, one who manufactures or sells articles of hosiery.

**Hosiery**. The word *hose* meant *long stockings*, in regard to the garments of past ages; and on that ground the terms hosiery and stockings became applied indiscriminately. But *H.*, in a manufacturing sense, now means something more than stockings. It is a comprehensive designation for those textile fabrics — for whatever kinds of garment intended — which are made by a sort of *knitting*, or chain-work, unlike the regular long threads and cross-threads of ordinary weaving; and therefore gloves, drawers, under-waistcoats, nightcaps, shawls, etc., are included, as well as stockings, under the name of *H.* The counties of Leicester,

Nottingham, and Derby are the chief seats of this manufacture in England; in the first, woollen *H* is the principal branch; in the second, cotton; and in the third, silk. Woollen hose are also made on a considerable scale in Wales, and at Hawick, in Scotland. The principal seat of the German cotton *H*, is Chemnitz, in Saxony. *Imp.* duty according to material. See **KNITTING**.

**Hospital**, an infirmary; a public institution for the reception of sick persons. By the laws of the U. States foreign seamen arriving in the U. States pay each 20 cents per month to the collector of the port, as hospital money, and pay 25 cents per day when in hospitals under medical treatment.

Fig. 277. — HOT-BLAST SMELTING-FURNACE.

Marine hospitals are erected by the U. States at New York, New Orleans, Boston, and other ports, for the accommodation of disabled and sick seamen, under the supervision of the Treasury Department. For disabled naval officers and seamen, navy hospitals have been erected at Philadelphia, Brooklyn, N. Y., Norfolk, and other seaports, supported by grants by Congress, and from contributions of one ration per day from each inmate.

**Hot-Bed**, a forcing-pit containing horse-dung and other manure, and covered with glass for raising early plants.

**Hot-Blast**. The air driven into an iron-smelting furnace by the blowing-machine or cold-blast

has a tendency, in the first instance, to cool the contents of the furnace by its cold current; and this suggested the probability that it would be worth while to make the air hot *before* admitting it to the furnace. This idea has led to the establishment of one of the greatest improvements in the iron manufacture, — the *hot-blast*. Not only is more fuel saved in the furnace than is used in the preliminary warming of the air, but the contents of the furnace can be raised to a higher temperature, thus permitting the fusion of certain kinds of ore which would be infusible by the cold-blast. But there is more than this. Not only are fuel,

lime, and time economized, and otherwise refractory ores brought into use; but coal can be used in addition to, or instead of, coke, with a consequent saving of part of the expense involved in coking. These numerous advantages have brought the hot-blast into a high degree of favor. The air is heated in a kind of stove provided with a series of cast-iron pipes over a fire-place; the air is made to pass through the tubes (which are 6 or 8 inches in diameter, and arranged like vertical siphons) into two horizontal tubes of larger diameter, and thence into a large cylinder. From this cylinder the air is drawn into the cylinder of the blowing-machine, whence it is forced into the blast-furnace (Fig. 277). In most blast-furnaces each tuyère, or nozzle, is provided with its own air-heating apparatus; and from 30 to 35 tons of coal per week will heat to 600° F. sufficient air to make 60 tons of pig-iron. A very scientific mode is sometimes adopted of utilizing the waste heat of the blast-furnace by making it heat the air of the hot-blast. The amount of heat thrown out at the chimney of most of our great furnaces, in the forms of flame and smoke, is something enormous; amounting, it is computed, to 60 or 80 per cent of the whole heat generated in the furnace. Many plans have been proposed, and some of them tried, for saving this valuable but wasted heat for the purpose here named. One of these plans depends upon the construction of peculiar stoves nearly on a level with the top of the furnace. Hot air, from the throat of the furnace, passes through flues into a chamber containing tubes filled with the cold air for the blast; this cold air, being thus heated to 600° F., or more, passes down pipes to the blowing-machine, and thence into the furnace. The hot air of the furnace is not the same air as that of the blast; the former heats the tubes in which the latter is contained. This is rendered possible, because the heat at the throat of the furnace is tremendous, as much as 1800° F. The scientific theory of this mode of hot-blast is complete; the only doubt is in the efficacy of the practical application. Some kinds of iron, nevertheless, are of better quality when smelted by the cold-blast. See **IRON**.

**Hotel**, a house for lodging and entertaining travellers. In France, the term is also applied to a private house or large urban mansion.

**Hôtel-de-Ville**, the city hall of a French town.

**Hot-Flue**, an apartment heated by stoves or steam-pipes, where goods are dried.

**Hot-House**, a building constructed in a garden, or elsewhere, and warmed by artificial means, for the purpose of rearing exotics and other tender

plants, which require more heat than our climate affords.

**Hot-pressed Paper**, paper of which the sheets have been smoothed and glazed by passing them between heated rollers of polished steel.

**Hot-Short**, a term applied to iron which cannot be easily welded, and has a tendency to crack or break when it is worked at a red heat.

**Hot-water Heating Apparatus**, a system of pipes for conveying steam or hot water for warming churches and other public institutions, dwellings, horticultural buildings, etc.

**Hot-water Plate**, a deep, metal-covered plate, filled with boiling water, to keep victuals warm.

**Houguette**, the etching-needle of the marble-worker.

**Houille**, the French name for pit coal.

**Hounds**, projections at the mast-head of a ship, on which the tops or trestle trees rest. — Side bars applied to certain portions of the running-gears of a carriage to give them strength.

**Houppelande** [Fr.], a riding-coat.

**Hour**, a division of time; the 24th part of the day.

**Hour-Glass**. See SAND-GLASS.

**Hour-Hand**, the short index-hand of a clock or watch; that which points to the hour, while the long hand indicates the minutes.

**Housatonic R.R.** runs from Bridgeport, Conn., to State line, Mass., 74 m., and operates under lease the following lines: The Berkshire R.R., from Conn. State line to West Stockbridge, Mass., 22 m.; the West Stockbridge R.R., from West Stockbridge to New York State line, 2.75 m.; the Stockbridge and Pittsfield R. R., from Vandeuensville to Pittsfield, Mass., 22 m.; and the New York, Housatonic, and Northern R. R., from Brookfield Junction to Danbury, Conn., 5.50 m., making a total of 126.25 m. of road operated. This Co., whose offices are in Bridgeport, Conn., was chartered in 1836; the road was opened in 1842. *Financial statement:* Cap. stock, common, \$820,000; preferred 8%, \$1,180,000; funded debt, 1st mortgage 7% bonds, issued 1865, \$100,000, payable 1885; 2d mortgage 6% bonds, issued 1869, \$300,000, payable 1889.

**House**, a place of residence; a building of various forms, styles, and dimensions, occupied by dwellings. — A sea term, implying to protect or secure anything, as housing a gun, mast, etc. — A term for a business firm; a commercial establishment; a mercantile or business concern; as, the house of Taylor and Taylor.

**House-Agent**, a person intrusted with the letting of houses or apartments, estates, etc.

**House-Breaking**, entering a house for unlawful purposes in the daytime; a felonious entry at night is termed burglary.

**House-Decorator**, one who combines the business of several trades, painting, paper-hanging, whitewashing, etc.

**House-Dog**, a terrier, mastiff, or some other dog kept chained up for the protection of a dwelling.

**House-Factor**, an agent in Scotland for the sale or letting of houses.

**House-Flag**, the distinguishing flag of a particular owner or firm, generally carried on the main-mast of the ship.

**House-furnishing Goods**, a general trade name for a countless variety of household articles, such as brooms, brushes, cooking utensils, cutlery, hollow-ware, iron and wooden wares, etc.

**Householder**, the occupier and renter of a house.

**Households**, a technical name among English millers for the best flour made from red wheat, with a small portion of white wheat mixed.

**House-Joiner**, a carpenter who does work for the interior of houses.

**House-Keeper**, the head woman-servant or manager of a household; one who has the charge of the ménage.

**Housemaid**, an indoor domestic, one who attends table, and has the care of the furniture, rooms, etc.

**Housewife**, a kind of needle-book, or case, for holding thread, needles, buttons, etc., often taken to sea by sailors.

**Housing**, a covering or protection to anything, as to a vessel laid up in harbor or dock. — A small cord used at sea, made of three small yarns, and used for seizings; also termed house-line.

**Houston and Texas Central R.R.** runs from Houston to Red River City, Texas, 345 m.; with branches from Hempstead to Austin, 118.75 m., and from Bremond to Ross, 58 m., making a total of 521.75 m. owned. This Co., whose offices are in Houston, was chartered in 1848 and the road opened in 1873. It has a land-grant of 16 sections from the State of Texas for every mile of road built and equipped. *Financial statement:* Cap. stock, \$7,722,000; funded debt, \$14,586,500; school-fund loan (State of Texas), \$315,494.86. The lands granted amount to 5,240,000 acres, estimated value \$1 per acre. Funded debt in detail: 1st mortgage main line bonds, issued 1866, \$6,262,000, payable 1891, interest 7% (June and July); 1st mortgage bonds, western division, issued 1870, \$2,270,000, payable 1891, interest 7% (June and July); 1st mortgage bonds, Waco and North Western, issued 1873, \$969,000, payable 1903, interest 7% (June and July); consolidated mortgage, issued 1872, \$3,642,000, payable 1902, interest 8% (August and Oct.); consolidated mortgage, W. & N. W., issued 1875, \$84,000, payable 1915, interest 8% (May and Nov.); income and indemnity bonds, issued 1877, \$1,359,500, payable 1917, interest 7% (May and Nov.). The school-fund loan bears 6% interest with a sinking-fund of 2%, and is secured by \$570,000 bonds reserved by the trustees.

**Howard**, a fire-insurance Co. located in New York City, organized in 1825. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$500,000; net surplus, \$133,943.07. Risks in force, \$23,844,854; premiums, \$201,075.77. Premiums received since March, 1836, \$6,416,894; losses paid since March, 1836, \$4,314,819; cash dividends paid to stockholders, \$2,005,875.

**Howdah**, the body of an Indian carriage; a small pavilion or car, with trappings, on the back of an elephant.

**Howdy**, in Scotland, a midwife.

**Howitzer**, a kind of gun, from which large shot and shell may be thrown at short ranges. These guns are constructed in brass and iron. Brass *H.* form part of a field-battery, and are used for firing shell to clear a village, or any similar position that it is necessary to occupy. They vary in length from 2 feet to 4 feet 9 inches, and will throw 4½ inch and 5½ inch shells. Iron *H.*, from 4 to 5 feet in length, which throw 8-inch and 10-inch shells, are used in sieges, especially for ricochet firing. *H.* are longer than mortars, and shorter than guns of the same calibre; they require a small charge of powder, but the angle of elevation at which they are fired is high.

**Howker**, a two-masted Dutch vessel; a kind

of hulk; also a small fishing-smack, used on the Irish coasts.

**Hoy**, a small passenger sloop employed on the sea-coast, or in conveying cargo from a ship in a roadstead or bay.

**H. P.**, the abbreviation for "horse-power" and "half-pay."

**Hub**, a fluted screw of hardened steel, adapted to be placed on a mandrel between the centres of a lathe, notched to present cutting edges, and to be used in cutting screw-tools, chasing-tools, etc. — In die-sinking, a cylindrical piece of steel on which the design for a coin is engraved in relief. *E. H. Knight.* — In carriage-making, a nave.

**Huanaco Bark.** See CINCHONA.

**Hubble-Bubble**, the bottom of a hookah, or snake-pipe.

**Hubla**, a weight for pearls and diamonds, used in Sindh; about 2 grains troy.

**Huckaback**, a species of very coarse diaper, made of flax, used for towelling, table linen, etc.

**Huckster**, an inferior dealer or minor trader; a hawk or itinerant vender of goods with a pack, box, or tray.

**Hudson**, a river of the State of New York, and one of the most important in the United States. It rises in the Adirondack mountains by two branches which, after a separate course of about 40 m., unite in Warren County. After a S. course of 15 m. the H. receives the Sacandaga, on the line between Montgomery and Saratoga Counties. It then runs for 15 m. S. E. to Hadley Falls, and for 20 m. N. E. to Glen's Falls. Its direction is then nearly S. to its entrance in New York Bay. It receives from the W., 40 m. below Glen's Falls, and 170 m. from its mouth, its greatest tributary, the Mohawk. The length of the H., from its entrance into New York Bay, is a little over 300 m. So straight is this river between Albany and New York, that the distance is less by water than by land. The tide flows to a little above Albany. It is navigable for the largest ships 118 m., to Hudson, and for sloops and large steamboats, 145 m. above New York, to Albany. Small sloops also proceed to Troy, and through the dam and lock to Waterford, about 8 m. further. Through a considerable part of its course the banks are elevated, and in some parts high, rocky, and precipitous; particularly in its passage through the Highlands, 63 miles above the city of New York. The scenery on the banks of the Hudson is highly picturesque. The city of New York owes much of its prosperity, and its pre-eminent advantages, to this noble river, which is unrivalled as a navigable medium of commerce. It is connected by the Erie Canal with the Great Lakes, by the Champlain Canal with the St. Lawrence River, and by the Delaware and Hudson Canal with the Delaware River and the Pennsylvania coal region. By no other route can an equally favorable water communication be had with the great West. There are many large and flourishing towns on the H. The principal on the east side are Troy, Hudson, Poughkeepsie, Peekskill, Sing Sing, Tarrytown, Yonkers, and New York; and on the west side, Waterford, West Troy, Albany, Catskill, Kingston, Rondout, Newburgh, Haverstraw, Nyack, Piermont, Hoboken, and Jersey City. The largest tributaries of the H., beside the Mohawk, are the Hoosac, Walkil, and Croton. Spuyten Duyvil creek connects it with the Harlem River, which flows into the East River, forming the N. boundary of Manhattan Island.

**Hué.** See COCHIN CHINA.

**Huffing**, a process of ornamenting gilded leather.

**Huile**, the French name for oil.

**Huissier**, an usher or door-keeper in a French court; a public officer, a process-server, whose duty it is to draw up and deliver, at the residence of parties concerned, official legal documents, etc.

**Huitre**, the French name for oyster.

**Hujaum**, an East Indian barber.

**Hulk**, the hull of an old vessel, employed in harbors for various purposes.

**Hull**, the body of a ship, exclusive of the masts, rigging, etc. *Hull down* expresses that the hull of the ship is concealed by the convexity of the sea.

**Hull.** See GREAT BRITAIN (Seaports).

**Hulling**, the process of cleaning grass-seeds and cereal grains.

**Human Hair.** See HAIR.

**Hummeler**, an instrument for clearing barley of the haws or awels.

**Humming-Top**, a hollow spinning-top. — A child's toy.

**Humulin**, the name given to a beautiful extract or essence of hops, made as follows: —

A concentrated tincture of hops is prepared by percolation with rectified spirit; the same hops are then exhausted with water; the spirit is removed from the tincture by careful distillation, and the upper aqueous portion is skimmed off, and added to the infusion, which latter is then evaporated to the consistence of a soft extract; the oleo-resinous residuum of the tincture is next added, and well mixed in; after which the whole is put into pots and carefully tied over for sale. The product possesses all the fragrant, tonic, and bitter qualities of the hop in a highly condensed form. See HOP.

**Hundred**, in numeration, twice fifty; but in commerce, a variable amount of different goods. Though in Great Britain, as in America, the legal hundred-weight be 112 lbs., the English hundred for sugar is 108 lbs.; for wool, 110 lbs.; for iron, 120 lbs. In Maryland, the hundred is 100 lbs. In Belgium, the hundred of articles sold at market is invariably 104 pieces. The hundred of planks or deals in Sweden is 120, in Westwyck 124, in Christiana 127, and in some other northern European ports, 132 (see GREAT HUNDRED). — A division or part of a county in England and in the State of Delaware.

**Hundred-Weight**, the chief measure of weight for bulky articles, containing 112 lbs. avoirdupois; the 20th part of a ton. It is generally written, for shortness' sake, *cwt.* (See CWT.)

**Hungary.** See AUSTRIA-HUNGARY.

**Hungary-Water**, **Queen of Hungary's Water**, an old-fashioned but delicious perfume for the toilet, distilled with water and spirits of wine from the tops of rosemary flowers.

**Hungary Wines** have long enjoyed a well-merited fame. The varieties of these wines which are capable of being rendered fit for exportation are few, but these few rank so high in the highest class of the products of the vintage, that they have borne the name of Hungarian Wine far beyond where it has ever been tasted or seen. The vineyards which produce the best wines are those of Ofen, Pesth, Tokay, the Syrmia in the South, Groswarden, Erlon, and Warwitz in the Bannat. The consumption in the country is very considerable, amounting to about 350,000,000 gallons, while the exports scarcely reach 35,000,000 gallons.

The manufacture of the wine is very coarsely carried on by the peasantry, who are, notwithstanding their want of care and system, very observant of cleanliness in all that concerns the vintage. The wine-presses and vats are well cleaned with boiling water in which vine leaves have been steeped. The fruit is collected in wooden vessels, which are carried by the laborers, and overseer attend to see that no grapes are left on the vines. The different gatherings are collected in vats having a double

bottom, the uppermost of which is pierced with holes for the juice to pass through, while the grapes are beaten and bruised with a stick. When the upper vessel is full, its contents are taken to the press. They generally divide the gathering for the red and white wines, but do not reject the bad grapes. All are pressed together, and the must thrown into a large vat to ferment. When the grapes are too abundant for the operation of pressing, they put them into sacks and tread them out, and the contents of the sack are afterwards put by for distillation. About 30 kinds of *H. W.* have been reckoned. The most celebrated is the *Tokay*, the product of a district around the town of that name, extending about 20 m., called the Submontine or Hegyalla, in High Hungary. The grapes for this wine, which are large, and of a rich, luscious taste, are the Hungarian Blue, when ripe called *Trockenbeeren*. They are collected late in the season when already almost shrivelled up to raisins, and are carefully picked one and one. The species called *Formint* and *Hais-Seciu* furnish the prime *Tokay*, called *Tokay Ausbruch*. The *Trockenbeeren* are over-ripe in October, and are carefully placed on a grooved table, from which the juice runs into earthen jars, and forms the rich "essence of *Tokay*," from their own pressure. This wine is like the sirups of the South of France, and is set aside by itself. The quantity made is small and very thick, and is considered most precious. The grapes are then trodden in a vat with the naked feet, and a small portion of wine essence is added to the must, which is allowed to stand 24 hours, and then set to ferment. This last is the famous *Tokay* wine, or *Tokay Ausbruch* (*ausbruch*, or flowing forth of the sirup). It ferments for two or three days or more, during which it is stirred, and the matters which arise to the surface are skimmed off. It is then strained into casks. *Tokay* has a powerful aroma. It does not become bright for some time after it is in the cask. *Tokay Ausbruch* contains 61 parts of essence and 84 of wine. The *Maslas* is a more diluted species of the *Tokay*, containing 61 parts of essence and 169 of wine. The best wine of *Tokay* has so peculiar a flavor of the aromatic kind, and is so luscious, that the taste is not easily forgotten. This wine sells in Vienna for about \$4 the small *Tokay* bottle, and much dearer when 40 or 50 years old. The vineyard belongs to the Emperor and certain of the nobles; that called *Taizal* produces the best. The side of the slope on which the vineyards lie is about 9,000 yards long; but the choice portion, called *Mezes-Male*, is but 600, and is reserved with its produce for the Emperor and a few of the nobles. *Tokay* and *Mada* come next. The vineyard of *Tallya* is reputed to have most body, and that of *Zambor* the greatest strength. The wines from *Szeghi* and *Tsadyan* are the most aromatic, while the wines of *Tolesva* and *Erdo Benye* are best for exportation. *Tokay* cannot be drank under three years old. The wine ferments in the casks on transportation by sea, and thus clarifies itself. In bottling, a space must be left between the cork and the wine, or the bottle will break. In Hungary a little oil is poured upon the wine, it is then corked, and a piece of bladder tied firmly over the cork. At *Craeau* this wine has been kept of the hundredth vintage. The new is called there *vino stiki*; the old, *vino virauno*. The color of the prime *Tokay* should not be of a reddish hue, though there is an inferior sort of that color; the taste soft, and not sharp or acrimonious, it should appear oily in the glass, and have an astringent twang, a little earthy. The aroma, however, cannot be mistaken, as that of no other wine resembles it. The wine of *Buda* is red, and was once a favorite in England. The *Szard* resembles *Bordeaux*, and the *Groswarden* wine is of excellent body. The red *Meneser* wine is very good, and with *Menes-Tokay* is grown upon a range of hills of clay slate, so called from the village of *Menes*. The *Tokay* essence is enormously dear, and even in Vienna is rarely to be tasted at the tables of the opulent. The practice of mingling the essence with the common wines has given the latter a celebrity which they scarcely deserve, and lessened the quantity of the essence sold. These wines have a harsh taste, which is highly esteemed in some parts of the Continent. The genuine *Tokay* is commonly exported in wood, but frequently in bottle. The bottles do not contain more than a pint and a quarter. The value of *Tokay* is another example of the caprice of taste or fashion in wine. The rich muscadine of *Syracuse* or the *lagnina* of *Malaga* seem in every respect equal to it in richness; though the peculiar flavor in the wine of *Tokay* will easily distinguish it from them, yet that flavor itself has nothing more than its singularity to recommend it. Few Americans would prefer *Tokay* to wines very much its inferior in fame, did they dare to contradict the decision of fashion in its favor. The vine is also largely cultivated in Austria, the average yield being estimated at about 300,000,000 gallons, including some very good wines, and many more of a very poor quality. In Austria Proper the best are grown in the neighborhood of *Liechtenstein*. They are stronger than Rhine wines, are of a greenish hue, and may be drank young. The best wine next to the Hungarian is made in *Transylvania*. An *Ausbruch*, resembling *Tokay*, is grown there; and some very good wines are made near *Birthalmen*. In the *Pyrol* and vicinity of *Trent* much common wine is made of excellent quality; but it is all consumed in the country. In *Carynthia* wines resembling those of Italy are produced, particularly near *Moetting* and *Wipach*. The *Luttenberg* wines of *Lower Styria* are among the first in

Germany: those of *Sansal* and *Wiesel* are much extolled. In *Istria* good wine is also made. *Piasecco*, *Antignana*, *St. Serf*, and *Trieste* produce red, white, and *mousseux* wines, well flavored. *Berchitz* is a wine grown on a rock in the *Adriatic*, sweet, and of a deep red color. *Vins de liqueur* are made at *Capo d'Istria*, *Pirano*, and *Citta Nova*, called *St. Ipatronio Piccoli*, *Petit Tokai*, and *St. Thomas* are very excellent wines of their class. *Syrnia* and *Posega*, in *Slavonia*, produce red and white wines of good flavor and strength. The neighborhood of *Carlowitz* is noted for its red wine. The wines of *Croatia* are made best at *Mosyina*, and resemble *Burgundy*. In *Dalmatia* they make a wine at *Sibenico*, called *Maraschina*, whence the name of the liqueur *Maraschino* di *Zara* in the same territory. In *Moldavia* the best reputed vineyards are near *Cotnar*. The wine of that name is green, and becomes deeper by age. It is nearly as spirituous as brandy, and by many is preferred to *Tokay*.

**Hunter**, a pursuer of wild animals for sport or sustenance; also a strong heavy horse suited for the chase.

**Hunting-Boots**, long boots with white tops.

**Hunting-Coat**, a scarlet or green coat, or some particular costume worn by a company of hunters.

**Hunting-Cog**, in machinery, one more cog in the larger of two geared-wheels than would be required to establish an exact relative ratio between the number of cogs in this wheel and that in the smaller.

**Hunting-Horn**, a bugle; a horn used to cheer the hounds in pursuit of game.—Also, a musical wind-instrument of a circular form, made of metal, and belonging to the horn series. See *Horn*.

**Hurdle**, a movable wooden frame of split timber or wattled osiers.—Also an iron fence for protecting trees, enclosing land, or folding cattle and sheep.

**Hurds**, the refuse of flax; any waste tow or oakum.

**Hurdy-Gurdy**, a stringed musical instrument, whose sounds are produced by the friction of a wheel and regulated by the fingers. It is only suited to simple music, and was used for such as had many repetitions. Its simplicity and cheapness rendered it, at one time, a favorite instrument among the peasantry of Europe. The instrument is now mostly to be seen in the hands of Savoyard boys, who play it on the streets.

**Huron (Lake)**, one of the five great lakes of N. America, lies between Lake Superior on the N. W., Lake Michigan on the W., and Lake Erie and Lake Ontario on the S. and S. E. Its shape is so irregular that it is difficult accurately to determine its exact dimensions. Its length from N. to S. is 260 m., and 160 m. in breadth from E. to W., in its widest part, but exclusive of the bay on the N. E., it is only 90, and its circumference 1,100 m. Its principal indentations are *Saginaw Bay*, extending into Michigan, and two others; one immediately N. of *Manitou Islands*, and the other S. E. of them. The latter, called *Georgian Bay*, is about 170 m. long by 70 broad,—almost a separate sheet of water, divided from *H.* by a nearly continuous series of islands which are closely connected by the great peninsula of *Cabot's Head*, and with *Point de Tour*, the easternmost cape of northern Michigan. *Manitou Island* is the largest of the group, and *Drummond Island* separates another sheet of water from the main lake, 80 m. long and 20 broad. The boundary between the U. States and Canada passes along the middle of the main *Huron* 225 miles, and between *Lesser Manitou* and *Drummond Islands*, by what is called the *Middle Passage*, and curves round to the N. and W. 25 m., to the entrance of *St. Mary's River*. The elevation of the surface of Lake *H.* above the surface of the ocean is 574 feet, or less than that of Lake Superior by 53 feet, or than that of Lake Michigan by 4 feet. Lake *H.* receives no river worthy of

mention. Its banks are mostly low, especially along its S. and W. sides. Few towns of consequence exist on its shores, and its navigation is rendered dangerous by sudden and violent tempests. Its greatest depth toward its W. shore is at least 1,000 feet, and its mean depth 900 feet, or about 300 feet below the level of the Atlantic.

**Hurries**, timber stages having spouts by which coals are shot into vessels.

**Hurse-Skin**, a name for the hard, tuberculated skin of a fish, from which shagreen is made, to cover lancet-cases, pocket-books, sword-hilts, etc.

**Hurricane**, a violent storm, generally accompanied with thunder and lightning, and distinguished from every other kind of tempest by the vehemence of the wind and the sudden changes to which it is subject. *H.* prevail chiefly in the East and West Indies, Mauritius, and in some parts of China.

**Husbandage**, the agent or managing owner's allowance or commission for attending to a ship's business.

**Husbandman**, an agriculturist; a farmer.

**Husk**, the shell, or external covering of certain fruits or seeds of plants; the rind; the bark; especially the ears of Indian corn.

**Hussy, Huswife**. Same as HOUSEWIFE.

**Hutch**, a box or cistern. — A cage for tame rabbits. — A basket in which coals are brought from the mines. — A measure of two bushels; six hutches of coal make a cartload of about 14 cwt.

**Hyacinth**, a bulbous plant, genus *Hyacinthus*. There are numerous and very beautiful varieties cultivated in gardens. The bulbs are largely imported from Holland, and are often grown in water contained in suitable glass vessels (hyacinth glasses). — The term is also applied to crystallized varieties of zircon, a valuable gem of various shades of red, passing into orange and poppy red.

**Hydragogues** are medicines which cause the removal of water from any of the cavities of the body. Many cathartics, as gamboge, jalap, etc., are classed under this head.

**Hyalotype**, a photographic positive on glass.

**Hydrant**, a water-plug; a pipe or spout for discharging water at a fire.

**Hydra-Pult**, a force-pump on a portable scale.

**Hydrate**, a chemical combination of water with other substances, as hydrate of chloral.

**Hydraulic Cement, Water-Lime**, the name given to a class of cements which have the power of hardening under water. See CEMENT.

**Hydraulic Engineering**, that branch of engineering which treats of the appliance of water as a motive-power for mechanical purposes, and the methods that must be adopted to offer an effective resistance to the pressure which is exercised by any great volume of that fluid, whether it be in a state of rest or in motion.

**Hydraulic Motor**, a water-engine.

**Hydraulic Press**. See HYDROSTATIC PRESS.

**Hydraulic Ram**, a kind of force-pump originally invented by Montgolfier, for raising small quantities of water, by employing its own momentum, to heights considerably above the source of supply.

**Hydraulic Wheel**. See WATER-WHEEL.

**Hydrocarbon**, a compound of carbon and hydrogen. The hydrocarbons constitute a most important series of organic compounds.

**Hydrochloric Acid** is a colorless gas, very acid to the taste and irritating to the eyes; it induces coughing even if breathed in small quantities, or when largely diluted, and is very destructive to vegetation. It has a sp. gr. of 1.261.

When subjected to a pressure of 40 atmospheres at 50° F., it becomes a colorless fluid capable of dissolving bitumen, and having a sp. gr. of 1.27. It has never been frozen. *H. A.* neither burns nor supports combustion. The white fumes which it forms when exposed to the air are due to its condensing the atmospheric moisture, and thus giving rise to a body less volatile than water. This gas is greedily and instantly absorbed by water. A fragment of ice placed in a jar of the gas absorbs it, and becomes immediately dissolved. Commercial *H. A.* is usually of a yellow color, owing to its being contaminated with iron. It also very frequently contains sodium, arsenic, sulphuric and sulphurous acids, and free chlorine. Pure aqueous solution of *H. A.* should leave no residue upon evaporation; it should give no precipitation of ferric oxide when saturated with ammonia; sulphuretted hydrogen should cause no turbidity in it; if diluted with three or four times its volume of water, and chloride of barium be added, no white cloud or precipitate should form in the mixture; nor should the acid, if pure, discolor a fluid made faintly blue with iodide of starch. *H. A.* is largely consumed in the manufacture of chlorine, sal ammoniac, chloride antimony, glue, phosphorus, in the preparation of carbonic acid for the manufacture of artificial mineral waters, in beet-root sugar-works, hydrometallurgy, and alone, or mixed with nitric acid, for dissolving various metals.

**Hydrocyanic Acid, Prussic Acid**, a colorless liquid, having a sp. gr. of 0.7058 at 44.6° F. It is very inflammable, burning with a violet flame resembling that of cyanogen, but somewhat whiter in color. It is soluble in all proportions in water, the resulting mixture being lighter than that fluid, and miscible with alcohol. It is very feebly acid; potassic cyanide always having an alkaline reaction. Red oxide of mercury is readily dissolved by it, and when added to a solution of argentic nitrate it precipitates white flocculi of cyanide of silver. Anhydrous *H. A.* is an extremely volatile liquid; if a drop be let fall on a glass plate, part of it becomes frozen by the cold produced by its own evaporation. It is found in water distilled from kernels of the apricot, the peach, the plum, the cherry, the leaves of the laurel, and some other shrubs. The kernels of the bitter almond also yield it by distillation, mixed with an essential oil. The juice of the tapioca plant likewise contains it. Many nitrogenous substances, when submitted to destructive distillation, also evolve *H. A.* The observance of the greatest care and caution are necessary in the preparation and handling of this most potent poison.

**Hydro Extractor**, the name given to a machine acted by centrifugal force, and used for wringing and drying clothes.

**Hydrogen**, a most important elementary body discovered by Cavendish in 1766. Combined with oxygen it constitutes water, and in this form is extensively distributed through earth, air, and ocean. It is an important constituent of all organized tissues. It is always obtained for experimental purposes by the deoxidation of water. *H.* is gaseous, colorless, tasteless, odorless (when pure), combustible. Sp. gr. .06935, being 16 times lighter than oxygen gas, and 14.4 times lighter than atmospheric air. 100 cubic inches, at 60° F. and 30 inches of the barometer, weigh 2.1371 (say 2.14) gr.; 1 gr. occupies 46.6 inches. It is very readily inflamed, even by a red-hot wire. It burns with a scarcely visible flame. Mixed with atmospheric air or oxygen, it explodes with extreme violence

on the approach of flame, or sudden compression. One measure of *H.* and 5 of atmospheric air, and 2 of *H.* and 1 of oxygen, are the proportions that explode with the greatest violence. The combination of *H.* and oxygen, when mixed, is brought about by the heat of a red-hot solid or a flame, by the electric spark, and by the presence of spongy platinum, the black powder of platinum, clean platinum foil, and some other substances. A jet of *H.* burnt in oxygen gas, or a jet of these gases (mixed) burnt in the air, with proper precautions, produces a most intense heat. *H.* has recently been liquefied and even solidified. It is recognized by its combustibility, the pale color of its flame, producing water only when burnt in air or oxygen, extinguishing the flame of other bodies, and exploding when mixed with half its volume of oxygen, and fired. — Pure and uncombined *H.* is not employed in the arts. Inhalations of this gas have, however, been occasionally used in medicine. In combination, the uses of *H.* are almost numberless. Combined with oxygen, it forms water; with chlorine, hydrochloric acid; with fluorine, hydrofluoric acid; with cyanogen, hydrocyanic acid; with carbon, innumerable hydrocarbons; with nitrogen, ammonia; with sulphur, sulphuretted hydrogen, — in fact, an enumeration of the valuable compounds which it enters into would occupy many pages of this work. From its extreme lightness it has been used to fill balloons, but coal-gas is now commonly employed for this purpose. The chemist avails himself of the great heat developed by its combustion in oxygen in the formation of the *oxyhydrogen blowpipe*.

**Carburetted *H.*** This term is specially applied to two of the numerous compounds of carbon and *H.*: 1. *Light carburetted H.*, *Fire-Damp*, or *Marsh-Gas*, is a colorless, neutral, nearly inodorous gas. It burns with a yellow flame, producing pure water and carbonic acid. It explodes when kindled in contact with air or oxygen. (See *FIRE-DAMP*.) 2. *Heavy carburetted H.* (See *OVERMANT GAS*). — *Coal Gas*, *Oil Gas*, and *Resin Gas*, consist, for the most part, of mixtures of these two gaseous hydrocarbons in uncertain proportions, respectively from coal, oil, and resin, by the action of heat, and are used for the purposes of illumination. See *GAS*.

**Peroxide of *H.*** *Oxygenated Water*, is a colorless, transparent, somewhat sirupy liquid, of sp. gr. 1.452. It has a metallic taste, and corrodes the skin. It is easily resolved into oxygen and water. It mixes freely with water, and becomes more permanent by the dilution. It bleaches organic substances, and acts as a powerful oxidizing agent. Under certain circumstances, however, it plays the part of a reducing agent. Peroxide of hydrogen has been applied in the arts to restore the blackened lights of paintings which have become darkened by sulphuretted *H.*; it is also sold by hair-dressers for bleaching human hair.

**Hydrographical Charts or Maps**, usually called sea-charts, are projections of some part of the sea or coast for the use of navigation. In these are laid down all the rhumbs, or points of the compass, the meridians, parallels, etc., with the coasts, capes, islands, rocks, shoals, shallows, etc., in their proper places and proportions.

**Hydrography**, the art of measuring and describing the sea, rivers, canals, lakes, and the like. With regard to the sea, it gives an account of its tides, counter-tides, soundings, bays, gulfs, creeks, and also of the rocks, shelves, sands, shallows, promontories, and harbors; the distance and bearing of one port from another, with everything that is remarkable, whether out at sea or on the coast.

**Hydromel**, an aqueous solution of honey; a refreshing and slightly laxative drink.

**Hydrometer, Areometer**, an instrument for ascertaining the specific gravities of liquids, and hence their strength, the latter being either in inverse or direct proportion to the former. *H.* are of two kinds: 1st, those which are always immersed to the same depth in distilled water and

the liquid to be tried, small weights being used for the purpose, as in Fahrenheit's and Nicholson's *H.*; 2d, those which are suffered to rise or sink freely in the liquid, until they come to a state of rest, as in Baumé's, Syke's, etc. In both cases a correction must be made for any variation in temperature. Of the two kinds, the first give the most accurate results, and have the great advantage of being applicable to liquids either lighter or heavier than water, but the second are the readier in practice, requiring less time and less skill to use them. The following are those best known: —

**Baumé's *H.***, which is generally employed on the Continent of Europe and recognized in the U. States, consists of two distinct instruments, the one for liquids heavier than water, the other for liquids lighter than that fluid. The first floats at the 0, or "zero," of the scale in distilled water, at the temperature of 58° F., and each degree, marked downwards, indicates a density corresponding to 1 per cent of common salt. The *H.* for liquids lighter than water is poised so that the 0 of the scale is at the bottom of the stem when it is floating in a solution of 1 oz. of common salt in 9 oz. of water, and the depth to which it sinks in distilled water shows 10°; the space between these fixed points being equally divided, and the graduation continued upwards to the top of the scale. The temperature at which these instruments were originally adjusted by Baumé was 12.5° Centigrade (54.5° F.). They are now commonly adjusted in England at 58° or 60° F. Hence arise the discrepancies frequently observable in the published tables of the "correspondence between degrees of Baumé and real specific gravities."

**Cartier's *H.***, which is much used in France for light liquids, has the same point for the zero of its scale as Baumé's, but its degrees are rather smaller, 30° Baumé being equal to 32° Cartier.

**Fahrenheit's *H.*** (Fig. 278) consists of a hollow ball, with a counterpoise below, and a very slender stem above, terminating in a small dish. The middle or half-length of the stem is distinguished by a fine line across it. In this instrument every division of the stem is rejected, and it is immersed in all experiments to the middle of the stem by placing proper weights in the little dish above. Then, as the part immersed is constantly of the same magnitude, and the whole weight of the *H.* is known, this last weight, added to the weights in the dish, will be equal to the weight of fluid displaced by the instrument; and, accordingly, the specific gravities for the common form of the tables will be had by the proportion: As the whole weight of the hydrometer and its load, when adjusted in distilled water, is to the number 1000, so is the whole weight when adjusted in any other fluid, to the number expressing its specific gravity.

**Gay-Lussac's alcoholometer** is used to determine the strength of spirituous liquors. It at once indicates on the stem the percentage of absolute alcohol in the liquid examined. The original experiments of Gay-Lussac having been made on liquids at a temperature of 59° F., all examples examined by the alcoholometer must either be brought to that temperature previous to being tested, or a correction made in the strength found.

**Nicholson's *H.*** is constructed on the same principle as Fahrenheit's. It has in addition to the small dish for weights above, a little cup attached below, for holding any solid body whose weight in water is required. It is chiefly intended for taking the sp. gr. of minerals.

**Richter's *H.*** resembles, for the most part, Gay-Lussac's.

**Syke's *H.*** consists of a thin, flat stem, about six inches in length, divided on both sides into eleven equal parts, each of which is again subdivided into two. This stem carries a hollow brass ball, about one inch and a half in diameter, in which is fixed a conical stalk terminating in a pear-shaped weight, so that when the instrument is placed in a fluid, it may float with the other extremity perpendicular to the surface. Ten different weights of different magnitudes are also applicable to the lower portion of the graduated stem. Nine of these weights are circular, with a slit in each to fit the stem, and are numbered respectively 10, 20, 30, 40, 50, 60, 70, 80, and 90. By the successive application of these the instrument may be sunk so as to obtain the whole range of specific gravities, from pure alcohol to distilled water. The tenth weight is in the form of a parallelopiped, and can be fixed, when necessary, to the upper part of the stem. In order to calculate the strength

FIG. 278 — FAHRENHEIT'S  
HYDROMETER.

of a portion of spirit by this *H.*, a portion of the liquid is placed in a tall glass vessel, and the temperature noted by means of the thermometer. The instrument is then floated, and one or more of the weights is added, until the lower part of the scale sinks beneath the surface. The number on the stem in contact with the surface is then observed, and added to the number of the circular weight employed; and this third number is referred to a series of tables calculated for the purpose, and usually sold with the instrument. In these tables, under the proper temperature, will be found the percentage of strength required.

*Tralle's H.* resembles Gay-Lussac's (nearly).

*Twaddell's H.* is much used in bleaching establishments. According to this scale, 0 is equal to 1000 or the sp. gr. of distilled water, and each degree is equal to .005; so that, by multiplying this number by the number of degrees marked on the scale, and adding 1, the real sp. gr. is obtained.

*Alcoholometers, saccharometers, urinometers, etc.*, are simply *H.* so weighted and graduated as to adapt them for testing spirits, sirups, urine, etc.

**Hydrometrograph**, an instrument for measuring the quantity of water discharged in a given time.

**Hydrophore**, an instrument for obtaining specimens of water from any given depth below the surface.

**Hydroscope**, a hygrometer.

**Hydrostat**, a general term for any apparatus or contrivance to prevent the explosion of steam-boilers.

**Hydrostatic Balance**, a balance for weighing substances in water, for the purpose of ascertaining their specific gravity.

**Hydrostatic Press, Hydraulic Press**, also called *Bramah's Press*, from the name of the engineer who first devised it under its actual form, is a heavy iron machine worked by water-power, and very advantageously used in many branches of industry.

The *H. P.*, of which there are many different forms, adapted to different uses, is constructed on this principle: that if a close

vessel is filled with a liquid that we will suppose to have no weight, and if an aperture of the size of one square inch be made in one side of it and fitted with a piston upon which there is exerted a pressure of 10 lbs., there will also be exerted

Fig. 280. — REGNAULT'S HYGROMETER.

will receive a pressure of 1,000 lbs. In the model shown in Fig. 279, P is a reservoir of water on which is a pump, A, the piston-rod, *a*, of which is worked by the hand-lever, O. The water is conveyed by the pipe, *d*, to the cylinder, R, to the piston, C, and table, K, which rises between the guides that hold the upper plate, M N, against which the object under pressure is driven. The force developed is hardly conceivable, frequently testing the strength of the mechanism in a severe way.

The power of a *H. P.* depends mainly on the ratio between the diameter of the pump-piston and that of the cylinder-plunger. The largest of these machines ever known were those constructed for raising the Britannia Tubular Bridge at the Menai Straits. One of them had a plunger or ram 20 inches diameter, and the metal of the cylinder 11 inches thick; a 40-horse-power steam-engine was used to work it, and the head of the ram had a lifting power of 900 tons. In the every-day processes of manufacture, the *H. P.* is largely used in oil mills, cloth dressing and packing establishments, bandana print-works, and numerous other mills and manufacturing establishments.

**Hygrometer**, an instrument for measuring the amount of moisture in the atmosphere.

Regnault's *H.*, shown in Fig. 280, consists of two thin, polished, silver thimbles, two inches in height and one inch in diameter. In these thimbles are adjusted two glass tubes, D and E, each containing a very sensitive thermometer fixed there with a cork. A tube open on both sides goes through the cork of tube D to the bottom of the thimble. This tube, D, communicates through a lead pipe with an aspirator, G, filled with water. The tube E does not communicate with the aspirator; it contains only a thermometer whose object is to

Fig. 279. — HYDROSTATIC PRESS.

vessel is filled with a liquid that we will suppose to have no weight, and if an aperture of the size of one square inch be made in one side of it and fitted with a piston upon which there is exerted a pressure of 10 lbs., there will also be exerted

with an aspirator, G, filled with water. The tube E does not communicate with the aspirator; it contains only a thermometer whose object is to

show the temperature of the air at the time of the experiment. This *H.* is worked by filling about half of the tube, D, with ether, and then opening the cock of the aspirator. The water which fills the aspirator empties itself, which causes a partial vacuum in the tube, A. Air is then forced into the tube, A, by atmospheric pressure; but as that air, to penetrate in the tube, D, and in the aspirator, has to pass through the ether, it vaporizes a part of that liquid, and cools it with a rapidity corresponding to that with which the aspirator discharges its water. The cooling soon determines

on the thimble a deposit of dew, and the thermometer, T, giving them the corresponding temperature, it becomes easy to calculate the hygrometric condition of the air.

**Hypsometer**, an instrument for measuring heights by noting differences in barometric pressures at different altitudes.

**Hyson**, an esteemed kind of green tea, of which there are several varieties, as hyson-skin, young hyson, etc.

**Hysterometer**, a surgical knife for operations upon the womb.

## I

**I**, in Roman numeration, stands for one. When placed before another numeral it is subtracted from, and when following is added to, the value of the other numeral; as IX, 9; XI, 11.

**Ibis**, a genus of birds resembling the storks; the plumage of several is used for ornamental purposes.

**Ice** is water in a solid state. On being cooled, water gradually contracts until the temperature has fallen to  $39^{\circ} 9'$  F., when it begins to expand. At the freezing-point,  $32^{\circ}$  F., under ordinary conditions, water crystallizes or freezes, and in consequence of the continued expansion, the sp. gr. of ice, as compared with that of water at  $39^{\circ} 9'$ , is as .94 to 1.00. Ice has the peculiar property of reuniting by the contact of adjoining surfaces after having been broken into fragments; which property is called *regelation*. Colored water and salt water, by freezing, produce colorless and fresh ice, and spirituous liquors part with their alcohol. To effect this purification perfectly, the ice must be formed under circumstances which prevent the accumulation of blebs and air-bubbles, and the entanglement in the ice of any of the unfrozen or ejected liquor; for the foreign matters held previously in solution in the water are in the act of freezing transferred to the portion which remains unfrozen. If the whole of the water becomes a mass of porous ice, the impurities are retained in the pores; but if the freezing takes place slowly and regularly, time is given for the escape of the impurities, and thus the brilliant and perfectly transparent and dense masses of ice which come from the most northern countries yield, when thawed, water almost equal in purity to that which has been distilled, and nearly free from air.

The ice-trade of the U. States was commenced by Mr. Frederic Tudor, of Boston, in 1805. This gentleman, having previously sent agents to the West Indies to procure information, determined to make his first experiment in that region. Finding no one willing to receive so strange an article on shipboard, he was compelled to purchase a vessel, the brig *Favorite*, of about 130 tons, which he loaded with ice from a pond in Saugus, Mass., belonging to his father, and sent to St. Pierre, Martinique. This first enterprise resulted in a loss of about \$4,500, but was, nevertheless, followed up until the embargo and war put an end to the foreign trade, at which period it had yielded no profit to its projector. Its operations had been confined to Martinique and Jamaica. After the close of the war in 1814, Mr. Tudor recommenced his operations. He obtained the monopoly of the Havana supply in 1815; introduced the trade in Charleston, S. C., in 1817; in Charleston in 1818; in New Orleans in 1820; sent the first cargo of ice to the East Indies in 1833; and to Brazil in 1834. Up to that time Mr. Tudor was alone in the trade, but it was soon divided among many parties in the same and other ports. From the Great Lakes also ice is now carried by railroad to the Southern cities, and through the Illinois River ice is sent down the Mississippi. The shipments of ice in Boston have steadily decreased from 145,000 tons in 1856 to 53,180 tons in 1878. Boston, however, still retains the great bulk of the export trade. The total exports from the U. States for the year 1878 were 64,370 tons (of which 48,215 tons for Boston), valued at \$227,828, and distributed as follows:—

Brazil.....	1,600
Danish W. Indies.....	3,219
French.....	2,802
Canada.....	625
British W. Indies.....	10,822
"    Guiana.....	3,164
"    E. Indies.....	13,270
Hawaiian Islands.....	559
Dutch E. Indies.....	3,175
Cuba.....	16,081
Porto Rico.....	752

Uruguay.....	2,994
Venezuela.....	307
Total.....	64,370

New York exports but little ice, being chiefly engaged in procuring an amount sufficient for its enormous supply, which, including Brooklyn, amounts to about 1,000,000 tons, and is increasing at the rate of about 60,000 tons a year. New York city is chiefly supplied with ice from the Hudson River, above Newburgh, and from the small neighboring lakes. The Knickerbocker Ice Co., which engrosses a large proportion of the business, derives its supply from Rockland and Highland lakes. Ice being shipped and used at all seasons, large store-houses are required to preserve it. These store-houses are huge wooden buildings without windows, standing along the edge of the ponds or along the banks of the rivers. Their capacity frequently exceeds 20,000 tons, and two at Rockland Lake, N. Y., hold 40,000 tons each. At first the implements of husbandry only were used in securing ice, but as the trade became more important, other machines and different methods were adopted, and abandoned when better were brought forward, or when the increased magnitude of the business required greater facilities. More ice is now secured in one favorable day than would have supplied the whole trade thirty years ago. Ordinarily, before there has been cold enough to form ice of suitable thickness, snow falls on its surface. If this occurs when the ice is four or more inches in thickness, and the snow not heavy enough to sink the ice, it can be removed by using horses attached to the *snow-scraper*; and under such circumstances this is the method in common use. But if snow falls so heavy as to bring the water above the surface of the ice, it is removed, after it has congealed into snow-ice, with the *ice-plane*, which takes off about two inches deep and 22 inches wide of its surface. This machine is drawn by two horses, and is guided by inserting its "guides" into grooves previously made with the *ice-cutter*. The chips made by it are scraped off in the same manner as dry snow. These preliminary expenses are often very great; frequently, after much expense has been incurred to remove a body of snow or snow-ice, the weather becomes warm and spoils the ice on which so much has been expended. And, on the other hand, if it is not done and the cold continues, there will be little or no increase of thickness to the ice, which is equally a disaster. When ice has been formed of sufficient thickness, and freed from snow and snow-ice, it is reduced to blocks of uniform size, ordinarily 22 inches square, by the *ice-cutter*. This machine is similar to a carpenter's plough, except that it has a series of cutting chisels, one succeeding another, and deepening the groove. It is drawn by a horse, and cuts at one passage about two inches deep, and if the ice requires to be planed to remove snow-ice, the guides of the "snow-plane" are used in grooves of this depth, but when grooves are required to split from, the "ice-cutter" should be drawn two or three times through each. These grooves should be parallel to each other, and to make them so, the "ice-cutter" has a guide, which is placed in the last groove made. When the grooves in one direction have been made, others at right angles with them are produced in the same manner. After this has been done, one groove at the end is opened, and also the two outside grooves: a wedging-bar is then stricken into the groove next the end one, and at several places along its length, which detaches it easily from the mass; then the same bar is forced, with a slight blow, into the transverse grooves, which reduces the ice to very uniform square blocks. The blocks of ice thus formed are brought to the receiving-doors of the ice-houses (which are built on the immediate borders of the ponds), either by placing them on sleds, or floating in canals cut through the ice. Various modes of elevating the ice are in use; the endless chain, in combination with the inclined plane, has been successfully used, and also the common pile-driving steam-engine; but at present horsepower is more used than any other. The ice is placed in the houses in regular courses, every block exactly covering the next below it. When a vault has been filled, it is immediately covered with wood-shavings and the receiving-doors fitted up, to prevent waste, until the contents are required for shipment abroad or use at home. The weight of ice for shipment is usually determined at the wharves, immediately before being put on shipboard, on scales which have been constructed for the purpose; and this single operation settles the weight to be paid for by the party for whose account the ice is shipped; the amount due for freight on shipboard, for transportation on the railroad, and that which is to be received by the owner of the ice. The artificial freezing of water is principally effected by vaporization and expansion, and by liquefaction. The method by liquefaction is performed by freezing mixtures, many of which will bring water into the state of ice even in the hottest weather. The most important freezing mixtures are given in the following table:—

Substances.	Parts by Weight.	Thermometer sinks		Degrees of fall.
		from	to	
Snow or powdered ice....	2	-10	-56	46
Common salt.....	1			
Snow.....	8			
Dilute sulphuric acid....	3	+50	0°	50
" nitric acid.....	3			
Sulphate of soda.....	8			
Hydrochloric acid.....	5	+50	-14	64
Sulphate of soda.....	6			
Nitrate of ammonia.....	5			
Dilute nitric acid.....	4	+50	-21	71
Phosphate of soda.....	9			
Nitrate of ammonia.....	6			
Dilute nitric acid.....	4	+32	-51	83
Snow or powdered ice....	3			
Potash.....	4			

Numerous *ice-machines* have been invented to facilitate the action of these mixtures upon water, or produce ice by vaporization. Among the best known are those invented by Masters, Harrison, Siebe, Carré, Kirk, Windhausen, Holden, Giffard, etc. It does not enter into the scope of this work to describe one or other of these machines, which are generally complicated and expensive; and it is enough to say that in every case there is some chemical agent which takes away caloric, or heat, from a vessel of water and thereby converts the water into ice. The usefulness of ice-machines seems to be limited to exceptional cases in a country as the U. States, which possesses every facility for the production and shipping of natural ice, and cheap transportation by railroads and rivers in almost every part of the country. Thirty years ago the hotels and other large consumers in New York paid \$20 per ton for their ice. Now, owing to the introduction of machinery, the better understanding of the business, and the competition between rival companies, the price is reduced to four or five dollars to persons who consume large quantities of ice. The rate to families is not considered much above this price, when the waste of cutting into small pieces and cost of carting are taken into account.

**Ice-Boat**, a boat so constructed as to sail upon ice. Ice-boats are very common in Holland; they go with incredible swiftness, sometimes so quickly as to affect the breath, and are found very useful in conveying goods and passengers across lakes and great rivers. Boats of different sizes are placed in a traverse form upon a 2½ or 3 inch deal board. At the extremity of each end are fixed irons, which turn up in the form of skates. Upon this plank the boat rests, and the two ends serve as outriggers to prevent oversetting, whence ropes are fastened that lead to the head of the mast in the nature of shrouds, and others passed through a block across the bowsprit. The rudder is made somewhat like a hatchet with the head placed downward, which being pressed down cuts the ice, and serves all the purposes of a rudder in the water, by enabling the helmsman to steer.

**Ice-Box, Ice-Chest.** See REFRIGERATOR.

**Ice-Bound**, vessels blocked up in the ice.

**Ice-Claw**, a rope and pair of claws, for grappling ice-blocks.

**Ice-Cream Freezer.** See FREEZER.

**Ice-Crusher**, an implement for crushing ice for cooling beverages.

**Iceland.** See DENMARK.

**Iceland-Moss**, a lichen (*Cetraria Islandica*) common in the N. of Europe and N. America, which yields a nutritive starchy substance, sometimes employed to make bread and gruel. It may be formed into a paste; and from its possessing demulcent qualities, as well as a bitter principle, it is extensively employed in consumption and other diseases, being regarded as a dietetic as well as therapeutic agent. *Imp. free.*

**Iceland-Spar**, calcareous spar in transparent crystals, first brought from Iceland. It is much

employed in optical experiments, and is sometimes called double-refracting spar.

**Ice-Plane**, an instrument for smoothing away the rough surface of ice in winter, before cutting and carting it away for storage.

**Ice-Plough**, an instrument used for cutting grooves in the ice on ponds and lakes, to facilitate the removal of blocks of 1 to 2 cwt., which are stored for summer use.

**Ice-Safe**, a chamber for cooling water, etc.

**Ice-Saw**, a long saw, with a heavy weight, attached at the lower end (Fig. 281), for cutting channels in the ice to liberate vessels which have been frozen in.

**Ice-Tongs**, utensils for taking up ice at a table.

**Icea Resin**, resinous exudations of value in the districts of S. America, where the *Icea* trees occur, and furnish the elemi, carana, and tacamahaca resins.

Fig. 281. — ICE-SAW.

**Idaho**, a N. Western territory of the U. States, bounded N. by British Columbia, E. by Montana and Wyoming, S. by Utah and Nevada, and W. by Oregon and Washington. It lies between lat. 42° and 49° N., lon. 111° and 167° 10' W. Extreme length from N. to S., 485 m.; greatest breadth, about 290 m. Area, 86,294 sq. m., or 55,228,160 acres. Pop. about 25,000, exclusive of tribal Indians, who in 1880 numbered about 5,500. The principal towns, each with a very small pop., are Boise City (the capital), Lewiston, Oregon, Idaho City, Malade City, Pioneer City, and Silver City.

The Snake River, or Lewis Fork of the Columbia River, and its branches drain the entire territory, except a portion about 120 m. long in the extreme N., which is watered by Clark's Fork, the Spokane, and the Kootenay, and a small tract in the S. E. corner, which is intersected by Bear River. Clark's Fork crosses the territory from E. to W., expanding into a lake about 30 m. long and 5 m. wide, near the E. boundary, called Pend d'Oreille. The river and lake are navigable by steamers through Idaho. The surface of Idaho possesses characteristics similar to those of the great inland basin lying further S., being elevated, within the Sierra Nevada and Cascade Mountains on the W., and the Bitter Root and Rocky Mountains on the E., to an altitude of from 2,000 to 5,000 feet above the sea, and having insufficient rainfall for the highest development of vegetation during the summer months without the aid of irrigation. The tendency to aridity, however, is considerably less than in Utah and Nevada, the average range of summer heat in this northern latitude not being so exhaustive of the surface moisture. The many streams intersecting the valleys, having their sources in mountain heights covered with snow during the greater part of the year, also offer unsurpassed advantages for irrigation, and render this one of the most copiously watered of our inland territories. The necessity for irrigation is much less apparent in the N. portion of the territory than further S.; but the extreme cold which often attends the winters of the latitudes approaching the British boundary repels the immigrant agriculturist, and this region consequently contains fewer settlements than the central and southern parts. The mountains of Idaho often attain great altitude, having peaks rising above the line of perpetual snow, their lower slopes being furrowed with numerous streams and alternately clothed with magnificent forests and rich grasses. The plains are elevated table-lands covered with indigenous grasses, constituting pasturage unsurpassed in any section of our country. Among the largest, best situated, and most attractive of the valleys are those of the Clearwater, Salmon, Fayette, Wood, Welter, St Joseph, and Coeur d'Alene, these being all profusely watered, and possessing soil of extraordinary fertility, readily yielding, with irrigation, abundant crops of barley, wheat, rye, and oats, as well as all the ordinary vegetables and fruits of the temperate zone; while vast stretches of magnificent forest, presenting abundant supplies of timber and firewood, constitute a conspicuous element of beautiful mountain scenery. Bottom-lands of great fertility and considerable extent surround the shores of lakes Coeur d'Alene and Pend d'Oreilles, in the N. part of the Territory; and there are numerous small

but very productive valleys on the streams emptying into those lakes. The preference of agricultural settlers, however, is for the valleys lying within the water-system of the more S. branch of the Columbia. Throughout the spring, summer, and autumn months, in the N. as well as the S. sections, the weather is generally delightful and salubrious; in the winter months the range of the thermometer depends greatly upon the altitude of the surface, the higher mountains being visited by extreme cold, and heavy falls of snow; the lower mountain ranges and the plains having winters generally less severe than those of N. Iowa and Wisconsin or central Minnesota, while greater dryness of the atmosphere renders a lower fall of the thermometer less perceptible; and the valleys being rarely visited by cold weather, high winds, or considerable falls of snow. Considered in its yearly average, the climate is exactly adapted to sheep-growing and the production of wool; the herding of cattle, and the manufacture of dairy products; the raising of very superior breeds of horses, as well as the culture of all northern varieties of fruits, such as apples, pears, plums, cherries, peaches, grapes, and all of the ordinary cereals and vegetables. Besides the great wealth in mines of gold and silver which Idaho contains, constituting the principal attraction to emigrants thus far in the history of the Territory, extensive deposits of not less important useful minerals are known to exist in different sections within its limits, although there has yet been no organized geological survey. Conspicuous among the useful minerals are vast beds of salt, found upon analysis to be almost chemically pure, extensive fields of iron ore, and apparently inexhaustible strata of excellent coal. The coal and salt are already prominent among the mining products; the local demand created by their employment in the process of reducing and refining the ores of gold and silver, as well as by domestic necessity, rendering their production profitable; but increased facilities for transportation to adjacent States and Territories are required to develop these branches of mining industry to a degree commensurate with the great extent and value of the deposits. The first discoveries of gold in paying quantities in Idaho were made in 1890, on the south Fork of Clearwater River. The principal quartz-mines are in the S. W. part, in Owyhee, Idaho, Boise, and Alturas Counties. Placer diggings occur in various parts of the Territory; the most important are those of Boise basin and along the head-waters of the Salmon and Clearwater rivers. Until 1869 the annual yield of gold and silver ranged from 6 to 8 millions of dollars. Since that time it has been yearly decreasing, the yield for the year 1878 being only \$1,150,000 gold, and \$200,000 silver. There is a national bank at Boise City, with a capital of \$100,000. No railroads have yet been constructed in Idaho, but as the line of the Union and Central Pacific roads runs in close proximity to its S. boundary, it receives a generous share of the benefits conferred upon this section of the country by the great national inter-oceanic highway. According to the estimate of the commissioner of the U. States general land office, the total area of Idaho is approximately estimated to contain of agricultural lands 16,925,000 acres; grazing, 5,000,000; surface of lakes, 575,000; sterile lands, producing no other vegetation than wild sage and occasional tufts of buffalo-grass, 14,328,130; mountain lands, 18,400,000 — embracing 17,500,000 acres of timber lands, and 8,000,000 of mineral lands.

**Illegal**, any act contrary to law, such as the use of false weights and measures, smuggling, etc.  
**Illicit**, unlawful, prohibited; as secret distillation, etc.

**Illinois**, a Western State of the American Union, bounded N. by Wisconsin, N. E. by Lake

Fig. 232. — SEAL OF ILLINOIS.

Michigan, E. by Indiana, S. E. and S. by Kentucky, and W. by Missouri and Iowa. It lies between lat. 36° 39' and 42° 30' N., lon. 87° 35' and 91° 40' W. Its extreme length from N. to S. is 385 m., extreme breadth from E. to W. 218 m. Area, 55,410 sq. m. This important State is divided into 102 counties. Chicago, its commercial metropolis, is the largest city of the West. The seat of government, Springfield, is a fine city, lying near the geographical centre of the State, in lat. 39° 48' N., lon. 89° 45' W.; it has an active trade and important manufactures, with a population of about

30,000. The other principal cities of Illinois are: Alton, pop. 10,000; Aurora, 15,000; Belleville, 10,000; Bloomington, 18,000; Cairo, 7,500; Decatur, 8,000; Elgin, 7,000; Freeport, 9,000; Galena, 9,000; Galesburg, 12,000; Jacksonville, 11,000; Joliet, 9,000; La Salle, 6,000; Ottawa, 9,000; Pekin, 6,500; Peoria, 28,000; Quincy, 40,000; Rockford, 14,000; Rock Island, 9,000. Total population of Illinois, about 3,000,000.

Illinois may be regarded as an extensive table-land, gently inclining toward the S. W. At the mouth of the Ohio the soil is only about 340 feet above tide-water in the Gulf of Mexico, and the highest elevation in the whole State does not exceed 800 feet above that standard. Its surface is occupied almost entirely by prairies, which are popularly distinguished by the names, "wet" and "dry," "alluvial" and "rolling." The wet prairies are peaty, indicating that they were once morasses. Those of an alluvial nature are dry, with a rich black loam, and exceedingly fertile. They are covered with a coarse kind of grass, which grows to an enormous size. The soil of the high and "rolling" prairies is, in general, only of second-rate quality, and abounds in springs. Grape-vines are abundant. The prairies furnish an inexhaustible summer range for cattle. From the exceeding flatness of some of the plains, the rains that fall are allowed to stagnate, and thus render the situation unhealthy. The Grand Prairie, which is the largest tract of this description, is probably the highest table-land between the Mississippi and the Wabash. It extends from the county of Jackson, in a N. E. direction, to the Iroquois county, and varies in breadth from 1 to upward of 12 m. Although passing under one name, it does not consist of one single tract of land, but is broken up into several reaches of prairie ground, with strips of wood running between them. It is rich and fertile, and several settlements have been located on its border, which is everywhere skirted with wood. The prairies, generally, are not plentifully supplied with timber, most of them being only interspersed with groups of trees, or skirted with strips of forest. Much of the young wood is destroyed by the annual winter burning of the coarse grass, which covers at least two thirds of the prairie land. In spring the prairies again become profusely decked with the greatest variety of beautiful and delicate flowers of every hue. Illinois is distant from the sea, but is well provided with rivers. Nearly three fourths of its boundary is formed by navigable rivers; and on the N. E. it has Lake Michigan for upward of 60 m. The Mississippi, which forms its entire western, and the Ohio, which forms the southern boundary, give commercial access to those valleys which bear their names. The Wabash, a noble stream which bounds the State on the E. for more than 100 m., is navigable for more than that distance. For internal communication, the Illinois, which belongs entirely to this State, is navigable at all seasons for steamboats for 260 m. to La Salle, where navigation is stopped occasionally by the little rapids, and where a canal branches off, connecting the river with Lake Michigan. The principal tributaries of the Illinois, which is itself formed by the junction of the Kankakee and the Des Plaines, are the Fox River which rises in Huron Territory, and has a course of 200 m. before it joins the Illinois; the Vermilion River, which falls into it from the S. E.; the Sangamon from the E., the Mackinaw from the N. E., and the Spoon River from the N. W. These are almost all navigable for considerable distances. The Sangamon is navigable for 140 m. The Little Wabash and the Embarrass, which flow into the Wabash, are likewise navigable for upwards of 150 m. The Rock River, which rises in Wisconsin, and falls into the Mississippi, after a course of about 300 m., is navigable for some distance, but its upper course is impeded by rapids. The climate of Illinois, extending as it does over a space of 54 degrees of latitude, must necessarily be varied. The natural difference of temperature between the N. and the S. parts is, however, increased by the numerous and large rivers which bound and intersect the country, and by its state of cultivation. Everywhere the winters are severe, the summers hot and long, and the temperature subject to frequent and sudden changes. In the S. parts of the State the summer heat is very oppressive and enervating; and is only occasionally relieved by fresh breezes from the prairies. In winter the snow falls to a considerable depth, and lies occasionally for three months; and many of the rivers remain frozen for the same length of time. In some parts of the State only a few inches of snow falls, and it quickly disappears. — Illinois possesses a vast extent of arable land. The soil, although varied, is generally highly productive, and for agriculture, it has been considered as unsurpassed by any State in the American Union. The soil in "the bottoms," or along the river valleys, such as those of the Rock River, the Sangamon, and Kaskaskia, consists chiefly of rich alluvial deposits, and is so productive as frequently to yield 40 bushels of wheat or 100 bushels of Indian corn to the acre. Nearly all the tracts adjacent to the rivers are of this character. "The American Bottom," as it is called, is the richest river alluvium, and has been cropped without deterioration for a century. It extends along the Mississippi for 90 m.; but in consequence of its illa-

bility to inundation, much of it is uncultivated. The prairies, although less productive, are still very fertile, and on account of their greater salubrity are preferred for farms, wherever wood is to be obtained. In 1879 there were 25,882,861 acres of land in farms, and 6,019,531 acres in woodland (of which 5,961,578 acres were included in farms) — Important and valuable minerals abound in this State. Bituminous coal occurs in almost every county, and in some instances may be obtained without excavation. Vast beds are found on the bluffs adjacent to the "American Bottom"; and it has been reported that anthracite coal has been found in the county of Jackson. But the great coal region is an extensive tract which extends quite across the State from Missouri to Indiana, and from Iowa to Kentucky (see COAL). Iron has been found in the S. part of the State, and is said to be plentiful in the N. The great lead region is shared between Illinois, Iowa, and Wisconsin. Galena, in the N. W., is nearly supported by this mineral. Silver has also been found in the W. part of the State, and copper is obtained in several places. The other minerals found here are zinc, gypsum, quartz, crystals, etc. — The relative value of agricultural products of I. for the year 1878 is given in this work under the names of each of the principal crops. In that year there were about 200 butter and cheese factories in operation in the State, and the value of the annual product of the factories and milk-condensing establishments was over \$2,000,000; and all the dairy products of the State were more than double this estimate. — According to the last census, Illinois ranked sixth among the States of the Union in the amount of capital invested in manufactures and in the value of products. In the total amount of capital it was surpassed by New York, Pennsylvania, Massachusetts, Ohio, and Connecticut: in the value of products by New York, Pennsylvania, Massachusetts, Ohio, and Missouri. In the production of agricultural implements, Illinois ranked next to Ohio and New York; in carriages and wagons, next to New York and Pennsylvania; in sashes, doors, and blinds, next to New York, Pennsylvania, Missouri, and Ohio; in men's clothing, next to New York, Pennsylvania, Massachusetts, and Ohio; in oil, next to New York and Pennsylvania; in grease and tallow, next to New York; while in the products of butchering, distilled liquors, platted lumber, and pork packed, it ranked first. Illinois also ranks first among all States in the number of miles of railroad it possesses. The following table exhibits the names of the lines lying wholly or partly within the State, the number of miles completed in 1879, and the entire length of the lines.

In 1879 Illinois had 139 national banks in operation, whose paid-in capital was \$17,194,600. There were, besides, 319 State banks, savings-banks, and private bankers, whose capital was \$4,509,798, and deposits, \$12,472,557. The number of fire, marine, and inland insurance companies authorized to do business in the State was 181, of which 8 were joint-stock and 2 mutual companies of Illinois, 146 joint-stock and 8 mutual companies of other States, and 17 foreign companies. The risks written in the State for the year 1877 by all companies (including 119 district, county, and township mutual fire-insurance companies) amounted to \$474,531,241. The total amount of premiums on insured property in the State during the year was \$4,908,265, and the losses paid, \$1,529,841, which is only 42 per cent of the premiums. The following table shows the valuation of property for the purposes of taxation, and the State debt, for a series of years: —

Year.	Real Estate.	Personal Property.	Railroad Property.	State Debt.
	\$	\$	\$	\$
1851	98,748,523	39,069,546		16,000,000
1855	231,590,084	95,927,235		15,190,000
1860	266,258,155	88,884,115	12,085,472	11,804,000
1865	262,114,308	116,302,235	13,911,393	11,178,000
1870	347,876,680	113,545,227	19,242,141	4,890,937
1871	336,244,708	113,915,561	25,516,042	1,892,496
1872	371,619,940	113,697,959	25,658,784	2,060,150
1873	809,434,748	398,119,271	133,807,823	1,706,750
1874	847,947,477	264,785,202	81,723,772	1,730,972
1875	789,208,982	235,834,418	60,496,456	1,480,582
1876	747,512,376	209,281,245	44,329,489	1,480,600
1877	700,096,143	189,465,922	41,637,243	1,442,464
1878	649,094,336	167,679,561	40,461,965	802,312

The State possesses an industrial university, which was opened to students of both sexes in 1868, and is situated at Urbana. The property and funds of this important institution amount to about \$800,000. It embraces schools of agriculture, horticulture, and fruit-growing; mechanical science, civil and mining engineering, and architecture; modern and ancient languages and literature; commerce; military science; and domestic science and arts. See Chicago.

**Illinois Central R.R.** runs from Cairo to Chicago, Ill., 364.73 m. and from Centralia to Dunleith, 340.77 m., total 705.50 m. The following lines are owned or leased by the Co., whose offices are in Chicago: The Kanawhee and South Western R.R., from Otto to Chatsworth, Ill., 36.76 m.; the Chicago and Springfield R.R., from Gilman, 1 m. distant from Chicago, to Springfield, 111.47 m.; the Dubuque and Sioux City R.R., from Dubuque to Iowa Falls, Ia., 142.89 m.; the Iowa Falls and Sioux City R.R., from Iowa Falls to Sioux City, Ia., 183.69 m.; the Cedar Falls and Minnesota R.R., from Waterloo, Ia., to State line, Minn., 75.58 m., being a total of 1,255.89 m. The Co. organized in 1851 has a controlling interest in the Chicago, St. Louis, and New Orleans R.R., by which the interest of the line is extended to New Orleans. The two roads connect at Cairo by means of a steamboat. *Financial statement:* Cap. stock, \$29,000,000; funded debt, \$10,397,000; 6% currency bonds secured by mortgage on Springfield Division, \$1,600,000, consisting of 1st mortgage 6% 20-year bonds, payable in 1898. State-

ment of funded debt in detail: Redemption currency 6% 25-year bonds, payable in 1890, \$2,500,000; sterling (£500,000) 6% 20-year bonds payable in 1895, \$2,500,000; sterling (£200,000) mortgage 5% 30-year bonds, payable in 1905, \$1,000,000; sterling (£2,000,000) sinking-fund 5% 30-year bonds, payable in 1903, \$4,393,000; construction 7% bonds payable 1875 (past due), \$4,000. Land department. In 1850 the States of Illinois, Mississippi, and Alabama received by act of Congress the grant of the right of way through the public lands and also three alternate sections of land on each side of the road for every mile of R.R. constructed and equipped, as aid towards the building of a railroad from Lake Michigan and the Upper Mississippi to the Gulf of Mexico. Up to 1879, 2,224,013.24 acres had been conveyed, leaving 370,986.76 acres unconveyed. 2,304,651.96 acres of the donated lands have been sold. The total amount of dividends paid to stockholders up to and including 1878 was \$34,835,347.

**Illinois Midland R.R.** runs from Terre Haute, Ind., to Peoria, Ill., 175.7 m. This Co., whose offices are in Terre Haute, was formed by the consolidation, in 1874, of the Peoria, Atlanta, and Decatur, the Paris and Decatur, and the Paris and Terre Haute R.R. Cos. In 1875 the road was placed in the hands of a receiver. *Financial statement:* Cap. stock, \$2,000,000; funded debts, \$4,175,000, consisting of 1st mortgage 7% bonds issued in 1875, payable in 1905, interest January and July.

**Illipe Oil, Illipoo, Ilpa, Epei Oil**, a light, greenish-yellow, aromatic oil expressed from the seeds of *Bassia longifolia*, a tree growing on the coasts of Coromandel and Bengal. In the fluid form it resembles palm-oil, and it becomes solid below 82° F. It is used in the East Indies for illumination, and for the manufacture of soap.

**Ill-Manned**, short-handed; a vessel that has not a proportionate number of seamen to her size and tonnage is said to be ill-manned.

**Illuminating**, a mode of painting or emblazoning books and manuscripts with ornamental letters. — Placing lights at the windows or in front of a house on festive occasions or days of rejoicing.

**Illuminating Oils.** See OIL.

**Illumination**, the act of illuminating or making luminous. For supplying artificial light to streets and the interior of houses, coal-gas and oil and fats are generally employed. These illuminating agents are compounds rich in carbon, upon the presence of which the brightness of their flames depends. Flame is gas or vapor heated to incandescence during the process of combustion. A flame containing no solid particles emits but a feeble light, even if its temperature is the highest possible. Pure hydrogen, for instance, burns with a pale, smokeless flame, though with the production of considerable heat. On the other hand, wax, kerosene, coal-gas, etc., while undergoing combustion, give out considerable light, because their flames contain innumerable solid particles of carbon, which act as radiant points.

To give the greatest degree of luminosity to flame, the supply of air must be proportioned to the character of the burning substance, and be insufficient for the instantaneous combustion of the evolved gases; in which case the hydrogen takes all the oxygen, and the larger portion of the carbon is precipitated, and burnt in the solid form, at some little distance within the outer surface of the flame. When the supply of air is sufficient for the immediate and complete combustion of the whole of the combustible matter, no such precipitation takes place, and the flame is neither white nor brilliant. The richest coal-gas, mixed with sufficient air to convert all its hydrogen and carbon into water and carbonic acid, explodes with a pale blue flash; yet the same gas, when consumed in the ordinary way, burns with a rich white flame. Every one must have noticed the effect of a gust of wind upon the flaring gas-jets of a butcher's shop; the plentiful supply

of air causes complete combustion, and so converts the bright white flames into dull blue streaks of fire. When the supply of air is insufficient to cause the combustion of the newly formed solid carbon at the instant of its development, and whilst it is in an incandescent state, the flame becomes red and smoky, and unburnt sooty particles are thrown off. The same occurs when the temperature of any portion of the hydrogen is reduced below that intensity required for the combustion of the newly separated charcoal. Solid bodies, as tallow, oils, and fats, which burn with flame, are converted into the state of gas by the heat required to kindle them, and it is this gaseous matter which suffers combustion, and not the substance which produces it. The following table exhibits the comparative cost of the light of 20 sperm candles, each burning 10 hours at the rate of 120 gr. per hour; also the amount of carbonic acid produced and heat evolved per hour, in obtaining this quantity of light:—

	Cost.	Carb. acid per hour in cubic feet.	Units of heat per hour.
	\$		
Wax .....	1.80 }	8.3	82
Spermaceti .....	1.65 }		
Paraffin candles .....	1.00 }	6.7	66
Tallow .....	0.75 }	10.1	100
Rock oil .....	0.15 }		
Kerosene .....	0.8 }	3.0	29
Coal-gas .....	0.5 }	5.0	47

These figures prove that coal-gas and the mineral oils are the cheapest and best illuminating agents, producing the largest amount of light with the least development of heat.

The light emitted by incandescent lime (*Drummond light*, *hydro-oxygen light*, *lime light*, *oxyhydrogen light*) is intensely brilliant, and is often made use of to enable workmen to continue operations at night. It is obtained by directing the flame produced by the combustion of a mixture of hydrogen (or coal-gas) and oxygen upon a small cylinder of lime. In the improved form of this light the lime is protected from crumbling by a cage of platinum wire, and is caused to rotate slowly by means of clock-work, so as constantly to expose a fresh surface to the flame. When reflected from a "parabolic mirror" in a pencil of parallel rays, the Drummond light has been recognized during daylight at a distance of 108 miles. The most powerful illuminator, however, is the *electric light*. See LIGHT (ELECTRIC).

**Illustration**, a woodcut or stereotype block; an impression taken therefrom.

**Illustrator**, a commentator; a draughtsman or designer.

**Image**, properly, an imitation or copy of anything; a likeness; a representation; a representation or similitude of any person or thing formed of a material substance. In commerce, this name is often applied to plaster casts or statues, and to figures in stone, wood, wax, or other materials.

**Imitation**, a counterfeit; a copy in inferior materials.

**Imitator**, a copyist; one who follows a set pattern.

**Immersion**, the act of plunging or dipping into a fluid.

**Immigrant**, a passenger who arrives in a country to settle; the term is only used when large bodies of passengers arrive together in vessels; when quitting they are termed emigrants, as they go forth to establish themselves elsewhere. See EMIGRATION.

**Immovables**, lands; houses; fixtures.

**Immunity**, a freedom from tax, office, or obligation, etc.

**Impediment**, an obstacle or hindrance to progress; an obstruction to navigation, or to any undertaking.

**Imperial**, relating to royalty. — Anything large, as a large kind of slate, a large portmanteau, etc. — A large-sized paper, 22 × 32 (printing-paper); 22 × 30 (flat writing-paper); 22 × 30 to 23 × 31 (blank-book paper).

**Imperial Bushel.** See BUSHEL.

**Imperial Drills**, linen fabrics, differing from ordinary drills in being woven with two threads

warp and three filling, while ordinary drills are single threads.

**Imperial Gallon.** See GALLON.

**Imperishable**, not subject to decay; indestructible, calculated to last long.

**Impermeable**, any textile substance rendered water-proof by the application of some solution, and a variety of other means. Petroleum, whitening, and water; alum, white-lead, and water; the same ingredients with acetic acid added; tar, as for tarpaulins; oil, as for oil-skin; a mixture of boiled oil, pipe-clay, burnt umber, white-lead, and pumice-stone; etc. Some special kinds have been applied to leather rather than cloth, such as a mixture of linseed-oil, suet, beeswax, and resin; a mixture of linseed-oil, resin, white vitriol, turpentine, and sawdust; a mixture of beeswax, Burgundy pitch, turpentine, and linseed-oil; and others in which tallow is a principal ingredient. But the chief water-proofing agent is india-rubber. Cloth saturated with this gum is extensively used for outer garments, life-jackets and belts, life-buoys, collapsible boats, beds, hammocks, mattresses, cushions, umbrella tents, portable bottles, shoes, and countless other articles.

**Impinge**, to fall or strike against.

**Implement**, tools; utensils; vessels; instruments; the tools or instruments of labor. "Wearing-apparel in actual use, and other personal effects (not merchandise), professional books, implements, and tools of trade, occupation, or employment of persons arriving in the U. States, are admitted free of duty. But this exemption shall not be constructed to include machinery, or other articles imported for use in any manufacturing establishment, or for sale." — *U. States Statutes, Section 2505.*

**Implicate**, to embarrass; to connect with.

**Important**, urgent; of great consequence.

**Importation and Exportation**, the bringing of commodities from and sending them to other countries. A very large portion of the revenue of the U. States being derived from customs duties, or from duties on commodities imported from abroad, and drawbacks being given on a few articles exported, the business of importation and exportation is subject to various regulations which must be carefully observed by those who would avoid incurring penalties, and subjecting their property to confiscation. The regulations referred to are embodied chiefly in Title xxiv of the Revised Statutes of the U. States (Edition 1878). We subjoin an extract of such portions of this which relate to the *entry of merchandise and payment of duties*, referring for other parts of the subject to the headings APPRAISEMENT, BILL OF LADING, DRAWBACK, INVOICE, MANIFEST, PORTS OF ENTRY AND DELIVERY, WAREHOUSING, etc.

*When vessels from foreign ports may enter and unlade.* It shall not be lawful to make entry of any such vessel elsewhere than at one of the ports of entry designated by law; nor to unlade the cargo, or any part thereof, elsewhere than at one of the ports of delivery, designated by law, except that every port of entry shall be also a port of delivery (Sec. 2770). — Vessels which are not vessels of the U. States shall be admitted to unlade only at ports of entry established by law; and no such vessel shall be admitted to make entry in any other district than in the one in which she shall be admitted to unlade (Sec. 2771). — The master of every vessel bound to a port of delivery only, in any district, shall first come to at the port of entry of such district, with his vessel, and then make report and entry in writing, and pay all duties required by law, port fees and charges, before such vessel shall proceed to her port of delivery. Any master of a vessel who shall proceed to a port of delivery contrary to such directions shall be liable to a penalty of \$500, to be recovered with costs of suit (Sec. 2772).

*Duty of making report on arrival.* — Within 24 hours after the arrival of any vessel, from any foreign port, at any port of

the U. States established by law, at which an officer of the customs resides, or within any harbor, inlet, or creek thereof, the master shall repair to such office, and make report to the chief officer of the arrival of the vessel; and he shall, within 48 hours after such arrival, make a further report in writing, to the collector of the district, which report shall be in the form, and shall contain all the particulars required to be inserted in, and verified like, a manifest. Every master who shall neglect or omit to make either of such reports and declarations, or to verify any such declaration as required, or shall not fully comply with the true intent and meaning of this section, shall, for each offence, be liable to a penalty of \$1,000 (Sec. 2774). — The master of any vessel having on board *distilled spirits or wines*, shall, within 48 hours after his arrival, whether the same be at the first port of arrival of such vessel or not, in addition to the requirements of the preceding section, report in writing to the surveyor or officer acting as inspector of the revenue of the port at which he has arrived, the foreign port from which he last sailed, the name of his vessel, his own name, the tonnage and denomination of such vessel, and to what nation belonging, together with the quantity and kinds of spirits and wines, on board of the vessel, particularizing the number of casks, vessels, cases, or other packages containing the same, with their marks and numbers, as also the quantity and kinds of spirits and wines, on board such vessel as sea-stores, and in default thereof he shall be liable to a penalty of \$500, and any spirits omitted to be reported shall be forfeited (Sec. 2775).

*Requisite of an entry of goods generally.* The owner or consignee of any merchandise on board of any such vessel, or, in case of his absence or sickness, his known agent or factor in his name, within 15 days after the report of the master to the collector of the district for which such merchandise shall be destined, shall make entry thereof in writing with the collector, and shall in such entry specify the name of the vessel and of her master, in which, and the port or place from which, such merchandise was imported, the particular marks, numbers, denominations, and prime cost, including charges of each particular package or parcel whereof the entry shall consist, or, if in bulk, the quantity, quality, and prime cost, including charges thereof, particularly specifying the species of money in which the invoices thereof are made out. Such entry shall be subscribed by the person making it, if the owner or consignee, in his own name, or, if another person, in his name as agent or factor, for the owner or consignee. The person making such entry shall also produce to the collector and naval officer, if any, the original invoices of the merchandise, or other documents received in lieu thereof, or concerning the same, in the same state in which they were received, with the bills of lading for the same; which invoices shall be signed by the persons in the offices of the collector and naval officer who have compared and examined them (Sec. 2785). — The entries to be made by any importer, consignee, or agent, under the preceding section, shall be verified by the oath of the person making the same (Sec. 2786).

*Bond by agent.* Whenever any entry is made with the collector of any district, of merchandise imported into the U. States subject to duty, by any agent, factor, or person, other than the person to whom it belongs, or to whom it is ultimately consigned, the collector shall take a bond with surety from such agent, factor, or person, in the penal sum of \$1,000, with condition that the actual owner or consignee of such merchandise shall deliver to the collector a full and correct account of the merchandise imported by him, or for him on his own account, or consigned to his care, in the same manner and form as required in respect to an entry previous to the landing of merchandise; which account shall be verified by a like oath, as in the case of an entry, to be taken and subscribed before any judge of the U. States, or the judge of any court of record of a State, or before any collector of the customs. In case of the payment of the duties at the time of entry, by any factor or agent, on the merchandise entered by him, the condition of the bond shall be to produce the account of the proper owner, or consignee, verified in manner as before directed, within 90 days from the date of such bond (Sec. 2787).

*Entry when particulars are unknown.* Where the particulars of any merchandise are unknown, in lieu of the entry prescribed above, an entry thereof shall be made and received according to the circumstances of the case; the party making the same declaring upon oath all that he knows or believes concerning the quality and particulars of the merchandise, and that he has no other knowledge or information concerning the same (Sec. 2788).

*Custody when invoice is imperfect.* Whenever an entry of merchandise is imperfect, for want of invoices, bills of lading, or for any other cause, the collector shall take the merchandise into his custody, until the quantity, quality, or value thereof, as the case may require, can be ascertained (Sec. 2789).

*Vessel's papers to be produced to collector.* The register, or other document in lieu thereof, together with the clearance and other papers granted by the officers of the customs to a vessel at her departure from the port from whence she may have arrived, Mediterranean passports excepted, shall previous to entry be produced to the collector with whom such entry is to be made, and shall remain in his office; and on the clear-

ance of such vessel the register and other documents shall be returned to the master or owner of such vessel (Sec. 2789).

**Entry of spirits and wines.** Every importer of distilled spirits or wines, or person to whom they are consigned, shall make a separate and additional entry thereof, specifying the name of the vessel, and her master, in which, and the place from which, such spirits or wines were imported, together with the quantity and quality thereof, and a particular detail of the casks or receptacles containing the same, with their marks and numbers; such entry shall be subscribed by the person making the same, for himself, or in behalf of the person for whom such entry is made, and shall be certified by the collector before whom it is made, as a true copy, and conformable to the general entry before directed, in respect to all distilled spirits and wines therein contained (Sec. 2794).

**Baggage and tools.** In order to ascertain what articles ought to be exempted, as the wearing-apparel and other personal baggage, and the tools and implements of a mechanical trade only, of persons who arrive in the U. States, due entry thereof, as of other merchandise, but separate and distinct from that of any other merchandise, imported from a foreign port, shall be made with the collector of the district in which the articles are intended to be landed by the owner thereof, or his agent, expressing the persons by whom or for whom such entry is made, and particularizing the several packages, and their contents, with their marks and numbers; and the person who shall make the entry shall take and subscribe an oath before the collector, declaring that the entry subscribed by him and to which the oath is annexed contains, to the best of his knowledge and belief, a just and true account of the contents of the several packages mentioned in the entry, specifying the name of the vessel, of her master, and of the port from which she has arrived; and that such packages contain no merchandise whatever other than wearing-apparel, personal baggage, or, as the case may be, tools of trade, specifying it; that they are all the property of a person named who has arrived, or is shortly expected to arrive, in the U. States, and are not directly or indirectly imported for any other, or intended for sale (Sec. 2799). — Whenever the person making entry of any such articles is not the owner of them, he shall give bond with one or more sureties, to the satisfaction of the collector, in a sum equal to the duties on like articles imported subject to duty, upon the condition that the owner of the articles shall, within one year, personally make an oath such as is prescribed in the preceding section (Sec. 2800). — Whenever any article subject to duty is found in the baggage of any person arriving within the U. States, which was not, at the time of making entry for such baggage, mentioned to the collector before whom such entry was made, by the person making entry, such article shall be forfeited, and the person in whose baggage it is found shall be liable to a penalty of treble the value of such article.

**Entry, etc., of cigars.** No cigars shall be imported unless the same are packed in boxes of not more than 500 cigars in each box; and no entry of any imported cigars shall be allowed of less quantity than 3,000 in a single package; and all cigars on importation shall be placed in public store or bonded warehouse, and shall not be removed therefrom until the same shall have been inspected and a stamp affixed to each box indicating such inspection, with the date thereof (Sec. 2803). See TOBACCO.

**Oaths, how taken.** All oaths to be taken upon making of any of the reports or entries, or respecting any of the acts mentioned in this chapter, whether by a master of any vessel, or the owner or consignee of any merchandise, his factor or agent, or by any other person, shall be administered by the collector, or officer to or with whom the report or entry is made, and shall be reduced to writing, and subscribed by the person taking and by the person administering the oath (Sec. 2805).

**Forfeiture when cost is not set forth in invoice.** If any merchandise, of which entry has been made in the office of a collector, is not invoiced according to the actual cost thereof at the place of exportation, with design to evade payment of duty, all such merchandise, or the value thereof, to be recovered of the person making entry, shall be forfeited (Sec. 2839).

**Collector to take possession when invoice is not correct.** In every case in which a collector shall suspect that any merchandise is not invoiced at a sum equal to that for which it has usually been sold in the place or country from whence it was imported, he shall take the merchandise into his possession, and retain the same with reasonable care, at the risk and expense of the owner or consignee, until its value at the time and place of importation has been ascertained, as in the case of damaged merchandise, or of merchandise not accompanied with an invoice, and until the duties arising, according to such valuation, have been paid, or secured to be paid. But in case of a prosecution for forfeiture, such appraisement shall not exclude other proof, upon the trial, of the actual cost of the merchandise at the place of exportation (Sec. 2840). See APPRAISEMENT.

**Oaths to accompany invoices.** Whenever merchandise imported into the U. States is entered into invoice, one of the following oaths, according to the nature of the case, shall be administered by the collector of the port, at the time of entry, to the owner, importer, consignee, or agent (Sec. 2841).

### 1. Oath of consignee, importer, or agent.

I, ———, do solemnly and truly swear (or affirm) that the invoice and bill of lading now presented by me to the collector of ———, are the true and only invoice and bill of lading by me received, of all the goods, wares, and merchandise imported in the ———, whereof ——— is master, from ———, for account of any person whomsoever, for whom I am authorized to enter the same; that the said invoice and bill of lading are in the state in which they were actually received by me, and that I do not know nor believe in the existence of any other invoice or bill of lading of the said goods, wares, and merchandise; that the entry now delivered to the collector contains a just and true account of the said goods, wares, and merchandise, according to the said invoice and bill of lading; that nothing has been, on my part, nor to my knowledge on the part of any other person, concealed or suppressed, whereby the United States may be defrauded of any part of the duty lawfully due on the said goods, wares, and merchandise, and that if, at any time hereafter, I discover any error in the said invoice, or in the account now rendered of the said goods, wares, and merchandise, or receive any other invoice of the same, I will immediately make the same known to the collector of this district. And I do further solemnly and truly swear (or affirm) that, to the best of my knowledge and belief, (insert the name and residence of the owner or owners,) is (or are) [the owner (or owners)] of the goods, wares, and merchandise mentioned in the annexed entry; that the invoice now produced by me exhibits the actual cost, (if purchased,) or fair market value, (if otherwise obtained,) at the time or times, and place or places, when or where procured, (as the case may be,) of the said goods, wares, and merchandise, all the charges thereon, and no other or different discount, bounty, or drawback, but such as has been actually allowed on the same.

### 2. Oath of owner in cases where merchandise has been actually purchased.

I, ———, do solemnly and truly swear (or affirm) that the entry now delivered by me to the collector of ——— contains a just and true account of all the goods, wares, and merchandise, imported by or consigned to me, in the ———, whereof ——— is master, from ———; \* that the invoice which I now produce contains a just and faithful account of the actual cost of the said goods, wares, and merchandise, of all charges thereon, including charges of purchasing, carriages, bleaching, dyeing, dressing, finishing, putting up, and packing, and no other discount, drawback, or bounty, but such as has been actually allowed on the same; that I do not know nor believe in the existence of any invoice or bill of lading other than those now produced by me, and that they are in the state in which I actually received them. And I do further solemnly and truly swear (or affirm) that I have not, in the said entry or invoice, concealed or suppressed anything whereby the U. States may be defrauded of any part of the duty lawfully due on the said goods, wares, and merchandise; and that if, at any time hereafter, I discover any error in the said invoice, or in the account now produced of the said goods, wares, and merchandise, or receive any other invoice of the same, I will immediately make the same known to the collector of this district.

### 3. Oath of manufacturer or owner in cases where merchandise has not been actually purchased.

As No. 2, except that at the place marked \* must be introduced the following: "That the said goods, wares, and merchandise were not actually bought by me; or by my agent, in the ordinary mode of bargain and sale, but, nevertheless," that the invoice . . . (continue as in No. 2.)

**Separate entry of packages contained in one importation.** A separate entry may be made of one or more packages contained in an importation of packed packages consigned to one importer or consignee, and concerning which packed packages, no invoice, or statement of contents or values has been received. Every such entry shall contain a declaration of the whole number of parcels contained in such original packed package; and shall embrace all the goods, wares, and merchandise imported in one vessel at one time for one and the same actual owner, or ultimate consignee. 2. The importer, consignee, or agent's oath prescribed by Sec. 2841 of the Revised Statutes (see above), is hereby modified for the purposes of this act, so as to require the importer, consignee, or agent, to declare therein that the entry contains an account of all the goods ———, imported in the ———, whereof ——— is master, from ———, for account of ———, with oath so modified, shall in each case be taken on the entry of one or more packages contained in an original package. But nothing in this act contained shall be construed to relieve the importer, consignee, or agent from producing the oath of the owner or ultimate consignee in every case, now required by law; or to provide that an importation may consist of less than the whole number of parcels contained in any packed package, or packed packages consigned in one vessel at one time, to one importer, consignee, or agent. 3. All provisions of law inconsistent herewith are hereby repealed (Act of Congress, May 1, 1876).

*Fond for production of invoice of goods of absent owner.* No merchandise subject to ad-valorem duty imported into the U. States, and belonging to a person residing in the U. States, but at the same time absent from the place where the merchandise is intended to be entered, shall be admitted to an entry, unless the importer, consignee, or agent, shall previously give bond, the form of which shall be prescribed by the Secretary of the Treasury, with sufficient sureties, to produce, within four months, to the collector of the port where the merchandise may be, the invoice of the same duly certified, according to the circumstances of the case, by the oath of the owner, or one of the owners; which oath shall be administered by a collector, if there is any in the place where the owner may be; or, if there is none, by some public officer duly authorized to administer oaths.

(For further prescriptions concerning invoices see Invoice).

*Suits to recover duties unduly paid.* Any person who shall have made payment under protest and in order to obtain possession of merchandise imported for him, to any collector, or person acting as collector, of any money as duties, when such amount of duties was not, or was not wholly, authorized by law, may maintain an action in the nature of an action at law, which shall be triable by jury, to ascertain the validity of such demand and payment of duties, and to recover back any excess so paid. But no recovery shall be allowed in such action unless a protest (in writing and signed by the claimant or his agent, was made and delivered at or before the payment, setting forth distinctly and specifically the grounds of objection to the amount claimed), and appeal to the Secretary of the Treasury shall have been taken within 30 days after the date of the ascertainment and liquidation of the duties by the proper officers of the customs (Sec. 3010).

*Limitation: bill of particulars.* No suit shall be maintained in any court for the recovery of duties alleged to have been erroneously or illegally exacted by collectors of customs, unless the plaintiff, within 30 days after due notice of the appearance of the defendant, either in person or by attorney, serves on the defendant or his attorney a bill of particulars of the plaintiff's demand, giving the name of the importer or importers, the description of the merchandise, and place from which imported, the name of the vessel, or means of importation, the date of the invoice, the date of the entry at the custom-house, the precise amount of duty claimed to have been exacted in excess, the date of payment of said duties, the day and year on which protest was filed against the exaction thereof, the date of appeal thereon to the Secretary of the Treasury, and date of decision, if any, on such appeal. And if a bill of particulars, containing all the above mentioned items, be not served as aforesaid, a judgment of non. pros. shall be rendered against the plaintiff or plaintiffs in said action (Sec. 3012).

*Refunding duties improperly collected.* Whenever it shall be shown to the satisfaction of the Secretary of the Treasury that, in any case of unascertained duties, or duties or other moneys paid under protest and appeal, as hereinbefore provided, more money has been paid to the collector, or person acting as such, than the law requires should have been paid, the Secretary of the Treasury shall draw his warrant upon the Treasurer in favor of the person entitled to the overpayment directing the Treasurer to refund the same out of any money in the Treasury not otherwise appropriated (Sec. 3012).

*Refunding duties upon failure to appeal.* Whenever it shall be shown to the satisfaction of the Secretary of the Treasury that more moneys have been paid to the collector of customs, or others acting as such, than the law requires, and the party has failed to comply with the requirements relating to appeals to the Secretary of the Treasury, and the Secretary of the Treasury shall be satisfied that such non-compliance with the requirements as above stated was owing to circumstances beyond the control of the importer, consignee, or agent making such payments, he may draw his warrant upon the Treasurer in favor of the person entitled to the overpayment (Sec. 3013).

**Imported**, a collective name for all goods and merchandise introduced from foreign countries.

**Importer**, one who receives goods, produce, manufactures, or merchandise from abroad, with the intent to sell them again.

**Importers and Traders**, a fire-insurance Co located in New York City, organized in 1859. Statement, Jan. 1, 1879: Cap. stock paid up in cash, \$200,000; surplus, \$111,828.32; risks in force, \$10,652,980; premiums, \$75,831.25; premiums received since the organization of the Co. \$1,227,306.86; losses paid, \$919,856.26; cash dividends paid to stockholders, \$286,000.

**Imports and Exports**, the articles imported into or exported from a country. The following table gives a complete view of the trade of the U. States with all parts of the world for a number

of years; and those dispersed through the work give a view of that trade in detail, that is, in particular articles and with particular countries.

*Value of merchandise imported into and exported from the U. States from 1859 to 1879 (gold and silver coin and bullion excepted).*

1879....	638,340,700	12,008,651	446,777,775	1,156,217,216

The above table shows that the total gold value of exports of domestic merchandise from the U. States had increased from \$275,166,697 in 1869 to \$698,340,700 in 1879, an increase of 154 per cent. With one or two unimportant exceptions, as seen in the following table, the U. States stands alone among the commercial nations in having an excess of exports over imports of merchandise. The increase in the value of our exports is derived mainly from breadstuffs, preserved meats, copper, live animals, agricultural implements, furs and fur-skins, distilled spirits, and refined sugar. Many other articles exhibit a large increase in the quantity exported, but a decrease in value, owing to their lower prices. The articles which show the greatest increase in the quantities exported are wheat, flour, oats, corn, rye, copper, cotton, petroleum and other oils, provisions, quicksilver, distilled spirits, starch, sugar, molasses, tallow, and leaf tobacco. The value of the exports of breadstuffs for the year 1879 amounted to \$210,355,528, and constituted 30 percent of the total value of our exports of domestic merchandise, while for the year 1873 the same amounted only to \$98,743,151. The almost unlimited capacity of the Western and Northwestern States for the production of cereals, in connection with the facilities for cheap transportation, has brought them in sharp competition with the older States and with foreign countries. Many products of American manufacture, previously exported in small quantities, or not at all, now find profitable markets in foreign countries, and some of these products are now exported to countries from which, a few years ago, they were largely imported into the U. States. The importation of merchandise into the U. States amounted to \$642,136,210 for the

year 1873 It fell to \$137,051,523, in 1878, and increased to \$415,777,775 in 1879, — an increase of \$3,726,252, or of two per cent as compared with the preceding year. The importation of railroad-bars declined from 531,537 tons in 1872 to 2,611 tons in 1879. The production of railroad-bars in

the U. States during the year 1878 amounted to 788,112 tons.

The values of imports into, and of domestic exports from, the principal seaports of the U. States during the years 1860, 1870, and 1878, are shown as follows: —

*Value of Imports at Seaports of the U. States.*

Total .....	\$7,460,100,000	\$6,466,000,000	100.00	

**Imposing-Stone**, the stone in a printing-office on which the pages or columns are arranged, and locked up in the chases, for press.

**Imposition**, an overcharge; a fraud. — That which is imposed by authority; as a tax, toll, duty, etc.

**Impost**, more commonly called *duty*, a tax or toll levied on goods imported.

**Impostor**, a cheat; one who defrauds.

**Impressing**, taking a copy of any work by printing, stamping, or marking with a die.

**Impression**, an effect made on any substance by a tool. — The copy taken from a die or seal. — The total number of sheets printed of a book or newspaper. — The copy of an engraving taken from a plate or wood block.

**Impressment**, a compulsory mode of obtaining seamen, for service in the navy, by a press-gang; sometimes still resorted to in Great Britain in time of war.

**Imprest**, an advance of public money to enable the person to whom it may be made to carry on some public service, — the term being used in opposition to final payment. The person to whom the advance is made is called the "imprest accountant." — *T. McElrath*.

**Imprimatur**, in countries subjected to the censorship of the press, a license to be granted by a public functionary appointed for the purpose before any book can be printed.

**Imprint**, the printer's name and address at-

tached to the first or last leaf of a book or printed sheet.

**Imprison**, to incarcerate; to deprive of liberty.

**Improvement**, an alteration in anything for the better; an advance in prices; increased activity or briskness in trade. — An addition of some useful thing to a machine, manufacture, or composition of matter.

**Patents**. The patent-law of July 4, 1836, authorizes the granting of a patent for any new and useful improvement on any art, machine, manufacture, or composition of matter. But it is often difficult to say what is a new and useful improvement, the cases frequently approaching very near to each other. In the present improved state of machinery, it is almost impracticable not to employ the same elements of motion, and in some particulars the same elements of operation, to produce any new effect.

**Improvident**, thoughtless, careless, inconsiderate.

**Inc. Ink**, a long measure of Japan, equal to 2½ yards.

**Incandescence**, a white heat; the appearance of metals when intensely heated.

**Incendiary**, one who sets fire to a dwelling-house, which crime, in law, is termed arson.

**Incense**, a name for odoriferous substances, used in churches, etc., for the purpose of producing aromatic or perfume odors. There is always a resin with an odoriferous gum, and the odor is developed by burning. Olibanum, styrax, benzoin, and cascarilla are used, but frankincense is the principal variety.

**Inch**, the twelfth part of a foot, and the smallest lineal measure to which a commonly recognized name is given; but subdivisions (generally decimal divisions) are used for many purposes. Formerly it was made to consist of 12 parts called lines, each of them being again divided into 12 parts called seconds, and so on.

**Inch-Stuff**, deal plank sawn to the thickness of an inch.

**Incineration**, the reduction of organic substances to ashes by combustion.

**Incision**, a cutting-mark or impression made on anything; the separation of the surface by a sharp instrument.

**Incisor**, a cutting tooth; those of the walrus, wild boar, hippopotamus, and some other animals, enter into commerce for ivory.

**Incline**, to lean over; to slope gradually, as an inclined plane.

**Inclusive**, comprehended in the number or sum.

**Incombustibility**, the property of being incapable of being kindled, or of being consumed by fire. Substances possessing this property are said to be incombustible, or fire-proof.

**Incombustible fabrics**. With a view of diminishing the danger of death by fire, to which women are more especially exposed, chemists have devoted considerable attention to the problem of rendering muslin and other light fabrics non-inflammable. This object may be obtained by steeping the fabric in almost any saline solution. Thus, cotton or linen stuffs prepared with a solution of borax, phosphate of soda, phosphate of ammonia, alum, or sal-ammoniac, may be placed in contact with ignited bodies without their suffering active combustion, or bursting into flame. The salts act by forming a crust of incombustible matter on the surface of the fibres. They do not, however, prevent carbonization taking place when the temperature is sufficiently high. It is by a knowledge of this property of culinary salt that jugglers are enabled to perform the common trick of burning a thread of cotton while supporting a ring or a small key, without the latter falling to the ground. The cotton is reduced to ainder, but from the action of the salt its fibres still retain sufficient tenacity to

support a light weight. — The addition of about 1 oz. of alum or sal ammoniac to the last water used to rise a lady's dress, or a set of bed furniture, or a less quantity added to the starch used to stiffen them, renders them uninflamable, or at least so little combustible that they will not readily take fire; and if kindled, are slowly consumed without flame. None of the above-named salts are adapted for fine soft muslins, which mostly require chemical treatment, because they injure the texture, rendering the fabric harsh and destroying all its beauty. The salt which is found to answer most completely all the required conditions is *tungstate of soda*. Muslin steeped in a solution containing 20% of this salt is perfectly non-inflammable when dry, and the saline film left on the surface is smooth and of a fatty appearance like talc, and therefore does not interfere with the process of ironing, but allows the hot iron to pass smoothly over the surface. The addition of a little phosphoric acid to the tungstate is recommended, for without this addition a portion of the tungstate is apt to undergo a chemical change and become comparatively insoluble. See ASBESTOS.

**Income**, a stipend; the receipts or gains derived from labor, business, or property of any kind; as from the produce of a farm; the rent of houses or land; the proceeds of literary or professional business; the profits of commerce or of occupation; the interest on funded property; or joint-stock securities. — *Gross Income* is the total amount or earnings and money from all sources accruing to the profit or use of a company, firm, etc., during a certain period, — usually one year. — *Net income* is obtained by subtracting from gross income all the expenses of the business, and the collected investments which form part of the receipts.

**Incomings**, receipts; money paid on entering upon a business, etc.

**Inconvertible**, not transmutable or changeable; some securities or investments are convertible into stock, etc.; others are not so.

**Incrustation**, a fur or sediment. — In building, work fixed with cement or cramp-irons into notches made to receive it.

**Steam Boilers' I.** With all qualities of water commonly used for feeding steam boilers there is a tendency to the production of hard calcareous deposits or layers of incrustation within the boilers, due to the separation of lime salts (particularly the carbonate and sulphate, or mixtures of these with a certain amount of carbonate of magnesia) as the direct consequence of the accumulation of these impurities from large quantities of water evaporated. The sparing solubility of the sulphate of lime (gypsum) in hot water fully accounts for its deposition in the boiler, and the carbonate of lime (chalk) is thrown down, not only as the result of direct evaporation, but by the ebullition expelling free carbonic acid, which holds this body to some extent in solution. Rain-water, which of itself is too pure to give rise to these incrustations, cannot be used *alone* for boiler purposes, for it has been found to exert a highly corrosive action upon the iron plates and fittings. It can, however, be advantageously employed in conjunction with "hail" spring or river waters, and has the effect of diminishing the incrustation merely as the result of dilution. The drain-pipes leading from the roof of the factory may be placed in connection with the tank or well from which the supply of water is drawn for the boilers. It will be seen hereafter that the self-same remedy is efficient both as a means of preventing incrustation and obviating corrosion, and that by using one of the alkaline substances about to be specified this twofold advantage may be secured. Iron will not rust when immersed in water containing a mere trace of caustic alkali, and it is a common observation that the iron vessels used in the preparation of potash and soda remain for any length of time free from all appearance of rust. This singular property is, no doubt, susceptible of important applications: amongst them may be mentioned the better protection of iron ships from the attack of bilge water, of hydraulic rams, moulding boxes, smith's tools, and other objects liable to be placed at times under the influence of water. Some forms of surface condensers become quickly corroded in consequence of the purity of the water accumulating in them by the process of distillation, and a small dose of caustic alkali is then useful as a means of protection; the engine-cylinders also to some extent are preserved when alkaline anti-incrustation fluids are introduced into the boilers, for the minute quantity which is carried forward mechanically in the form of spray mixed with the steam, suffices to preserve the iron. Whilst a tendency to "priming" undoubtedly results from a too liberal use of soda or other alkali in the boiler, it will in practice be found easy to adjust the proportion of this ingredient, so as to secure immunity from corrosion and incrustation, and at the same time avoid the

tumultuous kind of ebullition known as "priming." In all cases it is advisable to carry out a rigid system of inspection, and it is only in the way of saving fuel and labor that the application of boiler fluids is to be recommended. — Much benefit has often resulted from a coating of coal-tar or "dead oil" applied to the interior surfaces below the water line, when the boiler is opened for cleaning and inspection. These will tend very considerably to lessen the adhesion of calcareous crusts, and are not in any way affected by the boiler fluids in common use. Soda crystals and caustic soda may be used with great success in boilers to effect the immediate precipitation of the lime salts, and they act by throwing down a finely divided form of carbonate of lime, which in time furnishes nuclei for the deposition of subsequent accretions both of the carbonate and sulphate, so that they are prevented from crystallizing upon the walls of the boiler. A granular mud is thus formed, which subsides quickly and may be for the most part got rid of through the "blow-off cock," which should be opened for this purpose two or three times every day, and run out with as little water as possible.

The use of caustic soda has undergone a thorough trial in the boilers of the Royal Arsenal of Woolwich, England, and the following general instructions regarding its use are based upon an experience of upwards of ten years. The caustic soda should be dissolved in water so as to make a concentrated solution of sp. gr. 1.3. This, being perfectly miscible with water, may be introduced into the boiler with the feed-water at any time when, from the pressure of steam, it may not be convenient to pour it through the safety valve or other openings in the boiler. But when the steam is down there is no difficulty in introducing the prescribed dose by using a tin funnel with flattened aperture to pass it through the safety valve; or a tubular arrangement with double cocks will answer at all times. Half a gallon per diem is the average quantity found sufficient for a 20-horse stationary boiler, working with Thames water for ten hours daily. If the water should happen to be unusually hard a larger dose may be employed, but it would not be expedient to add in one charge more than the amount required for the day's consumption. Locomotive and multitubular boilers have been worked successfully with caustic soda, and it is here that the importance of using anti-incrustation fluids makes itself most apparent — Many other methods have at various times been proposed to prevent the formation of deposits in steam boilers, for which consult a pamphlet on "Boiler Incrustation and Corrosion," by F. J. Rowan, published by Spon, London.

**Incubator**, a machine for hatching eggs by artificial heat.

**Indebtedness**, the state of being indebted.

**Indelible**, not to be blotted out; that cannot be effaced or lost; as an *I. ink* which, when used upon linen or muslin, cannot be obliterated by washing; an *I. color*, which does not fade or tarnish by exposure.

**Indemnification**, act of indemnifying; reimbursement of loss or damage.

**Indemnity**, security or exemption from damage, loss, or injury; thus a policy of insurance is a contract of *I.* against any particular loss. Where one person also becomes bail for another, a bond of *I.* is frequently executed; and where a bond or bill of exchange has been lost or mislaid, the acceptor or obligee would not act prudently in paying it, without being secured by a bond of *I.*

**Indentation**, a notch or mark cut in anything, — running in and out like a row of teeth.

**Indenture**, a writing or deed comprising some contract between two or more parties.

**Index**, an alphabetical table of reference to the contents of a book, or to the accounts of a ledger.

— A pointer or needle which turns on a pivot. — The exponent of a power. — A directing post.

**Index-Hands**, the pointers of a clock, watch, or other registering machine.

**India (British)**. The British Empire in India extends over a territory as large as the continent of Europe without Russia. It is situated between lat. 8° and 36° 30' N., lon. 66° 30' and 99° E.; and is bounded N. by Chinese Turkistan and Thibet, from which it is separated by the Himalaya mountains, E. by Burmah and Siam, and W. by Beloochistan and Afghanistan. The entire coast of the country E. of Cape Comorin, the southern extremity of the Peninsula, is washed

by the Bay of Bengal, while the S. W. coast extends along the Indian Ocean and the Arabian Sea. From Peshawar, the northern frontier station, to Cape Comorin, the distance is 1,900 m, and the same distance separates Kurrachee, the port of Sind, from Sudiya, the frontier-post on the eastern border of Assam. Geographically the country may be broadly divided into Northern and Southern India. Northern India, or Hindostan, lying at the foot of the Himalayas, and stretching from sea to sea, comprehends the rich alluvial plains watered by the Indus, the Ganges, the Lower Brahmaputra, and their tributaries. Southern India, or the Deccan, is a plateau of triangular shape and very old geological formation, bounded on two sides by the Malabar and Coromandel coasts, which converge at Cape Comorin, and on the third by the Vindhya Mountains, north of the Narbaddah River. Three fifths of this great empire are under the direct rule of the British government, and the remaining two fifths are made up of a large number of native states, which, according to the last official reports, exceed 450 in number. Various frontier countries, like Nepal, merely acknowledge British superintendence, while others pay tributes or provide military contingents. New States are gradually drawn within the circle of British supremacy, either for the consolidation or the protection of the existing boundaries. The latest movement in this direction, toward the N. W., was the invasion of Afghanistan in 1879. The first general census of *B. I.* was taken during the years 1868 to 1876. The following table shows, according to the revised returns of this census, the area, population, and population by sq. m., of each of the divisions of India under British administration, and the total area and population of the feudatory States:—

Presidencies and Provinces under the Administration of—	Area in sq. miles.	Population.	Density of pop. to sq. mile.
<i>The Gov.-Gen. of India:—</i>			
Ajmere .....	2,711	396,889	146
Berar .....	17,728	2,226,496	126
Mysore .....	29,325	5,055,412	172
Coorg .....	2,900	168,312	84
<i>Governors:—</i>			
Madras .....	138,856	31,672,613	223
Bombay (including Sind)	123,142	16,302,173	132
<i>Lieutenant-Governors:—</i>			
Bengal .....	156,200	60,502,897	383

Total British Administration .....	908,350	191,018,412	210
Feudatory, or Native States .....	573,516	48,298,895	.....
Total British India .....	1,481,866	239,317,307	.....

The British-born population in India, exclusive of the army (which consists of about 60,000 men), amounted, according to the census taken in 1876, to 64,061 persons. Of these there were 38,946 of the male and 25,115 of the female sex. — The following table shows the number of Hindoos, Mohammedans, Buddhists, and Christians, in each of the provinces of India under British administration:—

Provinces.	Hindoos.	Moham'ns.	Buddhists	Christians
Bengal .....	38,975,418	19,553,831	84,974	90,793
Assam .....	2,679,597	1,104,101	1,521	1,947

The term "Presidency," which is applied to the provinces or governments of Bengal, Madras, and Bombay, is no longer a correct one, and in the case of Bengal is positively misleading. The expression is a relic of the time when the three settlements of Fort William, Fort St. George, and Bombay were each under the authority of a president, and comprised nearly the whole of the British possessions in India. Its use now frequently leads to the mistaken notion that British India still consists of three presidencies, whereas it is divided into provinces, each under its own civil government, and each independent of the others, but subordinate to the supreme government.

The present form of government of the Indian Empire is established by the Act 21 and 22 Victoria, cap. 106, called "An Act for the better Government of India," sanctioned Aug. 2, 1858. By the terms of this act, all the territories heretofore under the government of the East India Company are vested in the British sovereign, and all its powers are exercised in his name; all territorial and other revenues, and all tributes and other payments, are likewise received in his name, and disposed of for the purposes of the government of India alone, subject to the provisions of this act. One of the queen's principal secretaries of state, called the Secretary of State for India, is invested with all the powers hitherto exercised by the company or by the board of control. By Act 39 and 40 Victoria, cap. 10, proclaimed at Delhi, before all the princes and high dignitaries of India, Jan. 1, 1877, the Queen of Great Britain and Ireland assumed the additional title of *Indie Imperatrix*, or Empress of India. The executive authority in India is vested in a Governor-General or Viceroy, appointed by the Crown, and acting under the orders of the Secretary of State for India. The Governor-General, assisted by a Council of six members, has power to make laws for all persons, whether British or native, foreigners or others, within the Indian provinces, and for all subjects of the Crown within the dominions of the feudatory territories. Calcutta is the seat of government, and the residence of the Governor-General.

The occupations of the adult male population of *B. I.*, calculated to number 57,508,150, were classified as follows at the last enumeration:—

Classes.	Number of adult males
Government service and professions .....	2,464,855
Domestic occupations .....	4,137,429
Agriculture .....	37,402,220
Commerce .....	3,440,951
Industrial occupations .....	8,746,563
Laborers .....	8,174,600
Independent and non-productive persons .....	2,264,858
Total adult male population .....	57,508,150

In 1879 there were in *B. I.* 44 towns with over 50,000 inhabitants, as follows:—

Towns.	Pop.	Towns.	Pop.

The geographical features of India are distinguished at once by their grandeur and their variety. It is, as it were, an epitome of the whole world. Its vast plains present the double

with a single rock or even a hillock. The Ganges pours through it a continually widening stream, which, during the rainy season, covers a great extent with its fertilizing inundation. From this deep, rich, well-watered soil the sun awakens an almost unrivalled power of vegetation, and makes it one entire field of waving grain. Bahar, further up the current, has the same general aspect, though its surface is varied by some slight elevations; but Allahabad, higher still, is mostly low, warm, and fruitful, exactly like Bengal. North of the river the provinces of Oude and Kohleund, sloping gradually upwards to the mountains, enjoy a more cool and salubrious climate, and display in profusion the most valuable products both of Asia and Europe. Here the valley of the Ganges terminates, and is succeeded by that of the Jumna, more elevated, and neither so well watered nor quite so fertile. The Doab, or territory between the two rivers, requires in many places artificial irrigation. Its woods, however, are more luxuriant; while the moderate cold of its winter permits a crop of wheat or other European grain to be raised, and the summer is sufficiently hot to ripen one of rice. To the S. of the Jumna, and along the course of its tributary the Chumbul, the ground is broken by eminences, extending from the hills of Malwa and Ajmere; while, even amid its most level tracts, insulated rocks, with perpendicular sides and level summits, form those almost impregnable hill-forts, so much celebrated in Indian history. Westward of Delhi begins the Great Desert,—a sandy tract which intervenes between the tributaries of the Ganges on the one side and the Indus and its tributaries on the other, and which is refreshed only by a few small rivulets that sprang up and disappear amid the waste. This entire region, about 600 m. long and 300 broad, presents an aspect nearly similar to the most dreary parts of Arabia and Africa. To the N. and N. W. of this barren tract, however, lies the plain of the Punjab, where the five tributaries of the Indus, rolling their ample streams, produce a degree of fertility equal to that of the region watered by the Ganges. High cultivation, too frequently obstructed by public disorders, is alone wanting to

Fig. 283.—INDIAN COTTAGE.

harvest, the luxuriant foliage, and even the burning deserts of the torrid zone: the lower heights are enriched by the fruits and grains of the temperate climate: the upper steeps of the Himalayas are clothed with the vast pine forests of the north; while the highest pinnacles are buried beneath the perpetual snows of the arctic zone. The main body, as it were, of India, the chief scene of her matchless fertility, is composed of a plain, extending along the entire breadth from E. to W., between the Brahmapootra and the Indus, and reaching in point of latitude from the great chain of the Himalayas to the high table-land of the Southern Peninsula. It thus possesses a length of about 1,500 m., with an average breadth of from 300 to 400. With the exception, perhaps, of the country watered by the great river of China, it may be considered the finest and most fertile on the face of the earth. Of this general character of the Indian plain the province of Bengal presents the most complete and striking example, — no part of it being diversified

make it rival the finest portions of the more eastern territory. Throughout nearly the whole of this vast plain the wants of the population and the demands of commerce have superseded the original productions of nature: and, even under the most careful management, few of those exquisite shrubs are now reared which have given such celebrity to the vegetable kingdom of the East. Its staples consist of solid, rich, useful articles, produced by strong heat acting on a deep, moist, and fertile soil, — as rice, the Eastern staff of life, sugar, opium, indigo, and, in the drier tracts, cotton. Such an entire subjection to the plough and the spade, joined to the want of variety in the surface, gives to this great central region a tame and monotonous aspect. The Deccan, or Southern Peninsula, presents none of those singular features which distinguish the great central plain and its northern boundary. Hills, occasionally rising to the rank of mountains, and enclosing tablelands of various elevations, diversify its surface, and procure

for it at once the climate and vegetation of the tropical and of the temperate zones. But the most prominent feature is a range of heights, corresponding to the triangular form of this part of the continent. The N. border consists of the Vindhya chain, — a tract of high country stretching from the Gulf of Cambay to the Bay of Bengal, chiefly along both banks of the Nerbuddah, and composing the districts of Malwa, Candeish, and Gundwana, to which has been given the name of Central India. From its extremities extend southward the Ghauts, two parallel chains, which, at a greater or less distance, girdle the whole of the opposite coasts of Malabar and Coromandel. The Western Ghauts, rising from about 3,000 feet in the N. to 6,000 feet in the S., stand generally at a small distance from the sea. The chief productions of this district, which includes a great part of the Bombay presidency, are the pepper, vine, betel, and the areca, sago, and cocoa palms; while the highest tracts are crowned by forests of teak. At the boundary of Mysore there crosses the continent a ridge, called the Nilgierries, the loftiest in all this part of India, having one peak 8,700 feet in height, which has lately become an important sanitary retreat. Farther S., the W. coast is in general very low, and traversed by numerous streams flowing parallel to the shore, thus affording great convenience for inland navigation. The Eastern Ghauts, rising behind the Coromandel coast, and including a considerable portion of the Madras presidency, are generally less elevated, but spread into more numerous branches, and over a wider surface. They leave also a broader plain between them and the sea; yet, unless in the deltas of the great rivers which, from the W., cross the Ghauts and fall into the Bay of Bengal, this space bears somewhat of a naked and arid character. There occur even extensive tracts of sandy soil impregnated with saline substances, which in some degree taint the atmosphere. More to the N. in Orissa and the Circars, the high grounds often advance close to the sea, and consist to a great extent of mountain and jungle, continuing in a more uncultivated state, and peopled by more uncivilized races than almost any other part of India. Cuttack, again, a district approaching the Ganges, is so low as to be liable to frequent inundations from the sea. — These three ranges enclose a table-land, nearly 2,000 feet above the level of the ocean, and comprising the main body of Southern India. The S. W. tract, the original seat of Mahratta power, forms a hilly country; but the central region, composing the once powerful kingdom of Golconda and Bejapore, comprehends extensive fertile plains, secured by their elevation from the scorching heats which afflict the territory along the coast. The extreme southern district, called the Carnatic, is divided into two table-lands, the Ballahgaut and the Mysore, considerably higher than those of the Deccan, and on that account including a greater variety of climate, soil, and production.

Of the rivers, the largest have their source in the great northern chain of the Himalayas: and the rest, with few exceptions, in the table-land of Central and Southern India, which is supported by the Ghauts. The principal rivers, with the length of their respective course to the sea, are: Indus, 1,700 m.; Brahmaputra, 1,900 m.; Ganges, 1,500 m.; Jumna (to its junction with the Ganges, 780), 1,500 m.; Sutlege (to the Indus, 900), 1,490 m.; Guylum (to the Indus, 750), 1,250 m.; Gunduck (to the Ganges, 450), 980 m. In the Deccan, the Godavary, 850 m.; Kistna, 700 m.; Nerbuddah, 700 m.; Mahanuddy, 650 m.; Tuptee, 460 m.; and Cavery, 400 m. There are few coasts of such extent so destitute of islands and harbors as that of *B. I.* With the exception of emerged sea-banks and mere rocks, Ceylon is the only island near its shores: and on the E. coast, Masulipatan, which admits vessels of 300 tons burden, is the only harbor for large vessels between Trincomalee, in the island of Ceylon, and the Ganges, which is free from raging surf. To this inconvenience Madras, though an important port, is peculiarly liable. On the W. coast, the only harbors capable of admitting large vessels are Bombay and Kurrachee, in Seinde, Mangalore admits no vessels drawing more than 10 feet water.

**Climate.** *B. I.* comprehends within its bounds the opposite extremes of heat and cold. The plains are burnt up with intense heat; while winter, with every intermediate variety of temperature, prevails in the mountains. Philosophers have in vain endeavored to fix the point of perpetual congelation under different degrees of latitude. They have, indeed, framed a graduated scale of the respective heights at which, according to calculation, this point should begin at corresponding distances from the equator; but theory is here at variance with actual observation. The climate of mountainous tracts depends so much on localities, and the particular course of the winds, as to baffle all general speculation. Hence, on the Himalaya Mountains harvests of grain are found, where, according to hypothesis, the ground should be buried under deep snow; and trees are seen to flourish in the regions of perpetual winter. In northern Hindostan great and sudden changes of temperature occur, which is the cause of pulmonary affections. During summer the thermometer, which is often in the morning at 32° or under it, rises to 70°, 75°, and 80°, or upward, during the day; the winters are, however, uniformly severe. In this, also, as in other hilly countries, the traveller may be fainting to-day under a tropical sun, and shivering to-morrow amid the rigor of perpetual snows. From the banks

of the Sutlege, where the thermometer frequently stands at 100° and 108°, three days' climbing will carry him into the regions of winter. In the plains of Hindostan the heat during the greater part of the year is unintermitting and intense, except where it is modified by the ranges of mountains, or the table-lands towards the west. The seasons here are commonly divided into the hot, cold, and rainy. The spring and the dry season throughout the valley of the Ganges last about four months, the heat gradually increasing with the season, until, in May and June, the thermometer rises to 100° and frequently, in the interior, to 108° and 110°. when it is almost intolerable even to the natives, and still more so to Europeans, who resort to various modes of alleviation, such as the *cuscuta latty*, which is a frame of wood interwoven with twigs, between which is distributed a layer of a particular kind of sweet-scented grass. This being hung before an open window, in the quarter of the prevailing wind, and constantly moistened on the outside by a water-carrier, diffuses a refreshing coolness.

**Vegetable Produce.** *B. I.* comprehends all the known varieties of the vegetable tribes. The mountainous tracts of N. Hindostan produce all the Alpine plants and the various species of European grain, fruits, and flowers. Deep woods cover those lower ranges of mountains, in which are found the pine-tree of various species, the larch, the silver, and the spruce-fir, from the bark and twigs of which resin exudes in abundance; the yew-tree, several species of oak, holly, alder, sycamore, and birch, with mulberry and chestnut trees. These noble forests extend over immense tracts, and would afford inexhaustible supplies of timber if they could be transported to the proper market. Fruits in great variety are also produced in this elevated region, such as apricots, peaches, and grapes, apples, pears, currants, raspberries, blackberries, and strawberries; roots, such as turnips, carrots, garlic, and onions; flowers and plants, as roses, both red and white. Lilies of the valley, jasmynes, buttercups, yellow, blue, and white cowslips, and sweet-brier, with numerous other beautiful and fragrant plants. The valleys exhibit, according to their altitude and temperature, the productions of Europe or of the tropical countries. At the height of 6,000 feet above the oak and the pine; at that of 3,000 feet rattans and bamboos of enormous dimensions; in some parts the pine-apple, the orange, and the sugar-cane grow to maturity; in others, barley, millet, and similar grains are produced. The lower valleys yield rice, sown broadcast, maize, wheat, barley, pulse of various kinds, sugar-cane, cotton, Indian madder, a large species of cardamom, besides other productions. The pastoral tribes of Northern Hindostan feed considerable flocks on the lower hills and valleys; in summer they climb the Alpine country, and browse on the herbage adjacent to the region of perpetual frost. — Rice is the great staple of agriculture throughout Hindostan, in the plain of the Ganges as well as in S. India. It is sown at the approach of the rains, and it is gathered during the rainy season, about the end of August; the last crop is sown during the same season, and is gathered in the beginning of December. It is esteemed the best, not being equally liable with the other to decay. The diversity of soil and climate, and the several seasons of cultivation, have given rise to infinite varieties in this species of grain. When the rains fall throughout Hindostan, which occasionally happens, the rice crops are apt to be deficient to a degree altogether unknown in the well-regulated agriculture of Europe, where the severest scarcity hardly ever increases the price of corn more than three times its usual rate. But the famines of Hindostan leave thousands without subsistence, and fill the land with scenes of misery and death. Other kinds of grain are cultivated, such as Indian corn; and great varieties of pulse and coarse grains, such as peas, beans, chickpeas, gram, vetches, and raggy, which is the most important crop raised in the dry field, and in some parts of S. India is the subsistence of all classes, in others of the poorer classes. These are important articles of cultivation, as they have each their particular season, and thrive even on poorer soils. Maize is the general produce of poor soils in hilly countries, and is commonly cultivated in the more western provinces. Millet and other grains are also cultivated, and, vegetating rapidly, in every season they fill up profitably for the farmer the short intervals between the other modes of cultivation in lower Hindostan. Sugar is everywhere cultivated, and at little expense by the Hindoo cultivator: it grows luxuriantly throughout all the valleys of the Ganges, and in the plains of S. India, and could be produced, with the help of European skill, to meet any demand. Opium, which is a government monopoly, is extensively cultivated in many parts of Hindostan. It is a precarious crop, producing alternately high profits and heavy losses. The cotton plant has from time immemorial been one of the staple products of Hindostan, and is indigenous from Ceylon in the S. to the Himalaya Mountains. It is cultivated extensively, raised in the Doab and others of the upper Gangetic provinces, from which Bengal is almost entirely supplied; but the best qualities are found in the Nagpore district, and in the vicinity of Surat and Bombay. These, however, have continued to be inferior to the American, as they are frequently rendered unmarketable by their foul state, being mingled with dirt and seed. Great exertions have been made by the government to im-

prove the quality; experimental farms have been established; seeds of the American and Egyptian species have been introduced, also cleaning implements, particularly our saw-gin. Its application appeared at first completely successful; but it was soon found that it shortened the staple. It appears on the whole, however, that European superintendence, with an improvement in the native modes of cleaning and packing, has of late raised the value. Silk is another material native to India; and, though its actual culture is not so widely diffused as that of cotton, it could probably be produced in almost any desired quantity. Cossimbuzar, Commercy, and Rungpore are at present the principal districts whence it is derived. Tobacco has been planted by Europeans, and is in general use. The chief other products are: indigo, extensively grown along the alluvial tracts of Bengal, bordering on the Ganges; pepper, raised amid the wooded hills of Malabar and Canara; salt-petre, an article of which Bengal, from some peculiarity in its soil and climate, enjoys nearly a monopoly; and wool, which was always produced, though, till lately, of very inferior quality. In the territory of Bombay it has been remarkably improved.

**Minerals.** Coal, iron, and salt are the most important and abundant mineral products. The principal coal-fields are in the valley of the river Damooda, N. W. of Calcutta, where they occupy an area of 1,500 sq. m. Iron is widely distributed throughout the country; and salt is procured in immense quantities and of remarkable purity from the salt range of the Punjab. Gold is found in the gravel of streams, but only in small quantities. Lead is obtained from the N. W. Himalaya districts, and there is a considerable yield of copper in Gur-whal, Nepal, and Sikkim, and near Singbhoon in Bengal. Antimony occurs abundantly in N. India; there are valuable tin-mines in British Burmah, and petroleum has been discovered in the Pegu district of that province. Among the gems found in India are the diamond, ruby, topaz, beryl, carnelian, and garnet.

**Manufactures.** The Indian manuf. have enjoyed a high reputation from the earliest antiquity. The country containing a great number of inhabitants who are extremely poor, and a few who are immensely rich, a demand is created on the one hand for a great mass of coarse fabrics, and on the other for a small quantity that are exquisitely fine. To exhibit themselves in splendid robes is a favorite object of Oriental luxury; accordingly, the produce of the loom had reached a perfection to which that of no other country, except Britain, and that very recently, could make even an approach. The delicate and flexible form of the Hindoo, the pliancy of his fingers, and the exquisite sense with which they are endowed, even his quiet indefatigable perseverance, all render him peculiarly fitted for this description of employment. The muslins of Dacca in fineness, the calicoes and other piece goods of Coromandel in brilliant, durable colors, have never been surpassed; and yet they are produced without capital, machinery, division of labor, or any of those means which give such facilities to the manufacturing skill of Europe,—the weaver being merely a detached individual, with a loom of the rudest construction, consisting sometimes of a few branches of trees or bars of wood roughly put together. The demand for these fine muslins and calicoes, however, has within the last fifty years greatly decreased, owing partly to the fall of so many splendid courts where alone remunerating prices could be obtained, but mainly to the competition of the cheap imitations of these fabrics, which are imported from Manchester, Glasgow, and Paisley. The only cloths that now meet a sure sale are those coarse cotton robes woven in almost every inland village, for the use of the common people. The sole other manufacture deserving of notice is that of silk, which is also of great antiquity in India, and carried to considerable perfection, though not nearly equal to that of cotton. Bandanas and other handkerchiefs, crapes and taffetas, are the forms in which it is chiefly produced. The shawls of Cashmere are also highly prized in every quarter of the world.

**Inland Trade** comprehends not only the intercourse between the British Provinces, and the trade of the latter with the tributary States, but also the trade along a land frontier of about 2,000 m. with Afghanistan, Turkistan, and Thibet. This trade is very great, and has been vastly developed of late years by the construction of several great lines of railroads; but there are only meagre statistics concerning it.

**Foreign Trade.** From the reputed wealth and precious produce of India, foreign nations were always desirous to participate in its trade. Prior to Alexander's expedition to the East it was scarcely known to the Greeks, nor is it certain that they had ever seen its productions. But we know that these were brought to Rome, especially silk, which so allured the vanity of the Roman ladies that it sold for its weight in gold. Other valuable commodities of India, such as calicoes, muslins, aromatics, ivory, diamonds, pearls, and other gems, precious aromatics, the pepper of Malabar, turtle shell, etc., and some dry sugar and indigo, were also imported into Alexandria, the chief emporium of eastern commerce, and were naturally attracted to the great metropolis of the ancient world. This trade was carried on from Myos Hormos, the chief port on the Red Sea, whence, after the conquest of Egypt by the Romans, the annual fleets, sometimes of 120 vessels, set sail, and, under the propitious influence of the S. W. monsoon, boldly stretched

across the Indian Ocean for the western coast of Hindostan, which they reached in about 40 days; and afterward extended their voyage round Cape Comorin to the coast of Coromandel and the mouths of the Ganges. The high price received for these eastern luxuries in Rome encouraged the merchants to provide larger vessels, and a band of archers to defend them against the pirates, who then, and until very lately that they were extirpated by British ships of war, infested the western shores of India. The commodities of the East, being landed at Myos Hormos, were carried on camels to Coptos, the seat of a flourishing trade, and thence by sea to the Nile, whence they reached Alexandria by water carriage, and were reshipped to the different ports on the Mediterranean. The produce of India was also brought to Europe by other routes,—namely, by the way of Palmyra, then a flourishing city, and thence to Rome and other western countries, through the ports of Syria. But though there was a demand in Europe for the produce of India, there was no demand in India for the produce of Europe; and bullion was the only article that could be sent out in exchange. The annual drain of gold from Rome and its provinces for Indian goods was estimated by Pliny at 500 sesteria, equal to about \$2,000,000. In the convulsions which followed the decline of the Roman Empire, the trade of the East was successively engrossed by the Persians and Arabians. The latter, in the year 636, built the city of Bassora, which soon grew into a great commercial mart; and to this place, and to Ormuz, long celebrated for its vast riches and its trade, the spices and merchandise of India were brought and distributed through the various ports of the Mediterranean. After the expulsion of the crusaders from Syria and Egypt, Alexandria again became the chief entrepôt of eastern produce, whence it was carried to Italy by the Venetians and others, and distributed throughout Europe. But the discovery of a passage to India in 1495 by the Cape of Good Hope changed the course of this trade, which now entirely left the Italians, and was engrossed by the Portuguese for nearly a century without any molestation from European rivals. At length the Dutch and the English became their competitors, and established joint-stock companies, with the exclusive privilege of the eastern trade. But their anticipations of profit were not realized. The great distance of Europe from India, and the want of an equivalent for its produce, precluded any extensive intercourse; the trade accordingly bore a very small proportion to the trade of the country; and being besides cramped by monopolies, it never attained its natural growth. The commerce of nations is limited to the surplus produce which they can mutually exchange; and, from the great distance between India and Europe, this surplus produce was long confined to those few articles which, containing a great value in small bulk, could bear the expense of a long voyage. The demand was also altogether on the side of Europe, and its trade with India consisted merely in the purchase, with bullion, of a small quantity of precious articles for the consumption of the rich. The progressive improvement of industry in Europe, together with the entire opening of the trade to India and China since the year 1834, has occasioned not only a greater exportation of British goods, but a change also in the nature of the trade. It is not so much the produce of the labor as of the climate and soil of India, which no ingenuity can supply, that is in demand in Great Britain; and, accordingly, while the import of Indian manufactures has fallen off, that of the raw material, and many varieties of vegetable produce, has increased. Thus, in the progress of the trade between India and Europe, the former country, notwithstanding its boasted wealth and superior industry, has taken the lowest place, exporting her rude produce for the manufactures of the richer country; and so prodigious have been the improvements in European manufactures, that the raw material of cotton, being exported from India to England, and manufactured there, was, and is still, to a certain extent, re-exported and sold at a cheaper rate than the home fabrics, though loaded with the expense of a double voyage across half the globe. The total value of the imports and exports of *E. I.* was as follows in each of the ten years from 1868 to 1877:—

Years.	Imports.		Exports.	
	Merchandise.	Bullion and Coin.	Merchandise.	Bullion and Coin.
	£	£	£	£
1868.....	35,705,783	11,775,374	50,874,056	1,571,946
1869.....	35,990,142	15,155,954	53,062,165	1,395,580
1870.....	32,927,520	13,954,807	52,471,376	1,042,353
1871.....	34,469,119	5,444,823	55,336,186	2,220,765
1872.....	32,091,850	11,573,813	63,189,732	1,495,642
1873.....	31,874,625	4,556,515	55,231,463	1,308,579
1874.....	33,836,028	5,792,534	54,981,561	1,958,512
1875.....	36,222,087	8,141,047	56,359,230	1,625,309
1876.....	38,887,340	5,300,722	58,091,495	2,200,236
1877.....	37,440,631	11,436,120	61,013,891	4,029,898

About 50 per cent of the imports and exports come from and go to Great Britain. The chief articles of British produce im-

ported to India are cotton goods and iron. The most important articles of export from India to Great Britain are raw cotton, jute, rice, flax and linseed, tea, and untanned hides. The quantities, and still more the value of the exports of raw cotton are gradually decreasing. The following table exhibits

with India are, in order of importance, China, the Straits settlements, Ceylon, France, and the U. States.

The commerce of the U. States with *B. I.*, principally confined to the ports of Calcutta and Bombay, was as follows for the 20 consecutive years from 1859 to 1878:—

Fig. 284. — THE MAUSOLEUM OF AKBAR, NEAR AGRA.

the quantities and value of raw cotton exported from India to Great Britain in each of the ten years from 1868 to 1877:—

Years.	Quantities.	Value.
	Cwt.	£
1868.....	4,898,119	15,975,568

1877.....	1,725,582	4,230,803

The flow of the precious metals into India has for ages been a remarkable feature of the commerce of that country; it is yet very large, though it has been greatly on the decrease in recent years.

From 1835 to 1875 the value of merchandise exported from India was about 1200 millions sterling, against 700 millions of imports. To meet this balance in favor of India, the treasure imported was £313,331,593 (\$1,716,657,965), against £43,618,669 (\$218,003,345), exported; £162,063,824 (\$810,319,120) were remitted to India by bills of exchange drawn in England, leaving a balance of about 38 millions.

Next to Great Britain, the countries having the largest trade

The value of the principal articles imported from and exported to the U. States, for the year 1878, was as follows:—

**Imports:** Indian corn, \$18,050; cotton goods, \$78,841; drugs, etc., \$10,820; fruits preserved in cans, \$5,985; silver bullion, \$52,350; ice, \$87,470; naval stores, \$18,571; mineral oil, \$532,137; lard, \$7,500; soap, \$5,490; spirits of turpentine, \$42,046; tobacco, \$29,131. — **Exports:** Chemicals, dyes, etc. (entry free), \$293,026; coffee (1,269,557 lbs.), \$196,925; catechu (24,238,310 lbs.), \$960,437; gums, \$318,647; hides and skins, \$2,039,144; india-rubber, \$100,307; indigo, \$825,099; fixed oils, \$63,917; volatile oils, \$33,077; rags, \$29,623; tin in bars, \$807,103; woods (unmanuf.), \$98,335; flax (manuf. of), \$73,956; jute (raw), \$1,533,298; jute (manuf. of), \$502,349; leather, \$109,047; saltpetre, \$270,732; linseed (1,200,269 lbs.), \$1,882,953; spices, \$785,517; brown sugar (16,194,232 lbs.), \$725,907.

In 1878, 22 American vessels (tonnage 24,072) entered, and 24 (tonnage 26,169) cleared, the ports of B. I.; 69 foreign vessels for B. I. (tonnage 70,599) entered, and 4 (tonnage 2,572) cleared, the ports of the U. States.

**Finances.** The revenue and expenditure of the Indian Empire are subjected to the control of the Secretary in Council, and no grant or appropriation of any part of the revenue can be made without the concurrence of a majority of the Council. Such parts of the revenues of India as may be remitted to England, and moneys arising in Great Britain, must be paid into the Bank of England; and paid out on drafts or orders signed by three members of the Council, and countersigned by the secretary or one of his under secretaries. The subjoined table gives the total gross amount of the actual revenue and expenditure of India, in each of the ten fiscal years, ending March 31, from 1868 to 1877.

Years.	Revenue.	Expenditure.		Total Expenditure.
		In India.	In Great Britain.	
	£	£	£	£
1868	48,534,412	41,044,485	8,497,622	49,542,107
1869	49,262,691	42,207,629	9,829,092	52,036,721
1870	50,901,081	41,363,021	9,419,391	50,782,412

1877	55,955,785	44,710,800	13,467,763	58,178,563

The most important source of public revenue to which rulers in India have, in all ages, looked for obtaining their income is the land, the revenue from which, in the year before the Mutiny, furnished more than one half of the total receipts of the East India Company's treasury. At present, when the necessities of the Indian exchequer require that government should resort more largely to the aid of duties levied on the continually increasing trade of the country, the revenue from land produces not quite so much in proportion, but it still forms two fifths of the total receipts of the Empire. Next in importance to the land-revenue, as a great source of Indian receipts, is the income derived from the *opium monopoly*. The cultivation of the poppy is prohibited in Bengal, except for the purpose of selling the juice to the officers of the government at a certain fixed price. It is manufactured into opium at the government factories at Patna and Ghazipur, and then sent to Calcutta, and sold by auction to merchants who export it to China. In the Bombay presidency the revenue is derived from the opium which is manufactured in the native states of Malwa and Gujerat, on which passes are given, at the price of £60 per chest, weighing 140 lbs. net, to merchants who wish to send opium to the port of Bombay. The poppy is not cultivated in the presidency of Madras. The gross revenue derived from opium averaged during the ten years from 1867 to 1876 the sum of eight millions sterling.

The amount of the *public debt* of India, including that incurred in Great Britain, and treasury notes, etc., in 1878, was £138,965,025 (\$694,675,125). The total interest on debt and obligations amounted to £4,907,236 (\$24,536,180).

The *currency* of India is chiefly silver, and the amount of money coined annually is large. On July 16, 1861, an act was passed by the government of India, providing for the issue of a paper currency through a government department of Public Issue, by means of promissory notes. Circles of issue were established from time to time, as found necessary, and the notes were made legal tender within the circle in which they were issued, and rendered payable at the place of issue, and also at the capital city of the presidency within which that place was situated. Under the provisions of further laws, consolidated by a statute known as Act 111. of 1871, the issue was regulated in seven descriptions of notes, namely, for 10,000 rupees, or £1,000; for 1,000 rupees, or £100; for 500 rupees, £50; for 100 rupees, or £10; for 50 rupees, or £5; for 20

rupees, or £2; for 10 rupees, or £1, and for 5 rupees, or 10s. In 1878 the total amount of notes in circulation was £11,641,654 (\$58,208,270).

**Railroads.** In the year 1845 two great private associations were formed for the purpose of constructing lines of railroad in India; but the projectors found it impossible to raise the necessary funds for their proposed schemes without the assistance of the State. It was therefore determined by the Indian government to guarantee to the railway companies, for a term of 99 years, a rate of interest of 5 per cent upon the capital subscribed for their undertakings; and, in order to guard against the evil effects of failure on the part of the companies, power was reserved by the government to supervise and control their proceedings by means of an official director. The lands are given by the government free of expense, and the stipulated rate of interest is guaranteed to the shareholders in every case, except that of the traffic receipts of the line being insufficient to cover the working expenses, in which event the deficiency is chargeable against the guaranteed interest. Should the net receipts be in excess of the sum required to pay the guaranty, the surplus is divided in equal parts between the government and the shareholders, until the charge to the government for interest in previous years, with simple interest thereon, has been repaid, after which time the whole of the receipts are distributed among the shareholders. The government has the power, at the expiration of a period of 25 or 50 years from the date of the contracts, of purchasing the railways at the mean value of the shares for the three previous years, or of paying a proportionate annuity until the end of the 99 years, when the whole of the lands and works will revert from the companies to the government. In 1869 the government of India decided on carrying out all the new railway extensions by means of direct State agency, that is, without the intervention of guaranteed companies.

The following table shows the length of the various lines of railroad open for traffic, and in course of construction, in 1878:—

RAILROADS.	Open for traffic, 1878.	Total open or under construct.
	Miles.	Miles.

<b>Total, Indian railroads</b>	<b>7,324</b>	<b>8,609</b>

The number of passengers carried on the railroads of India largely increased in the course of 10 years, rising from 16,875,978 in 1869, to 36,711,514 in 1878. According to an official report for the same year, the total outlay upon railroads, both State and guaranteed, amounted to £110,005,044 (\$550,025,220) at the end of 1878.

Money:—		£	s.	d.
The Mohur of Bengal, average rate of exchange	.....	1	13	6½
" Mohur of Bombay	"	1	10	1½

The sum of 100,000 rupees is called a "lac," and of 10,000,000 a "crore," of rupees.

In 1835 the government remodelled the currency of India, establishing a more uniform system, in conformity with which accounts are mostly kept at present in rupees, reckoned of the value of 2 shillings. Silver is the only legal tender and standard of value.

#### Weights and Measures.

" <i>Guz</i> of Bengal.....	= 36 inches.

An Act "to provide for the ultimate adoption of an uniform system of weights and measures of capacity throughout British India," was passed by the governor-general of India in council in 1871. The Act orders: Art. 2 "The primary standard of weight shall be called a *seer*, and shall be a weight of metal in the possession of the government of India, equal, when weighed in a vacuum, to the weight known in France as the kilogramme." Art. 3. "The units of weight and measures of capacity shall be, for weights, the said *seer*; for measures of capacity, a measure containing one such *seer* of water at its maximum density, weighed in a vacuum." Unless it be otherwise ordered, the subdivisions of all such weights and measures of capacity shall be expressed in decimal parts."

**Seaports.** The only three ports of importance for British interests are Calcutta, Bombay, and Madras, here given in their alphabetical order:—

**Bombay**, a city, seaport, and capital of the presidency or province of the same name, is situated on a narrow neck of a small land at the S. E. extremity of the island of Bombay. The island consists of a plain about 11 m. long by 3 broad, flanked by two parallel lines of low hills. A neck of land stretching towards the S. W. forms the harbor on its E. side, sheltering it from the force of the open sea, and enclosing an expanse of water from 5 to 7 m. wide. At the S. W. of the island Back Bay, a shallow basin rather more than 2 m. in breadth runs inland for about 3 m. between the extreme points of the two ranges of hills. On a slightly raised strip of land between the head of Back Bay and the harbor is situated the fort, the nucleus of the city of Bombay. From this point the land slopes westward towards the central plain, a low-lying tract, which before the construction of the embankment known as the Hornby Velard used at high tide to be submerged by the sea. To the N. and E., although causeways and railway embankments have now shut out the sea, a large area of salt-marsh land still remains subject to inundation. The splendid harbor of Bombay and comparative nearness to the Suez Canal, with the system of railways which now connect Bombay with the other provinces, have marked out for it a career scarcely second, if at all second in commercial importance, to that of Calcutta itself. The sudden demand for Indian cotton, which resulted from the American war, gave an unprecedented rapidity to its development. The cotton of Gujerat, Dharwar, and other parts of Bombay, is much superior to the Bengal fibre. Several years of brilliant prosperity culminated in 1866-7 in a financial crisis, that left the commerce of Bombay in a shattered state. Depending as it does chiefly on the one article of cotton, along with some export of grain and the government opium, the trade of Bombay rests on a narrower basis than that of Calcutta, which in years of misfortune has a large variety of staples to fall back upon, such as tea, indigo, jute, rice, hides, oil-seeds, etc. Moreover, Bombay has only the costly railway communication with the interior parts of India, while Calcutta commands the confluence of two of the greatest river systems in the world, the Brahmaputra and the Ganges. Nevertheless, Bombay is pressing close upon Calcutta as the commercial capital of India, its imports and exports being even greater. In 1873 its total foreign trade was \$243,491,155, against a total of \$230,035,640 in Calcutta. In natural scenery and in sanitary advantages of its position Bombay ranks first among the cities of India. The Bombay Island, or, as it ought to be more correctly called, the Bombay Peninsula, is now connected with the mainland by the railway causeways. It stands out from a coast ennobled by lofty mountains, and its harbor is studded by rocky islands and precipices, whose peaks rise to a great height. The approach from the sea discloses one of the finest panoramas in the world,—the only European analogy being the Bay of Naples. The town itself consists of well-built and unusually handsome native bazaars, and of spacious streets devoted to European commerce. In the native bazaar the houses rise three or four stories in height, with elaborately carved pillars and front work. Some of the European hotels and commercial buildings are on the American scale, and have no rival in any other city of India. The private houses of the European residents lie apart alike from the native and from the mercantile quarters of the town. As a rule, each is built in a large garden or compound; and although the style of architecture is less imposing than that of the stately residences in Calcutta, it is well suited to the climate, and has a beauty and comfort of its own. Though in general cooled by the sea-breeze, the temperature in Bom-

bay is oppressively hot during May and October. A new future has lately been opened to manufacturing energy by the introduction of machinery from England. The ancient products of the presidency above named are chiefly household industries. But large steam-mills are now rapidly springing up in Bombay city, Broach, Surat, and other stations on the railway lines, especially in the cotton districts. Several of these employ over 1,500 hands, one is reported to have nearly double that number; and the low rates of wages, with the natural aptitude of the native for textile work, enables the Bombay mill-owners to compete with the Lancashire manufacturers, notwithstanding the heavy cost of importing machinery and of European supervision. Several of the mills have a capital of some hundreds of thousands sterling invested in them; and their superior reputation for turning out unglazed and genuine goods has almost driven the lower qualities of Manchester fabrics from the market. In 1873 fifteen mills were at work in the town and island of Bombay, and five in other parts of the presidency. Most of them have both spindles and looms, and their yarn and piece goods find a ready market. In Ahmedabad, Surat, Yeola, Nasik, and Bombay, considerable quantities of silk goods are made, the silk being imported from China either in the cocoon or in skeins. Gold and silver thread enter largely into the manufacture of silk and cotton fabrics. The *kinkhab* (kincoob), the richest kind produced, is either gold thread and silk, or silver, gold, and silk. Embroidery in silk cloth and cotton, and in gold, silver, and silk thread, is carried on to some extent in Hyderabad, in Sind, principally for European markets. Fibres are used for the manufacture of paper in Ahmedabad, Baroda, Surat, Kasik, Bombay, and Kolhapur. Mats, beds, etc., are manufactured from cocoa-nut fibre. Leather is worked into a variety of articles throughout the presidency. The manufactures of minor importance consist of pottery, brass and copper utensils, cutlery and agricultural implements, gold and silver ornaments, carved wood, ivory work, etc. In 1873, 5,611 ships, having a tonnage of 1,127,216 tons, cleared from Bombay harbor. Bombay is the only port of consequence in British India in which the rise and fall of the tide are so considerable as to admit of the formation of extensive wet docks. At ordinary spring-tides the rise is about 14 feet, but occasionally as high as 17. The capacious docks constructed by the East India Company are their property, and are for the most part under the direction of Parsees, who, excepting the Chinese, are the most industrious and intelligent people of the East. Merchant vessels of the largest class, or from 1,300 to 1,400 tons burden, for the cotton-trade to China, have been built in these docks. The timber having to be brought from a great distance, ships built at Bombay are very costly; but being, contrary to the practice in other parts of India, entirely constructed of teak, they are the most durable vessels in the world, requiring little repair, and often running 50 or 60 years. Being for the most part built by natives, without any very strict application of the rules of art, they are commonly, though not always, heavy sailers.—**Banks.** These consist of the Chartered Mercantile Bank of India, and the Chartered Bank of India, and branches of the Oriental Bank of London, the Agra Bank, etc. Including agencies of English houses, there are about 20 banks in all. Pop. 644,405.

**Calcutta**, the capital of Bengal, and seat of the supreme government in India, is situated in lat. 22° 34' N. and lon. 88° 17' E., on the east side of the Hoogly, one of the branches of the Ganges, about 100 miles from the sea. It extends nearly 4 miles along the river, with an average breadth of 1½ miles. The northern quarter, or the Black Town, inhabited by the native population, consists of narrow, dirty, unpaved streets, chiefly of mud hovels; the whole deep, black, and dingy, and offering a complete contrast to the front parts possessed by Europeans. These last generally present handsome detached brick houses, which, being stuccoed, have so elegant an appearance that Calcutta is sometimes called "the City of Palaces" and "the Indian Corinth." The stupendous fortification of Fort William is situated about one fourth of a mile below the town; and the intervening space, called the Esplanade, contains the magnificent residence of the governor-general. Adjoining the esplanade and the river-bank of the city is the "Strand,"—a quay extending between 2 and 3 miles, and contiguous to which there is anchorage for ships of 600 tons; while Diamond Harbor, about 30 miles below, is sufficiently deep for the largest vessels. The access to the port is intricate, owing to shifting banks of sand and mud; but this disadvantage is outweighed by its ready intercourse, through the Ganges and its tributaries, with the richest and most populous regions of Hindostan, and which, joined to its being the place of chief resort of civil and military functionaries, has rendered Calcutta the principal commercial emporium of the East. Proposals have been made from time to time to remove the seat of the supreme government from Calcutta. Its unhealthiness, especially in the rainy season, its remoteness from the centre of Hindostan, and its distance from England, have each been animadverted upon. These disadvantages of Calcutta have now, however, been almost entirely removed, or their consequences have been mitigated by the conquests of science and modern engineering. The railway and the telegraph have brought the viceroy at Calcutta into close contact with every corner of India; while an ample water supply, improved drain-

age, and other sanitary reforms have rendered Calcutta the healthiest city in the East,—healthier, indeed, than some of the great European towns. English civilization has thus enabled Calcutta to remain the political capital of India. The same agency still secures the city in her monopoly of the sea-borne trade of Bengal. The river Hoogley, or Hugli, has long ceased to be the main channel of the Ganges; but Calcutta alone of all the successive river capitals of Bengal has overcome the difficulties incident to its position as a deltaic centre of commerce. Strenuous efforts of engineering are required to keep open the "Nadiya Rivers," namely, the three offshoots of the Ganges which combine to form the Hoogley. Still greater watchfulness and more extensive operations are demanded by the Hoogley itself below Calcutta, to save it from the fate of other deltaic streams, and prevent it from gradually silting up. In 1853 the deterioration of the Hoogley channel led to a proposal to found an auxiliary port to Calcutta on the Matlah, another mouth of the Ganges. A committee, then appointed to inquire into the subject, reported that "the river Hoogley was deteriorating gradually and progressively." At that time "science had done nothing to aid in facilities for navigation," but since then everything has been done which the foresight of modern knowledge could suggest, or the power of modern capital could achieve. Observations on the condition of the river are taken almost hourly, gigantic steam-dredgers are continually at work, and the shifting of the shoals is carefully recorded. By these means the port of Calcutta has been kept open for ships of the largest tonnage, and now seems to have outlived the danger which threatened it. The small number of English resident in Calcutta (where, however, they are far more numerous than in any other part of India) may well excite surprise. It was supposed that the cessation of the Company's monopoly, and of the prohibition of European resort to India, would occasion an influx of British settlers and capital; but this anticipation has not been realized. Scarcely a single English agriculturist, with capital sufficient to cultivate 100 acres of land, has established himself in India, except for the cultivation of indigo and tea, and there has been no immigration of artisans. And this, after all, is only what might have been expected; the country being too fully occupied, the burden on the lands too heavy, and the wages of labor far too low, to admit of anything like an extensive European immigration. The Eurasians, the progeny of white fathers and native mothers, are mostly employed as clerks in the government offices and mercantile establishments, and are said to be an industrious and useful class. The principal merchants and traders consist of British and other Europeans, Portuguese born in India, Armenians, Jews, Persians from the coast of the Persian Gulf (commonly called Parsees), Moguls, Mohammedans of Hindostan, and Hindoos; the latter usually either of the Brahminical or mercantile castes, and natives of Bengal.

The principal foreign business is conducted by English merchants; but other parties also, either in partnership with the English or on their own account, speculate largely to Europe, America, and especially to China. The brokers known under the name of Sircars and Baboos are all Hindoos.

The port of Calcutta extends 10 m. along the Hoogley, with an average width of working channel of 250 yards, and with moorings for 160 vessels. The navigation of the river from the Sand Heads to Calcutta, a distance of about 130 m., is naturally dangerous and intricate; but rendered comparatively safe by a skilful and excellent, though costly, pilot establishment. In 1873, 2,231 vessels, with an aggregate tonnage of 2,672,618 tons, cleared the port of Calcutta. — *Banks.* The Bank of Bengal was established in 1809. Its authorized capital is 31,000,000 rupees, which, at 2s. the rupee, gives £3,000,000 or \$15,000,000. The shares are selling at a high premium. The management is conducted by nine directors,—three appointed by government, and six elected by proprietors; time of service for the latter, three years. This bank possesses peculiar advantages, and consequently its circulation extends over a very large area, its notes being received at all public offices, in payment of revenue, by the collectors of the various districts. Besides this (exclusive of savings-banks) there are 26 other banks, or branches of banks, of which 17 are "limited." The nominal capital of these amounts in the aggregate is about £16,000,000, the paid up capital, however, falling much short of this amount. Pop. (including suburbs), 822,429.

*Madras*, the principal emporium of the coast of Coromandel, or western shore of the Bay of Bengal, lat. of lighthouse 13° 5' 10" N., lon. 80° 16' 29" E. It is the seat of the government of the second presidency of British India, having under it a territory, including the tributary states, of 257,042 square miles, with a population, according to the latest returns, of 36,060,551, paying in 1865 a gross annual revenue of about £7,000,000 sterling. The town had a population, in 1862, of 457,771, and is situated in the Carnatic province, a low, sandy, and rather sterile country. It is without port or harbor, lying close upon the margin of an open roadstead, the shores of which are constantly beaten by a heavy surf. Besides these disadvantages, a rapid current runs along the coast; and it is within the sphere of the hurricanes or typhoons, by which it is occasionally visited. In every respect, indeed, it is a very inconvenient place for trade, and its commerce is consequently

greatly inferior to that of either Calcutta or Bombay; the value of imports for the year 1878 being only \$19,497,165; and of exports, \$35,039,370. — In Madras roads large ships moor in from 7 to 9 fathoms, with the flag-staff off the fort bearing W. N. W., 2 m. from shore. From October to January is generally considered the most unsafe season of the year, in consequence of the prevalence of storms and typhoons. On October 15 the flag-staff is struck, and not erected again until December 15, during which period a ship coming into the roads, or, indeed, anywhere within soundings on the coast of Coromandel (reckoned from Point Palmyras to Ceylon), violates her insurance, according to the conditions of the policies of all insurance offices in India. The cargo boats used for crossing the surf, called *Massula* boats, are large and light, made of very thin planks sewed together, with straw in the seams instead of calking. Pop. 397,552.

**India-Cottons**, a name applied, in upholstery trade, to a heavy kind of figured chintz.

**India-Gum**, an inferior kind of gum-arabic imported from Bombay and Calcutta.

**India-Ink**, or *China-Ink*. See *INK*.

**India Matting**, grass or reed mats, made in the East from *Papyrus corymbosus*, large quantities of which are exported.

**Indiana**, one of the States of the American Union, is bounded E. by the State of Ohio, S. by the river Ohio, which separates it from Kentucky, W. by Illinois, from which it is partly separated by the Wabash River, and N. by Michigan and Lake Michigan. It lies between lat. 37° 51' and 40° 46' N., and lon. 85° 49' and 88° 2' W. Extreme length from N. to S., 276 m.; greatest breadth, 175 m. Area, 33,809 sq. m. It is divided into 92 counties. *Indianapolis*, the capital and largest city of Indiana, is situated near the centre of the State, on the W. fork of White River, 100 m. N. W. of Cincinnati, in the middle of a fertile plain, and in the vicinity of an extensive coal-field. Its manufactures are varied and important, and its commerce very extensive. Ten lines of railroads centring there connect the city with all parts of the State and with the principal cities of the West. The population of Indianapolis, which was only 2,692 in 1840, numbers now about 80,000. The most important cities of Indiana, besides Indianapolis, are: Evansville, with a population of about 30,000; Fort Wayne, 25,000; Jeffersonville, 10,000; Lafayette, 16,000; La Porte, 8,000; Logansport, 11,000; Madison, 13,000; New Albany, 18,000; Richmond, 11,000; Bend, 9,000; Terre Haute, 20,000; Vincennes, 7,000. Total population of the State, about 2,000,000.

Indiana may be generally characterized as a great plain, inclining towards the S. W. A range of hills extends along the Ohio from the mouth of the Great Miami to Blue River, and the shore of Lake Michigan is lined by large sandy hills, which rise to a height of 200 feet. In some other parts are to be found "knobs," but these are seldom of great extent or elevation. The surface of the country naturally divides itself into several extensive river valleys. The valley of the Ohio, comprising an area of about 6,500 sq. m., is a limestone tract, and was originally covered with forests. About one third of it is rugged and broken, so as to be unfit for cultivation. The White River Valley, extending through the centre of the State, from the Wabash to the Ohio, contains about 9,000 sq. m. This district is almost uniformly level, and richly wooded, except in the W., where there are some ranges of low, rugged hills, and several patches of prairie ground. The soil is of the richest kind. The Wabash Valley is much larger than the others, and contains upwards of 12,000 sq. m. The eastern portion equals the White River Valley in fertility, but the other parts are not so productive. The N. part of the State, watered by the St. Joseph and the Kankakee Rivers, is somewhat more swampy than the Wabash Valley; and a large tract, comprising the sand-hills on Lake Michigan, is covered only with stunted pines and burr oaks. The State is well watered by numerous beautiful streams and rivers, but, with the exception of the Ohio and Wabash, few of them are navigable. The Wabash is the largest river that has its course mainly within the State, and, together with its branches, drains three fourths of the entire surface. It rises in the W. of Ohio, and flows first in a N. W. direction, and then S. W. till it meets the boundary of Illinois, which it follows southward for more than 100 m., till it falls into the Ohio, after a course of upwards of

500 m.: for 400 of which it is navigable for steamboats at high water. The Ohio forms the entire S. boundary of the State. The other principal rivers of Indiana are tributaries of the Wabash. The White River, the most important of these, is formed by the West and East Forks, — two rivers, respectively about 300 and 200 m. long, — which unite about 100 m. above its confluence with the Wabash. The Miami is formed by the St. Joseph and St. Mary in the N. E., and falls into the Ohio. The Upper St. Joseph, with its tributaries, passes through the northern counties, and falls into Lake Michigan. Indiana resembles the other Western States N. of the Ohio in climate. They are generally milder than those on the Atlantic coasts, but very subject to sudden changes. The winter is very severe in the N. parts, but more genial in the S. Except in the neighborhood of wet prairies and swamps, the climate is everywhere healthy. Indiana possesses all the elements of extraordinary fertility. The richest soil is that of the river bottoms, where it is very deep and exceedingly fertile. The most productive are those enclosed by the river hills, which run parallel to the Ohio and other rivers. The

Fig. 285. — SEAL OF INDIANA.

extensive valley of the Wabash is a tract of this description. Behind the river hills, a table-land spreads out, forming what may be called the interior of the country, and here, instead of the bottom-lands, or river valleys, there are vast prairies. The soil of these is not so luxuriant, but is such as amply to repay the expense of culture. Even the wet and marshy parts of the State admit of being brought under cultivation. Indiana produces large quantities of Indian corn, wheat, oats, and Irish potatoes, as well as a fair proportion of the other productions common to the Western States. The relative value of agricultural products for the year 1878 is given in this work under the names of each of the principal crops.

The number of farms in Indiana under cultivation, as reported by the last census, was 161,289, and the extent of improved land was 10,104,279 acres, 7,189,234 of woodland, and \$26,035 of other unimproved land. The value of the farms returned was \$634,804,189; of farming implements and machinery, \$17,676,591. The orchard produce was estimated at \$2,858,086, and market-garden products, \$486,777; of forest products, \$2,645,679. — The chief minerals of Indiana are coal, iron, lime, marble, freestone, and some copper. Of these the first is by far the most important. The coal-beds of Indiana, which form part of the great coal-field which extends through Illinois, Indiana, and Kentucky, cover an area of about 6,500 sq. m., in the S. W. part of the State, and extend from Warren Co. in the N. to the Ohio River on the S., a distance of about 150 m. They consist of three varieties of bituminous coal: caking coal, not-caking or block coal, and canal coal. In 1879 there were about 60 mines in operation, whose daily production was about 600,000 tons. The quality of the coal, and its vicinity to available iron-ore beds, give to Indiana marked advantages for the manufacture of iron and steel. — Indiana has no direct foreign commerce, but it has a considerable transit trade, owing to its magnificent systems of canals and railroads. It exports large quantities of agricultural produce, agricultural implements, etc., and has a considerable trade in pork-packing; the hogs packed in this State, chiefly at Indianapolis, for the year 1878, numbering 496,025. — The principal canals are the Wabash and Erie Canal, between Evansville on the Ohio and Toledo on Lake Erie, 467 m., of which 379 m. are in Indiana; and the White Water Canal, 63 m. long, uniting Lawrenceburg on the Ohio with Hagerstown. In 1879 the State had 4,198 m. of railroad. The following table shows the names of the companies, the total length of roads, and the total length in Indiana: —

Companies.	Total length of line.	Total length of line in Indiana.
Anderson, Lebanon, and St. Louis .....	miles. 19.39	miles. 19.39
Baltimore and Ohio and Chicago .....	262.60	146.35

White Water .....	62.05	62.05

In 1879 Indiana had 94 national banks in operation, whose paid-in capital was \$15,626,530. There were, besides, 150 state banks, saving-banks, and private bankers, whose aggregate capital was \$5,081,175. The State debt amounted to \$4,888,178, of which \$3,904,783 consisted of bonds held by the school fund. The total value of taxable property was \$550,616,387.

## Indianapolis. See INDIANA.

**Indianapolis, Bloomington, and Western R.R.** runs from Indianapolis, Ind., to Pekin, Ill., 202.3 m., with extension from Champaign to Havana, Ill., 100.7 m., and branch from White Heath to Decatur, Ill., 30.9 m.; total length, 333.9 m. This Co., whose offices are in Indianapolis, was formed in 1869 by the consolidation of the Indianapolis, Crawfordsville, and Danville, and the Danville, Urbana, Bloomington, and Pekin R.R. The main line was opened the same year. In 1874 the Co. defaulted on the interest on its bonds due in Oct. of that year, and the road was placed in the hands of a receiver, by whom it has since been operated. *Financial statement:* Cap. stock, \$7,610,000; funded debt, \$9,785,000, as follows: 1st mortgage Danville, Urbana, Bloomington, and Pekin R.R., issued 1869, \$2,000,000, payable 1909, interest 7 % (April and Oct.); 1st mortgage Indianapolis, Bloomington, and Western R.R., issued 1869, \$3,000,000, payable 1909, interest 7 % (April and Oct.); 2d mortgage (same lines), issued 1870, \$1,500,000, payable 1890, interest 8 % (Jan. and July); 1st mort-

gage (same lines), extension, issued 1872, \$3,285,000, payable 1912, interest 7% (Jan. and July). The \$2,000,000 1st mortgage bonds of the Danville, Urbana, Bloomington, and Pekin R.R., issued prior to consolidation, were intended to be exchanged for the 1st mortgage bonds of the consolidated roads, amounting to \$5,000,000, of which but \$3,000,000 have been issued, the remainder being held in trust for exchange. The sale of the extension road, which was effected in 1879, will modify the above statement.

**Indianapolis, Cincinnati, and Lafayette R.R.** runs from Lafayette, Ind., to Ohio State line, 158.5 m., with branch from Greensburg to Stone Quarries, 5.5 m., and the Hardentown Cut-off 2.5 m. In 1866 the Co. leased in perpetuity the Cincinnati and Indiana R.R., which runs from Cincinnati to the Indiana State line, 20.5 m., and in 1876 the Harrison branch from Valley Junction, O., to Harrison, O., 7.5 m., making a total of 194.5 m. operated. This Co., whose offices are in Cincinnati, O., was formed in 1866 by the consolidation of the Indianapolis and Cincinnati, and the Lafayette and Indianapolis R.R. Cos. The road has been in the hands of a receiver since 1876. *Financial statement:* Cap. stock, common, \$5,587,150; preferred, \$1,419,300; Cincinnati and Indiana R.R. stock, \$18,000; funded debt, \$3,593,300; unpaid coupons, \$1,204,709.27. Funded debt in detail: 1st mortgage (Indianapolis and Cincinnati), issued 1858, \$1,600,000, payable 1888, interest 7% (April and Oct.); 1st mortgage (Cincinnati and Indiana), issued 1862, \$499,000, payable 1892, interest 7% (June and Dec.); 2d mortgage (Cincinnati and Indiana), issued 1867, \$1,497,000, payable from 1877 to 1882, interest 7% (Jan. and July); 2d mortgage (Indianapolis, Cincinnati, and Lafayette), issued 1867, \$2,800,000, payable 1897, interest 7% (Feb. and Aug.); equipment mortgage, issued 1873, \$344,000, payable 1883, interest 10% (March and Sept.); funded coupons (bonds of 1867), issued 1873, \$125,550, payable 1878, interest 7% (March and Sept.); 3d mortgage (joint bonds), issued 1869, payable 1899, interest 7% (June and Dec.); funded coupons (bonds of 1869), issued 1873, \$320,750, payable 1883, interest 7% (March and Sept.); unpaid coupons on 3d mortgage and funded coupon bonds, \$371,841. The Co. guarantee one half of \$525,000 mortgage 6% bonds of the Street Connection R.R. in Cincinnati, issued by the Cincinnati and Indiana and the Little Miami R.R. jointly. There are two issues of these bonds, one in 1864 for \$250,000, and the other in 1868 for \$275,000, both payable in 30 years from date.

**Indianapolis, Decatur, and Springfield R.R.** runs from Decatur, Ill., to Guion, Ind., 101.25 m., and is to be continued to Indianapolis. This Co., whose offices are in Tuscola, Ill., was formed in 1863 by the consolidation of two Cos., chartered in Indiana and Illinois under the name of the Indiana and Illinois Central R.R. Co., and which was sold under foreclosure in 1875. It is shortly to be continued to Indianapolis. *Financial statement, 1878:* Cap. stock, \$500,000; funded debt, \$2,943,000, as follows,—1st mortgage 30-year bonds, issued 1876, \$274,000, interest 7%; and 2d mortgage income 30-year bonds, issued 1876, \$2,669,000, interest 7%. The issue of 1st mortgage bonds is limited to \$1,800,000. The 2d mortgage bonds represent the old 1st mortgage bonds.

**Indianapolis, Peru, and Chicago R.R.** runs from Indianapolis, Ind., to Peru, Ind., 72.87 m. This Co., whose offices are in Indianapolis, was

first chartered in 1852 as the Peru and Indianapolis R.R. The road was opened in 1856, and the Co. reorganized under present title in 1876; it has issued no financial reports.

**Indianapolis and St. Louis R.R.** runs from Indianapolis, Ind., to Terre Haute, Ind., 71.84 m. This Co., whose offices are in Indianapolis, has leased the St. Louis, Alton, and Terre Haute R.R., 189 m., and its Alton Branch, 4.2 m., for a term of 90 years from 1867 at an annual rental of \$450,000. It operates also the Carbon and Otter Creek Valley R.R., 1.6 m., specially used for carrying coal. *Financial statement:* Cap. stock, \$600,000; funded debt, \$3,500,000, as follows,—1st mortgage bonds, issued 1869, \$2,000,000, payable 1919, interest 7% (no fixed time); 2d mortgage bonds, issued 1870, \$1,000,000, payable 1900, interest 7% (April and Oct.); equipment bonds, issued 1871, \$500,000, payable 1881, interest 8% (Jan. and July).

**Indianapolis and Vincennes R.R.** runs from Indianapolis, Ind., to Vincennes, Ind., 116.63 m. This Co., whose offices are in Pittsburgh, Pa., was organized in 1867, and the road opened in 1869. It is operated by the Pennsylvania Co., which possesses all its capital stock. *Financial statement:* Cap. stock, \$1,402,000; funded debt, \$3,150,000, as follows: 1st mortgage 7% bonds, \$1,700,000, payable 1908, and 6% bonds, \$1,450,000, payable 1900.

**Indian Hemp.** See HEMP.

**Indian Oak**, a name sometimes applied to the teak-wood, *Tectona grandis*.

**Indian Ocean**, a vast oceanic basin, separated from the Pacific on the E. by the Eastern Archipelago and Australia, bounded on the S. by a line drawn from the Cape of Good Hope to Bass' Strait, divided from the Atlantic by Africa on the W., and enclosed by the countries of Asia on the N. It communicates with the Chinese Sea by the Strait of Malacca, Sunda Strait, and the Strait of Flores. Principal inlets, the Bay of Bengal, the Sea of Oman, the Persian Gulf, and the Red Sea. Chief straits, the Channel of Mozambique and Palk's Strait. The most important islands are Madagascar, Mauritius, Bourbon, the Comoro Islands, Seychelles, and Socotra, belonging to Africa; the Laccadives, Maldives, Ceylon, the Andaman and Nicobar Islands, to Asia. Its principal affluents are, in Asia, the Saluen, Irrawaddy, Brahmaputra, Ganges, Godavery, Kistna, Nerbuddah, Indus, and the Shat-el-Arab, formed by the junction of the Tigris and Euphrates; in Africa, the Zambeze. The chief seaports are, Calcutta and Bombay in India; Malacca, in the Eastern Archipelago; Aden, Mocha, and Muscat, in Arabia; Zanzibar, etc., in Africa. The monsoons, or periodical winds, prevail in the N. part of the ocean, blowing from the S. W. between April and October, and S. E. from October to April. Tempests are general at the periods of change, and between lat. 5° and 40° S. violent hurricanes frequently occur.

**Indian-Red**, a pigment obtained from a kind of red ochre, and producing purplish russet tints. It is brought from the East in the form of small lumps, and sometimes as a coarse, gritty powder. *Imp. duty*, 25 per cent.

**Indian-Shot.** See CANNA.

**Indian-Yellow**, a dye of questionable origin, said to be procured from the urine of the cow, after eating decayed and yellow mango-leaves; other authorities refer it to camels' dung. Analysis shows it to be composed chiefly of purreic acid, combined with magnesia. Its name, in some parts of the East, is Purree.

**India-Rubber, Caoutchouc, Elastic Gum,** the concrete juice of several tropical trees of both hemispheres, more particularly of *Siphonia elastica* (of South America), and *Ficus elastica* (of India). Immense quantities of *I.-R.* come from the Brazilian province of Pará, and from the U. States of Colombia. In order to obtain this substance, the natives of the valley of the Amazon make a longitudinal gash in the bark of the tree with a narrow hatchet; a thick, white, and oily liquid (a sort of vegetable milk) flows out, a wedge of wood is inserted to keep the gash open, and a small clay cup is stuck to the tree beneath the gash. In four or five hours the milk ceases to run, and each wound has yielded from three to five table-spoonfuls. The "seringero," or *I.-R.* gatherer, then empties the contents of the cups into an earthen vessel and commences the operation of forming it into shapes and smoking it. This must be done at once, as the milk soon coagulates. A fire is made on the ground, of nuts of the wassou-palm tree, over which is placed, inverted, an earthen pot with a hole in the bottom whence issues a jet of pungent smoke. Moulds are made either of clay or wood, which are dipped into the milk, and then passed slowly through the hot smoke. When the required thickness is obtained, the moulds are cut or washed out. Smoking changes the color of the rubber very little, but by exposure to the sun and atmosphere it becomes brown, and in time black. The superiority of the *I.-R.* imported from the valley of the Amazon is said to be owing to the peculiar properties of the smoke of this nut, no other smoke producing a similar effect upon the gum. A belt of forest trees extends 10 degrees each side of the equator which yield *I.-R.* of various kinds; so the supply is literally inexhaustible. The gum from India and the Pacific coast of South America is obtained by allowing the sap to flow down the side of the tree, and is then gathered with the loose bark and dirt into *ceroons* or bundles for shipment. — The general properties of *I.-R.*, as well as its numerous applications, are well known. The fresh juice has a cream-like appearance and consistence, is coagulated by heat, and is miscible with water, alcohol, and wood-naphtha; sp. gr. 1.012 to 1.041; it yields from 18% to 45% of solid *I.-R.*, either by heat or evaporation. By excluding it from the air it may be preserved unchanged for a considerable period. Solid *I.-R.* has a sp. gr. ranging between .919 and .941; it melts at 248° F. into a viscid mass, which does not again harden on cooling; it is unaltered by chlorine, hydrochloric acid, sulphurous acid, fluosilicic acid, ammonia, caustic alkaline lyes (even when boiling), and most similar substances; nitric acid and sulphuric acid act on it only by long contact when concentrated. Some specimens of *I.-R.* are harder than gutta-percha itself, and equally inelastic, whilst others never perfectly solidify, but remain in a condition resembling that of bird-lime or printer's varnish.

Up to 1820 *I.-R.* was used only for effacing pencil-marks, and about that time a piece half an inch square sold for 60 cents. But the extreme elasticity and extensibility of this singular substance was attracting the attention of practical men both in Europe and America. One of the earliest patents obtained for applications of caoutchouc was taken out in England by Mr. Thomas Hancock, of Newington, in 1820, for the use of *I.-R.* for the wrists of gloves, for braces, for garters, for boots and shoes instead of laces, and for other similar purposes. The rings for the wrists of gloves, etc. were simply cut from the bottle *I.-R.* by machinery the patentee himself contrived for that purpose. Mr. Hancock soon noticed and utilized the fact that two clean freshly cut surfaces of *I.-R.*, when pressed together, cohere and unite perfectly. This further led him to devising a machine by which all the waste cuttings and par-

ings might be worked up. This machine consisted of a cylinder revolving within a cover, both being provided with steel teeth, by which the pieces of *I.-R.* placed between them were torn into shreds, and then kneaded into a solid coherent mass of homogeneous texture. The first machine of this kind would work up about 1 lb. of *I.-R.*, but now machines on the same principle are in use operating on more than 200 lbs. of material at once, and turning it out on a roll 6 ft. long and 10 in. or 12 in. in diameter. While Hancock was thus successful in mechanically working *I.-R.*, Macintosh, of Glasgow, found means of effecting its solution by coal-naphtha, and he obtained, in 1823, a patent for the application of his discovery to the fabrication of waterproof garments. Waterproof cloth is prepared by varnishing one side of a suitable fabric with a solution of *I.-R.*, or by covering one side of the cloth with a thin film, and then bringing it into contact with a second piece similarly prepared, the two *I.-R.* layers becoming incorporated when the double cloth is passed between rollers. Other solvents for *I.-R.* have been discovered in ether, chloroform, sulphide of carbon, and rectified turpentine. By treatment with these liquids it swells up, and eventually dissolves, producing a viscid,ropy mass, which, by evaporation of the solvent, leaves the *I.-R.* with all its original elasticity. By the use of these last-named solvents, the persistent and disagreeable odor occasioned by coal-oil is avoided. — It will now be observed that there are two distinct modes of working *I.-R.*: by dealing with the solid material, or with the solution. Thus, from a solid disk of *I.-R.* long ribbons of the material may be cut, and these ribbons, by being passed between a set of circular knives, may be divided into a number of square threads. These threads may then be drawn out to 6 or 10 times their length; and, if wound and maintained in this state of tension for 48 hours in a warm place, they will lose their condition of tension, and their elongated form will become their natural and unstrained one. In this manner are the *I.-R.* threads prepared, which, covered with silk or other material, form elastic fabrics, such as those used in the sides of boots. The circumstance of *I.-R.*, when heated for some hours at a temperature a little above the boiling-point of water, retaining whatever form it has during the heating, is the basis of obtaining thin sheets and other forms of the material. Tubes are made by forcing the heated *I.-R.* through an annular opening by application of great pressure; it sets in cooling, preserving a section corresponding with the orifice through which it issues. In another mode of forming tubes, a paste composed of *I.-R.*, oxide of zinc, and lime is formed into sheets, which are cut into strips. The strips are folded longitudinally, and the edges are cut together at an angle of 45° with the surface, so that the cut surfaces may meet each other when the strip is rolled on a mandril to give it a cylindrical form. A slight pressure suffices to solder together the cut surfaces, and the tube is then "vulcanized" by a process to be presently described. The dissolved *I.-R.* serves to prepare waterproof garments, round threads, sheets of *I.-R.*, etc. Fabrics are coated with the solution by pouring it on the material as it is passing horizontally from a roller. A straight-edge, under which the charged cloth passes, distributes the *I.-R.* in a uniform layer, the thickness of which is regulated by the space between the knife-edge and the fabric. When sulphide of carbon is the solvent used, its evaporation is complete in about 10 minutes, but with other solvents two or three hours are required. The *I.-R.* is usually mixed with lampblack before being spread on the cloth, and the article is finished by giving the *I.-R.* layer a coat of gum-lac varnish. Sheets of *I.-R.* are obtained by spreading 15 or 20 layers over a cloth, which is afterwards detached by wetting it with a solvent. — Threads of circular section are manufactured from a paste of *I.-R.* made by dissolving that substance in sulphide of carbon mixed with 8 per cent of alcohol. This paste is placed in a cylinder, out of which it is forced by a piston through a number of circular holes, whence it issues in the form of filaments. These are received upon a stretched cloth, which moves along, carrying the parallel threads, until the sulphide of carbon has evaporated. — A modification of *I.-R.*, possessing very valuable qualities for many purposes, was patented in 1839 by Charles Goodyear of New Haven, Conn., and largely applied by him to the fabrication of waterproof boots. In 1842 these boots were imported into Europe, and it was seen that this form of the material had the advantages of not sticking to other bodies at any ordinary temperatures, and of preserving its elasticity even in the coldest weather, whereas ordinary *I.-R.* becomes rigid by cold. The cut edges of this variety of *I.-R.* do not cohere by pressure. Mr. Goodyear attempted to keep his process a secret; but Mr. Hancock, having soon detected the presence of sulphur in the American preparations, set to work to discover how that substance was made to combine with the *I.-R.* He succeeded, and he obtained a patent for sulphurizing *I.-R.* before the original inventor had applied for one. Mr. Hancock found that a sheet of *I.-R.* immersed in melted sulphur at 250° F. gradually absorbed from 12 to 15 per cent of its weight of sulphur; and, further, that this does not in any way alter its properties. When, however, the sulphurated substance was for a few minutes exposed to a temperature of 300°, it acquired new qualities, which were precisely those of the modification employed by Mr. Goodyear for his impervious

boots. This transformation effected by sulphur Mr. Hancock called *vulcanization*; and *vulcanized I.-R.* is now employed in nearly all the innumerable applications of *I.-R.*, provided the presence of sulphur is not absolutely objectionable. Good-year's process consists in mixing the sulphur with the *I.-R.*, the suitable proportion (7 to 10 per cent) having been determined beforehand, and the sulphur ground up with the *I.-R.* in the masticating machine, or disseminated through the viscous liquid if a solution is used, or dissolved in the solvent employed. This gives better results than Hancock's process, because the sulphurization is more uniform, and this method is, therefore, more largely employed. When the various articles have been fabricated in the ordinary manner from the mixture of *I.-R.* and sulphur, they are enclosed in vessels, where they are submitted for two or three hours to the action of steam under a pressure of nearly 4 atmospheres, so that the steam may have a temperature of about 290° F. A still easier method consists in steeping the articles (which in this case should be thin) in a solution of one part of chloride of sulphur in 60 of bisulphide of carbon. The object becomes vulcanized by simple exposure to the air, without the aid of heat. But this process is said to be liable to cause the article afterwards to become brittle. The addition of oxide of zinc, carbonate of lead, and other substances is found to yield a product better adapted for certain purposes than one in which only sulphur is used.

Among the many applications of vulcanized *I.-R.* those connected with its elasticity and its enormous contractile power when extended are particularly striking. Under Mr. E. Smith's patent, torsion springs for roller blinds, door springs, clock springs, carriage springs, etc., are made of it. Mr. Hodges, in another patent, has availed himself of the same property as a new mechanical power. Short lengths of *I.-R.*, which he terms "vulcanized power purchases," are successively drawn down from or lifted to a fixed bearing, and attached to any weight which it is required to raise; when a sufficient number of these power purchases are fixed to the weight, their combined elastic force lifts it from the ground. Thus, 10 purchases of the elastic strength each of 50 lbs. raise 500 lbs. Each purchase is 6 inches long, and contains about 1½ oz. of vulcanized caoutchouc. These 10 purchases, if stretched to the limit of their elasticity (not of their cohesive strength), will lift a weight exceeding 650 lbs. The same principle has been applied to relieve and equalize the strain on ships' cables, especially where several boats are towing one vessel; and as a projectile force. A number of power purchases, attached to the barrel of a gun constructed to project harpoons, will exert a power, if suddenly relieved, proportioned to their aggregate forces. By similar contrivances balls may be projected 200 yards or more, and a charge of No. 4 shot can be thrown 120 yards. A bow, in which the string alone is elastic (the reverse of the usual form), has been contrived which throws a 30-inch arrow 170 yards.

There are several patents for making artificial *I.-R.*, the best of which is a compound of chloride of sulphur, oil, and collodion. In its plastic state it is easily moulded, and hard and durable when well set. It can be made of any color, and is susceptible of a high polish.

The list of applications of vulcanized *I.-R.* would be a very long one; but as a great number of these applications must be known to everybody, it will be unnecessary to specify them. Its employment in the construction of portable boats, pontoons, life-buoys, dresses for divers and for the preservation of life at sea, air-tight bags and cushions, air and water beds, cushions of billiard-tables, surgical implements, stereotype pages for printing, carriage springs, belts, hose, are a few of the thousand instances of its utility which might be quoted.

The last great improvement in the manufacture of *I.-R.* is the discovery that by continuing the process of vulcanization for a longer time at an increased heat and under pressure, a hard black substance is obtained, which can be turned in a lathe like ebony. This substance is now applied to an extraordinary number of uses. See *VULCANITE*.

The first company organized in the U. States to manufacture *I.-R.* into waterproof clothing was the Roxbury India-Rubber Company, established at Roxbury, Mass., by Mr. Edwin M. Chaffee, and chartered in 1833. This important industry has since been largely developed in this country, where *I.-R.* is manufactured in a great variety of articles and on a large scale, principally in New York and in the New England States. For the year 1878 our imports of *I.-R.* and gutta-percha amounted to 12,512,203 lbs., valued at \$4,711,102; which came chiefly from Brazil (\$2,457,398), the U. States of Colombia (\$1,006,521), and India, mostly through England (\$884,711). Manufactured goods to the value of \$242,564 were also imported, mostly from England. For the same year the exports of boots and shoes and other *I.-R.* manufactures amounted to \$305,707.

*Imp. duty:* crude *I.-R.* or milk of *I.-R.*, free; raw, or unmanufactured (bottles, slabs, and sheets), free. — Manufactures of *I.-R.*, mixed with silk or other material, 45 per cent. — Boots and shoes, 30 per cent. — Braces, suspenders, webbing, or other fabrics, wholly or part of *I.-R.*, n. o. p. f., 35 per cent. — Articles wholly of *I.-R.*, n. o. p. f., 25 per cent.

**Indicator**, an index machine for various pur-

poses; a water-gauge in a steam-engine; the dial and mechanism of a dial telegraph, etc.

**Indigo**, a blue dyestuff extracted from several leguminous plants indigenous to the tropical regions of Asia, Africa, and America, especially from *Indigofera tinctoria* and *I. anil*, which are naturalized in the Southern States, and were formerly cultivated in S. Carolina and Florida. It exists in the plant as a colorless juice. The method of manufacture consists in steeping the plant in water until fermentation sets in; the coloring matter dissolves in the water, forming a yellow solution, which is drawn off from the rest of the vegetable matter, and agitated and beaten to bring it freely into contact with the air for about 2 hours; this treatment causes the *I.* to form and settle down as a blue precipitate; this is cut, while soft, into cubical cakes, and dried by artificial heat. To hasten the formation of the *I.*, a little lime-water is sometimes added to the yellow solution. The *I.* of commerce contains *Indigo-blue* or *Indigotine*, its most important constituent, *Indigo-red*, and many other substances, some of which must be regarded as accidental impurities or adulterations. *I.* is tasteless; scentless; of an intense blue color, passing into purple; when rubbed with a smooth hard body, it assumes a coppery hue. It is insoluble in water, cold alcohol, ether, alkalies, hydrochloric acid, dilute sulphuric acid, and the cold fixed and volatile oils; slightly soluble in boiling alcohol and oils; freely soluble in concentrated sulphuric acid, and, when decolorized or reduced by contact with deoxidizing substances, in alkaline lyes. Its color is destroyed by chromic acid, nitric acid, and chlorine; when suddenly heated, it gives off rich purple fumes, which condense into brilliant copper-colored needles. The best *I.* is that which has the deepest purple color, that assumes the brightest coppery hue when rubbed with the nail; its fracture is homogeneous, compact, fine-grained, and coppery; its powder is of an intensely deep blue tint, and light enough to swim on water; and it leaves only a fine streak when rubbed upon a piece of white paper. In general, when *I.* is in hard, dry lumps of a dark color it is considered of bad or inferior quality. *I.*, when in hard or brittle lumps, or in dust or small bits, is often adulterated with sand, pulverized slate, and other earthy substances. For its properties and use in dyeing, see *DYEING (BLUE COLORS)*.

*I.*, imported from the several parts of British India, Java, and Manilla, differs much in quality and in shades of color. The best Bengal *I.* is shipped from Calcutta in cubical cakes of a light blue color, and possesses all the qualities above enumerated. Other qualities are of shades of violet, red, and copper-color. The African *I.*, from Egypt and Senegal, are of finer blue shades, but generally contaminated with earthy matters. The best American qualities, as some of those from the U. States of Colombia, are equal to the best Bengal. The consumption of late years has not increased in a ratio corresponding to the increase of population and the expansion of manufactures, — a circumstance which seems attributable to the decreasing use of blue cloth, in the dyeing of which it is principally used, and perhaps also to the introduction of substitutes suggested by the advanced state of chemical knowledge. The American *I.* is generally enclosed in sacks of coarse linen sewed into an ox-hide, a kind of package which is called a *seron*, and contains usually about 250 lbs. The East Indian *I.* is in chests of about 3½ factory maunds, or 260 lbs. The imports into the U. States for the year 1878 amounted to 1,831,494 lbs., valued at \$1,537,680, which came mostly from the East Indies (1,343,343 lbs., valued at \$1,164,599), and from the U. States of Colombia (341,327 lbs., valued at \$303,868).

*Imp. duty:* Indigo, free; carmined, 20 per cent; paste, 10 per cent; extracts, 10 per cent.

**Indigo-Blue**, the pure blue principle of indigo, also called *indigotine*. — The tint or color produced by the indigo dye. — A preparation of indigo,

usually in small lumps, for the use of the laundry.

**Indigo-Purple**, a coloring matter consisting of interlaced silky crystals having a coppery lustre, obtained by filtration from a solution of indigo in forming sulphuric acid, when largely diluted with water.

**Indigo-White**, a grayish-white mass of minute crystals, generally light blue on the surface, and rapidly turning blue on exposure to the air; soluble in alkalies, alcohol, and ether, to which it imparts a yellow color. These solutions deposit indigo-blue on exposure to the air. A solution of this substance constitutes the indigo vat of the dyer.

**Indisine**. See ANILINE (VIOLET).

**Indisputable**, undeniable, not open to cavil; policies of insurance which are not to be questioned when once granted are termed indisputable.

**Indite**, to commit words to writing; to direct or dictate to another.

**Indorsement** is the assigning of a negotiable document, such as a bill of exchange or promissory note, by a writing on the back. The person who assigns is called the *indorser*, the person in whose favor the assignation is made, the *indorsee*. *I.*, in its full and common acceptation, conveys to the indorsee all the rights previously existing in the indorser, with the addition of a claim against the indorser himself. To enable this to be accomplished, however, there must be words intimating an intention on the part of the acceptor to pay to any bearer, or to any person holding right through the original payee, such as, "or order," "or bearer," otherwise the bill is a mere chose in action, and the *I.* does not convey a right against the maker, but merely a claim on the indorser. It is held, however, that negotiable words omitted by mistake may be supplied. In Scotland, every bill or note is negotiable, unless it bear a special restriction. A bill payable simply "to bearer" is transferable without *I.*; but the person who delivers it does not by such act become a party. There is no form of words necessary for an *I.*, — the mere signature of the payee, called a blank *I.*, is a sufficient transference to the bearer. An *I.* with the name of the indorsee, and instructions to pay to him, is an *I.* in full. If a bill is once indorsed blank, it is assignable by delivery, notwithstanding posterior *I.* in full, unless they be restrictive. A restrictive *I.* may restrain the negotiability of a bill. "Pay to A B only," or "Pay to A B for my use," are forms of restrictive *I.* An *I.* is not restrictive from having a consideration on the face of it. An *I.* may be qualified so as to bar the responsibility of the indorser, and merely transfer to the indorsee the claim against the previous parties. The usual form of accomplishing this is by appending to the signature the words *sans recours*. A bill cannot be indorsed for part of its contents after acceptance; but if partly paid, it may be indorsed as to the residue. A person who has delivered a bill without *I.*, when it was the understanding of parties that it should be indorsed, may be compelled in equity to do so; and if he die in the mean time, his executor or administrator may indorse. An indorsee of a bill, who has given value for it, is not liable to objections which may be pleaded against a previous holder, unless aware of them when he took the bill. A bill paid by the party originally liable ceases to be negotiable; but not so a bill paid by an indorser. Where the illegality of the original transaction makes a bill or note

void, an indorsee, however onerous, cannot recover from the original drawee, but the indorser is liable to him, both on the bill and for the original debt. An indorser on whom recourse is intended to be had must receive notice of non-acceptance or non-payment; and though, as between the drawer and drawee, notice may be rendered unnecessary from want of value, this will not affect the indorser's right to notice.

**Indulgence**, a favor granted; an extension of time of payment granted to a debtor; forbearance to press for payment.

**Industrial**, relating to industry: those identified with the manufacturing pursuits, or producing arts, are said to be industrially occupied.

**Industrial Exhibition**, INDUSTRIAL SHOW, a public display of objects of industry, utility, and skill.

**Industrial School**, a trade school; one where some of the mechanical arts or useful occupations are taught.

**Inelegant**, plain; wanting polish or beauty; not handsome.

**Infancy**, strictly, childhood; but, in law, a person under the age of 21, who is not considered answerable for debts incurred.

**Inferior**, of second-rate quality; not the best of anything.

**Inflammable**, easily set on fire.

**Informal**, not regular, or customary; contrary to instructions.

**Information**, intelligence given. — A judicial inquiry and process.

**Inform**, one who lays an information charging a party with some breach of the customs or excise laws; and who receives a moiety of the penalty recovered.

**Infraction**, a breach or violation of a rule, law, or ordinance.

**Infringement**, a violation of an agreement, or right; an infraction of copyright, or of the patent rights of another.

*Patent Law of the U. States — Revised Statutes, Sec. 4919*  
 "Damages for the *I.* of any patent may be recovered by action on the case, in the name of the party interested, either as patentee, assignee, or grantee. And whenever in any such action a verdict is rendered for the plaintiff, the court may enter judgment thereon for any sum above the amount found by the verdict as the actual damages sustained, according to the circumstances of the case, not exceeding three times the amount of such verdict, together with the costs — Sec 4920. In any action for *I.* the defendant may plead the general issue, and having given notice in writing to the plaintiff or his attorney, 30 days before, may prove, on trial, any one or more of the following special matters: 1. That for the purpose of deceiving the public the description and specification filed by the patentee in the Patent Office was made to contain less than the whole truth relative to his invention or discovery, or more than is necessary to produce the desired effect: or, — 2. That he had surreptitiously or unjustly obtained the patent for that which was in fact invented by another, who was using reasonable diligence in adapting and perfecting the same; or, — 3. That it had been patented or discovery thereof prior to his supposed invention or discovery thereof; or, — 4. That he was not the original and first inventor or discoverer of any material and substantial part of the thing patented; or, — 5. That it had been in public use or on sale in this country for more than two years before his application for a patent, or had been abandoned to the public. — And in notices as to proof of previous invention, knowledge, or use of the thing patented, the defendant shall state the names of patentees and the dates of their patents, and when granted, and the names and residences of the persons alleged to have invented, or to have had the prior knowledge of the thing patented, and where and by whom it had been used; and if any one or more of the special matters alleged shall be found for the defendant, judgment shall be rendered for him with costs. And the like defences may be pleaded in any suit in equity for relief against an alleged *I.*: and proofs of the same may be given upon like notice in the answer of the defendant, and with the like effect. — Sec. 4922. Whenever, through inadvertence, accident, or mistake, and without any wilful default or intent to defraud or mislead the public, a patentee has, in his speci-

cation, claimed to be the original and first inventor or discoverer of any material or substantial part of the thing patented, of which he was not the original and first inventor or discoverer, every such patentee, his executors, administrators, and assigns, whether of the whole or any sectional interest in the patent, may maintain a suit at law or in equity, for the *L.* of any part thereof, which was *bona fide* his own, if it is a material and substantial part of the thing patented, and definitely distinguishable from the parts claimed without right, notwithstanding the specifications may embrace more than that of which the patentee was the first inventor or discoverer. But in every such case in which a judgment or decree shall be rendered for the plaintiff no costs shall be recovered, unless the proper disclaimer has been entered at the Patent Office before the commencement of the suit. But no patentee shall be entitled to the benefits of this section if he has unreasonably neglected or delayed to enter a disclaimer."

**Infusible**, incapable of fusion, or of being melted.

**Infusion**, a preparation obtained by pouring boiling water on a substance, as on tea in tea-making.

**Inga Beans**, a Brazilian name for the pods of the horse cassia, or bastard cassia.

**Ingate**, GATE, GEAT, GIT, TEDGE, an aperture in a mould for pouring in metal.

**Ingenio** [Sp.], a steam-engine; a sugar-boiling house.

**Ingenuity**, ready invention; dexterity, skill in any operation.

**Ingot**, a small wedge-shaped mass of metal, as of copper, tin, gold, or silver, etc., of an indefinite size or weight. In some countries ingots of the precious metals pass current, as silver in China.

**Ingredient**, a component part of a compound body; one of many substances.

**Ingrain**, a name given to yarns, wools, etc., dyed with fast colors before manufacturing. *Ingrain carpet*, see CARPET.

**Ingrossing**, purchasing large quantities of corn or other merchandise on speculation, with an expectation of increasing their value.

**Inhaler**, an apparatus used for inhalation of any vapor or volatile matter for medicinal requirements.—A respirator for protecting the lungs from the inhalation of damp or mephitic air.

Many instruments have been devised for inhalation of chloroform, ether, and other anæsthetic agents. One of the best is perhaps the following: A metal box adapted to the shape of the face is made to cover the mouth and nostrils. This piece has two valves, one of which admits the air and vapor from an elastic tube connected with the apparatus containing the substance, and prevents its return; the other valve is a flap opening outwards, which allows the expired air to escape. There is also an adjustment for admitting directly into the mouth-piece more or less atmospheric air. The best plan, however, for administering anæsthetic vapors, is the oldest and simplest, which consists in folding a coarse towel into the form of a small cone, and placing in the bottom a small sponge containing the liquid. At the commencement the sponge should be held at a small distance from the mouth, and the patient be directed to inhale by deep and long-continued inspirations, notwithstanding the cough. As he gets more and more under the influence, it should be approached to the face, but it is imperatively necessary that there should be a free admission of atmospheric air.

**Initials**, the first or capital letters of a name.

**Initiate**, to instruct in the rudiments of an art; to acquaint with.

**Injection**, a medicated liquor thrown into a cavity by a syringe.

**Injection-Pipe**, a pipe for injecting cold water into the condenser of an engine. The entrance of water from the sea, river, or tank, into the pipe, is governed by the injection-valve.

**Injector**, a contrivance for injecting a supply of feed-water into the body of a steam-boiler. Giffard's injector (described under FEED-PUMP), and Sellers's improved injector on the Giffard principle, are the most extensively used injectors.

**Injunction**, a legal prohibition or restraint, as upon the infringement of a patent right.

**Injury**, damage done to goods, fixtures, or rights, etc.

**Ink** [Fr. *encre*; Ger. *Dinte*; It. *inchiostro*; Sp. *tinta*], a pigment or fluid for writing or printing with, of which there are several kinds.

**Bark Writing-Ink**. Gall-nuts, sulphate of iron, and gum are the only substances truly useful in the preparation of ordinary ink; the other things often added merely modify the shade, and considerably diminish the cost to the manufacturer upon the great scale. Many of these inks contain little gallic acid, or tannin, and are therefore of inferior quality. The following receipt gives an excellent ink, black, fluent, and permanent. Digest three quarters of a pound of bruised nut-galls in a gallon of cold water, then add six ounces of sulphate of iron, and an equal weight of gum-arabic, and four or five drops of creosote as an antiseptic. Let the mixture digest for three or four weeks, shaking it up now and then, after which decant the clear fluid. The only improvement of importance which has been made in the manufacture of writing ink from the common materials, during the last few years, is the practice of first roasting the gall-nuts, which is now adopted by a few of the houses most celebrated for their copying ink. In this way a portion of pyrogallic acid is formed, which is very soluble in water, and strikes an intense bluish-black color with the protosulphate or green sulphate of iron. From galls so treated an ink may be made to write black at once. Care must, however, be taken to avoid any loss of materials by volatilization. To prevent any tendency to mouldiness in ink, a few bruised cloves, or a little oil of cloves, or, still better, a few drops of carbolic acid, may be added. The last two should be previously dissolved in a small quantity of strong vinegar or rectified spirit. With the same intention some of the large makers allow the ink to become covered with a skin of "mould" in the cask, to render it less liable to undergo the same change when subsequently bottled.—Ink long exposed to moisture and to the atmosphere turns brown, through becoming converted into peroxide of iron. The writing of documents which has become yellow and pale from age may be restored by passing over it, with a fine brush, a solution of gall-nuts, which, uniting with the iron, re-forms a black gallotannate. Ink-stains submitted to the action of an alkaline carbonate during washing become converted into spots of yellow peroxide, or iron-moulds. These may be removed by dissolving the iron oxide with an acid that will not attack the fibre of the cloth, such as oxalic acid, a weak solution of hydrochloric acid, and several others.

**Blue Ink**. The blue ink first introduced by H. Stephens, of London, is remarkable for a blue color, which soon after drying changes to deep black, for perfect fluidity, and tenacious adherence to the paper. It is a tanno-gallate of iron dissolved in sulphate of indigo, the coloring matter thus not being suspended as in the ordinary inks, but in complete solution. Hornung's receipt is to mix 4 parts of solution of perchloride of iron with 750 parts of water, and precipitate with 4 parts of cyanide of potassium in solution; the precipitate collected is washed with several additions of water, and allowed to drain until it weighs about 200 parts; it is then dissolved in one part of oxalic acid.

**Copying Ink**. This is usually prepared by adding a little sugar or other saccharine matter to ordinary black ink, which for this purpose should be very rich in color, and preferably made with galls prepared by heat, as noticed above. Writing executed with this ink may be copied within the space of 5 or 6 hours, by passing it through a press in contact with thin unsized paper, slightly damped, enclosed between two sheets of thick oiled or waxed paper, when a reversed transcript will be obtained, which will read in proper order when the back of the copy is turned upwards.

**Indelible Ink**. Many formulæ have been given for indelible inks, but they are all inferior in simplicity and usefulness to the one now prescribed. Solution of nitrate of silver thickened with gum, and written with upon linen or cotton cloth, previously imbued with a solution of soda, and dried, is the ordinary permanent ink of the shops. Before the cloths are washed, the writing should be exposed to the sunbeams, or to bright daylight, which blackens and fixes the oxide of silver. It is easily discharged by chlorine and ammonia. A good permanent ink may be made by mixing a strong solution of chloride of platinum with a little potash sugar, and gum to thicken. The writing made therewith should be passed over with a hot smoothing-iron to fix it.

**Indian and Chinese Ink** consists of cakes made of lamp-black and size, or animal glue. The Chinese, however, in manufacturing this ink, do not use animal glue, but vegetable juices, which render it more brilliant and lasting. When Indian ink is prepared with the best lamp-black, levigated with the finest gelatine, or solution of glue, it forms an ink of good color, but wants the shining fracture and permanency of Chinese ink. Indian ink is used in Europe for designs in black and white, in which it possesses the advantage of being able to afford gradations of tone according to the degree of its dilution with water.

**Printing Ink** consists essentially of a mixture of lamp-black,

finely divided carbon, and oil. The qualifications of a good printing ink are: 1. That it should distribute freely and easily, and work sharp and clean; 2. that it should not have too much tenacity for the type, but should have a much greater affinity for the paper, and so come off freely upon it; 3. it ought to dry almost immediately on the paper, but not dry at all upon the type or rollers; this is particularly necessary in newspaper printing; 4. it should be able to withstand all the effects of time and chemical reagents, and should never change color. The quality of the linseed-oil employed, and even the character of the seed from which the oil is obtained, requires great attention. In making printing-ink, the linseed oil is first clarified from all fatty matters, and the pure oil is boiled at a carefully regulated temperature. During the boiling the best pale yellow soap is added, and the required driers are then mixed with it. The best lamp-black is obtained from the smoke of naphtha, the combustion of which has been regulated with care. This black is ground up intimately with the drying oil, which has assumed almost the character of a varnish, and the ink is complete. Excellent receipts for this ink will be found in *Ure's Dictionary of Manufactures*.

**Red Ink** may be made by infusing, for three or four days in weak vinegar, Brazil wood chipped into small pieces; the infusion may be then boiled upon the wood for an hour, strained, and thickened slightly with gum-arabic and sugar. A little alum improves the color. A decoction of cochineal with a little water of ammonia forms a more beautiful red ink, but it is fugitive. An extemporaneous red ink of the same kind may be made by dissolving carmine in weak water of ammonia, and adding a little mucilage.

**Sympathetic Inks** are such as are invisible until heat or some other power is employed to develop them. A dilute solution of chloride of copper, used for writing, is invisible until the paper is heated, when the letters are seen of a beautiful yellow, disappearing with the heat that developed them. The addition of a salt of nickel renders them green.

**Yellow Ink** is made by dissolving 3 parts of alum in 100 of water, adding 25 parts of Persian or Avignon berries bruised, boiling the mixture for an hour, straining the liquor, and dissolving it in 4 parts of gum-arabic. A solution of gamboge in water forms a convenient yellow ink. By examining the different dyestuffs and considering the processes used in dyeing with them, a variety of colored inks may be made.

**Ink-Block**, in printing, a block on which the ink is spread, to be taken up by the balls or rollers.

Fig. 286. — HAND INKING-ROLLER.

**Inking-Roller**, a roller with handles (Fig. 286), used by printers for spreading ink over type, wood-cut blocks, or engraved plates.

**Inking-Table**, a table of peculiar construction, used by letter-press printers to supply the roller with the requisite quantity of ink during the process of printing.

**Inkle**, a species of broad linen tape. Unwrought inkle, or short spinel, is bleached yarn.

**Inkstand**, a tray or stand for holding an ink-bottle, pens, etc.

**Inlaid Work**. See *Buhl*, *Marquetry*, *Mosaic*, *Parquetry*, *Pietra Dura*, etc.

**Inland Bills**, drafts and bills of exchange, drawn and payable in the same State.

**Inland Trade**, interior or domestic trade; the home transport and supply of goods over the country, and which does not pass the sea.

**Inlayer**, a mosaic-worker; a cabinet-maker who ornaments work with veneers or devices in various-colored woods; a manufacturer of papier-mâché who inserts nacreous shell into a prepared ground.

**Inlet**, an entrance. — A creek or bay. — Inserted materials.

**Inmate**, a lodger; an occupier; the member of a household; one who lives with a family.

**Inn**, an English tavern or hotel; a place of lodging and entertainment; differing from a public or ale-house, which does not usually provide beds or food for travellers.

**Innovation**, a novelty or change; a departure from old practices, laws, or customs.

**Input** [Scotch], the share in a contribution; the balance in change of money.

**Inquest**, a judicial inquiry or examination.

**Inquiry**, a scrutiny or investigation; a close examination.

**Inscribe**, to write or engrave on anything; to mark with characters; to address or dedicate.

**Inscription**, a writing or title on a tomb, or on an address; a piece of plate presented, etc.

**Insect Powder**, **Persian Powder**, the powdered flowers of *Pyrethrum carneum*, a Caucasian plant, used for the destruction of vermin.

**Insertions**, narrow strips of lace, embroidered muslin, or cambric, sold for inlets in handkerchiefs, dresses, etc.; work in general added, or joined, to enlarge or ornament ladies' fancy-work.

**Inset**, **Offcut**, in book-binding, one leaf or more of printed paper, set in the middle of a folded sheet, and bound with it.

**Insides**, passengers in the interior of a vehicle. — Perfect paper, from which the outsides or faulty sheets have been removed.

**Insignia**, badges of office; decorations.

**Insoles**, a thickness of cork, felt, paper, etc., placed inside a shoe to protect the sole of the foot, or to improve the fit of the shoe.

**Insolvency**, **Bankruptcy**. An insolvent, or bankrupt, is, in a general sense, a person who is unable to pay his collective debts. A creditor is a person who trusts another with his property, and who thereupon puts himself in a position which is, as contrasted with the debtor, naturally and comparatively defenceless. To sustain and protect him, the law, in all civilized communities, lends its power to constrain the debtor into the fulfilment of his contract. In the French law of bankruptcy, which in its excellent characteristic particulars has been admitted into many European countries, and is still making progress, insolvency is distinguished from bankruptcy, and bankruptcy itself is divided into simple and fraudulent. In England, as in the U. States, the term *bankrupt* is now equivalent to insolvent, and both are indifferently applied to designate any individual unable to pay his debts. All classes of individuals, even those who have least to do with industrious undertakings, are exposed to vicissitudes and misfortunes, the occurrence of which may render them incapable of making good the engagements into which they have entered, and render them bankrupt or insolvent. But though bankruptcy be most frequently, perhaps, produced by uncontrollable causes, it is frequently also produced by persons living beyond their means, and by their repugnance to make those retrenchments which the state of their affairs imperatively demands; and sometimes, and we regret to have to add, not infrequently, bankruptcy originates in fraud or bad faith. But, however it may be occasioned, whether by the misfortunes, the folly, or the fraud of the individual, it ought, *prima facie*, to be viewed as a very grave

moral offence. No man is justified in entering into engagements, or making promises, which he has not a reasonable prospect of being able to fulfil; nor is he justified in applying the money or loans that may have been made to him, or the property that may have come into his hands in the course of his business, to maintain an expenditure that decidedly exceeds his ordinary income or profits. Those who persevere in a system of this sort cannot, if they think at all, expect to arrive at any goal other than bankruptcy. They must know that they are carrying on a system of deception; that they are contracting debts which they can never pay; and that, in truth, they are as really swindlers as if they had offered fictitious bills or dock-warrants in payment of their bonds. And hence the difficulty of dealing with this subject. Misfortunes, when they really occur, or the failure of reasonable speculations, are easily dealt with; but all bankruptcies not at once accounted for in that way involve serious grounds of suspicion, and should be thoroughly sifted. Inasmuch, however, as the circumstances which end in bankruptcy are often of a very complicated character, and difficult to disentangle, it is not easy to lay down any general rules for dealing with them. And hence it is that the laws with respect to bankruptcy have differed very widely in different countries and periods of society, and that it is not, perhaps, possible to suggest any system against which pretty plausible objections may not be made. The U. States bankrupt law of March 2, 1867, though defective in several of its dispositions, was a great improvement on the past, by securing uniform commercial legislation through a country whose commercial interests are so intimately connected. Every business man can study and master the law of his own State; but few are those who have time and facilities to get acquainted with the almost inextricable complications of thirty-seven laws, frequently differing the one from the other on the most essential points. The uncertainty resulting from separate State legislation on commercial matters is certainly the greatest check to confidence, and therefore the repeal of the national law of 1867 (see *BANKRUPTCY*) is much to be regretted. Since the repeal of that law, the laws of the different States respecting insolvency, assignments for the benefit of creditors, exemptions of property from liability for debts, and attachments of property upon mesne process, have become again of general interest. The following are some of the general rules governing these matters, after which is given a short epitome of the insolvent laws for each State:—

**General Rules.** A discharge in insolvency does not affect the rights of a creditor, who is not within the jurisdiction of the State when the discharge is granted, and does not submit himself to that jurisdiction by proving his claim against the estate of the debtor. In the absence of statutes, assignments of property for the benefit of creditors are valid, even though they provide for preferences, and for a release of the debtor by creditors taking the benefit of them. An involuntary assignment will not prevail against attaching creditors in the second State. A voluntary assignment will not prevail against a prior attachment, nor against a subsequent attachment, unless the assignment is valid under, and executed with, the formalities required by the laws of the State where the property is attached.

**Alabama.** No insolvent law. Original attachments, foreign and domestic, are issued by judges of the circuit or county courts, or justices of the peace. An attachment may issue, although the debt or demand of the plaintiff be not due; and shall be a lien on the property attached, until the debt or demand becomes due, when judgment shall be rendered and execution issued. A non-resident plaintiff may have an attachment against the property of a non-resident defendant; provided he gives good and sufficient resident security in the required bond; making oath that the defendant has not sufficient property within the State of defendant's residence to satisfy the

debt or demand. Exemptions: homestead, \$2,000; selected personal property, \$1,000.

**Arizona.** No insolvent or assignment law. Attachments issue in action upon contract for direct payment of money when plaintiff has no security, or when defendant is not resident, etc. The plaintiff must give bond. Exemptions: homestead, \$5,000; certain personal property, \$1,200; domestic animals, etc.

**Arkansas.** No insolvent law. An attachment may be issued against the property of a non-resident; and also against a resident of the State when the latter is about to remove out of the State; or is about to remove his goods or effects; or about to secrete himself so that the ordinary process of law cannot be served on him. Exemptions: homestead, \$2,500; personal property of head of family, \$500.

**California.** An insolvent law, by which a debtor surrendering his property may receive a discharge from his debts. No preferences permitted. No discharge in case of fraud, nor from debts due as a depository of funds received as banker, broker, or commission merchant. Creditors may proceed by attachment: 1. When the defendant has absconded, or is about to abscond from the State, or is concealed therein to the injury of his creditors; 2. when the defendant has removed, or is about to remove, any of his property out of the State, with intent to defraud his creditors; 3. when the defendant fraudulently contracted the debt, or incurred the obligation, respecting which the suit is brought; 4. when the defendant is a non-resident; 5. when he has fraudulently conveyed, disposed of, or concealed his property, or a part of it, or intends to convey the same to defraud his creditors. In California the real estate shall be bound, and the attachment shall be a lien thereon, although the debt or demand due the plaintiff be not due,—in case the defendant is about to remove himself or his property from the State. The law of attachment applies in California, when the contract has been made in that State, or when made payable in that State. Exemptions: homestead, \$5,000, or, if party is unmarried, \$1,000; household articles, \$200; library, etc.

**Colorado.** No insolvent or assignment law. Attachments (plaintiff giving bond) when defendant is non-resident, or conceals himself, or stands in defiance of officer, or in the case of fraud, etc. Exemptions: to head of family, homestead, \$2,000; tools and stock, \$200; wearing-apparel, household goods, and furniture, \$100; library of professional men, \$300; animals, farming tools, etc.

**Connecticut.** Insolvent law, with compulsory proceedings, which may be taken by creditor to amount of \$100. Property put into hands of trustee. Discharge from debts proved, upon payment of seventy per cent. Debtors' property exempt for two years from legal process upon debts which might have been proved. Attachment may be granted against the goods and chattels and land of the defendant; and likewise against his person when not exempted from imprisonment on the execution in the suit. The plaintiff to give bonds to prosecute his claim to effect. Exemptions: necessary wearing-apparel and furniture.

**Dakota.** No insolvent law. Assignments without preferences allowed, but are void against any creditor not assenting thereto, if they tend to coerce the creditor to release his claim, or provide for payment of fraudulent claim, or reserve any benefit to assignor, or confer any power upon assignee, which may delay the conversion of the assigned property, or exempt the assignee from liability from neglect of duty, etc. Attachments (plaintiff giving bond) when defendant is non-resident, absconds, conceals, or conveys property in fraud of creditors, etc. Exemptions: one acre in town, or 160 acres in country, with buildings; selected personal property, \$1,500, besides absolute exemption.

**Delaware.** No insolvent law. Assignments governed by the common law, except that a special partnership may not give preferences. A writ of domestic attachment issues against an inhabitant of Delaware when the defendant cannot be found; or has absconded with intent to defraud his creditors; and a writ of foreign attachment when the defendant is not an inhabitant of this State. This attachment is dissolved by the defendant's appearing and putting in special bail at any time before judgment. Exemptions: personal property, \$275.

**District of Columbia.** No insolvent or assignment laws, except that assignments of the property of a special partnership, with preferences, are void. Attachment (plaintiff giving bond) when the defendant is non-resident, or removes or is about to remove his property, etc. Exemptions: clothing, furniture, \$300; tools, \$200; library, \$400; provisions, etc.

**Florida.** No insolvent or assignment law. Attachments (the plaintiff giving bond) when defendant is non-resident, or about to part with his property fraudulently, or remove from the State, or fraudulently secretes property, etc. Exemptions: homestead, 160 acres in country, half-acre in city, with buildings; personal property, \$1,000.

**Georgia.** No insolvent law. Assignments regulated by a statute, which forbids preferences, or making a release of the debtor a condition precedent to receipt of dividends. A judge of the superior court, or a justice of the inferior court, or a justice of the peace, may grant an attachment against a debtor whether the debt be matured or not, when the latter is remov-

ing without the limits of the State, or any county, or conceals himself. The remedy by attachment may be resorted to by non-resident as well as by resident creditors. The necessary affidavit may be made before any commissioner appointed by the State to take affidavits. Indorsers of notes, obligations, and all other instruments in writing, are entitled to the same remedy as provided for securities. In all cases the attachment first served shall be first satisfied. No lien shall be created by the levying of an attachment, to the exclusion of any judgment obtained by any creditor, before judgment is obtained by the attaching creditor. Exemptions: homestead to head of family, \$1,000; personal property, \$1,000.

**Idaho.** Insolvent law, under which the debtor is discharged upon making an assignment, as therein provided, except in cases of fraud. Attachments (plaintiff giving bond) in actions upon contract for the direct payment of money, when the plaintiff has no lien or security, or when the defendant is a non-resident, etc. Exemptions: homestead, \$5,000; certain enumerated personal property.

**Illinois.** No insolvent law. Assignments, without preference, allowed and regulated by statute. Attachments (plaintiff giving bond) when defendant is non-resident, absconds, conceals himself or his property, is guilty of fraud, etc. Exemptions: homestead, \$1,000; furniture, \$100; selected property, \$100; certain farm stock.

**Indiana.** No insolvent law. Assignments, without preference or provision for release of debtor, allowed and regulated by statute. Attachments substantially same as Illinois. Exemptions: real or personal, at option of debtor, \$300.

**Iowa.** No insolvent law. Assignments, without preference, allowed and regulated by statute. The plaintiff may cause any property of the defendant, which is not subject to execution, to be attached at the commencement, or during the progress, of the proceedings, whether the claim be matured or not; provided an affidavit is filed to the effect that the defendant is a foreign corporation, or acting as such, or that he is a non-resident of the State, or (if a resident) that he is in some manner about to dispose of or remove his property out of the State. Exemptions: homestead, half-acre in town, forty acres in country, with buildings thereon; enumerated personal property, \$1,200.

**Kansas.** No insolvent law. Assignments, without preference, allowed and regulated by statute. Attachment substantially as in Illinois. Exemptions: homestead, one acre in town, 160 acres in country, with improvements; furniture, \$300; and other enumerated articles of personal property.

**Kentucky.** No insolvent law. Assignments regulated by statute. Any preference may be set aside in six months. The plaintiff may have an attachment against the property of the defendant: 1, when the latter is a foreign corporation, or a non-resident of this State; or, 2, who has been absent therefrom four months; or, 3, has departed from the State with intent to defraud his creditors; or, 4, has left the county of his residence to avoid the service of a summons, or conceals himself that a summons cannot reach him; or, 5, is about to remove his property, or a material part thereof, out of the State; or, 6, has sold or conveyed his property with the intent to defraud his creditors, or is about so to sell or convey. Such attachment is binding upon the defendant's property in the county from the time of the delivery of the order to the sheriff. Exemptions: homestead, \$1,000; furniture, \$100; some farming stock, etc.

**Louisiana.** Insolvent law, with compulsory proceedings by a judgment creditor, upon return of the execution "no property found." The debtor makes a surrender to the creditors, and may be discharged by consent of a majority of creditors in number and amount, except in case fraud or preference is proved. Assignments without preference may be made without regard to the insolvent law. A creditor may obtain an attachment against the property of his debtor upon affidavit: 1, when the latter is about leaving permanently the State before obtaining or executing judgment against him; 2, when the debtor resides out of the State; 3, when he conceals himself to avoid being cited to answer to a suit, and provided the term of payment have arrived. In the absence of the creditor, the oath may be made by his agent or attorney, to the best of his knowledge and belief. Exemptions: homestead and stock, \$2,000; furniture, etc., \$600.

**Maine.** Insolvent law, passed in 1878, modelled on the U. States bankrupt law of 1867. Voluntary petition may be filed by debtor owing \$300. Involuntary proceedings by at least two creditors, having one fourth in amount of the provable debts. Debtors owing less than \$300 may make an assignment in a summary manner. No percentage is required to be paid to entitle a debtor, for the first time insolvent, to discharge. Attachments within four months from date of filing petition dissolved. Preferences given within two months void, and may be recovered by assignee. Assignments are probably acts of insolvency, and may be set aside by the assignee in insolvency, if made within four months of the filing of the petition. Otherwise, probably good, if without preferences. Attachments on mesne process in all cases. Exemptions: homestead, \$500 (if recorded in proper office); furniture, \$50, and certain specified articles.

**Maryland.** Insolvent law, under which the debtor is discharged upon surrender of his property, except where fraud or

preference is proved. Assignments subject to rules of common law. A creditor may obtain an attachment, whether he be a citizen of Maryland or not, against his debtor, who is not a citizen of this State, and not residing therein. If any citizen of the State, being indebted to another citizen thereof, shall actually run away or abscond, or secretly remove himself from his place of abode, with intent to evade the payment of his just debts, an attachment may be obtained against him. An attachment may be laid upon debts due the defendant upon judgments or decrees rendered or passed by any court of this State, and judgment of condemnation thereof may be had, as upon other debts due the defendant. Exemptions: \$100 selected property; books, tools.

**Massachusetts.** Insolvent law, similar to the U. States Bankrupt law of 1867. Proceedings generally the same, except that involuntary petition may be filed by one creditor, and the acts of insolvency are not so numerous. Discharge upon payment of fifty per cent, or by consent of majority of number and value of creditors. None in case of fraud or preference. Original writs may be framed, either to attach the goods or estate of the defendant, or, for want thereof, to take his body; or, there may be an original summons, either with or without an order to attach the goods or estate. All real estate, or goods and chattels that are liable to be taken in execution, may be attached upon the original writ, in any action in which any debt or damages are recoverable, and may be held as security to satisfy such judgment as the plaintiff may recover. Exemptions: homestead, \$800, upon recording claim in proper office; furniture, \$200; stock and tools, \$100; and certain other articles of personal property.

**Michigan.** Insolvent law, by which a debtor, with the consent of two thirds of his creditors, and upon surrendering his property, may be discharged. Assignments allowed. The grounds of attachment are: 1, that the defendant has absconded, or is about to abscond, or has concealed himself; 2, that he has assigned, or concealed, or is about to remove, his property, with a view to defraud; 3, that he fraudulently contracted the debt, or incurred the obligation, about which the suit is brought; 4, that he is not a resident of the State, or has not resided there three months immediately preceding the suit; 5, that the defendant is a foreign corporation. Exemptions: homestead, 40 acres in country, with house thereon; or, lot and house in town worth \$1,500; household goods, \$250; clothing and library, \$150; tools and implements, \$250.

**Minnesota.** No insolvent law. Assignments without preference, allowed and regulated by statute. Attachment (plaintiff giving bond) when defendant is non-resident, conceals his property, is guilty of fraud, etc. Exemptions: homestead, 80 acres and buildings in country, lot and house in town; furniture, \$500; animals, with food, and farming utensils, \$300; provisions, tools, etc., \$400.

**Mississippi.** No insolvent law. Assignments not requiring a release of the debtor allowed. An attachment against the estate, including real estate, slaves, goods, chattels, etc., of a debtor, when it is shown that he has removed, or is about removing or absconding from the State, or privately conceals himself. Attachment, also, lies against the property of non-resident debtors. It may be obtained before the debt is due for which it issues, when the creditor has ground to believe that the debtor will remove with his effects out of the State, or has removed. Exemptions: homestead, 80 acres, \$2,000; furniture, \$100; professional libraries, \$250; animals, provisions, etc., \$100.

**Missouri.** No insolvent law. Assignments, without preference, allowed and regulated by statute. An attachment may be issued here when the debtor is not a resident of the State; or, if a resident, when he absconds, absents, or conceals himself; or is about to remove his property, or fraudulently convey it, with a view to hinder or delay his creditors; or where the debt was contracted out of the State, and the debtor has secretly removed his effects into this State with intent to defraud. Exemptions: homestead (against all debts subsequent to title), in places of 40,000 inhabitants, \$3,000; in places of less than 40,000 inhabitants, \$1,500; clothing, tools, etc., \$150; furniture, \$100; provisions, \$100.

**Montana.** No insolvent or assignment law. Attachments in action upon contracts to pay money, the plaintiff giving bond in double the value of property attached; also before debt due, if debtor fraudulently disposes of his property to defraud his creditors. Exemptions: homestead, \$2,500; necessary furniture, tools, etc.; books, \$100.

**Nebraska.** No insolvent law. Assignments, without preference, allowed and regulated by statute of 1877. Attachments (the plaintiff giving bond) when defendant is not resident, or conceals property, or is guilty of fraud, etc. Exemptions: homestead in country, 160 acres, with buildings; in town, 20 acres and house, not to exceed \$2,000; if no homestead, \$500 personal property.

**Nevada.** Insolvent law. No percentage or consent required for discharge, which is only from debts mentioned in the schedules. None, if fraud or preference, etc. Assignments forbidden. Attachment (the plaintiff giving bond) in actions upon contract for direct payment of money when plaintiff has no security. Exemptions: homestead, \$5,000, furniture, \$100; domestic animals, tools, etc.

*New Hampshire.* No insolvent law. Assignments, without preference or provision for release of the debtor, allowed and regulated by statute. A writ of attachment may be issued upon the institution of any personal action; and will hold real and personal property, shares of stock in corporations, pews in churches, and the franchise of any corporation authorized to receive tolls, until the period of thirty days from the time of rendering the judgment. Exemptions: homestead, \$500; furniture, \$100; tools, \$100.

*New Jersey.* No proper insolvent law. Assignment law by which the debtor is discharged from the debt proved under assignment, except when the debtor is guilty of fraud or concealment, etc. Attachment when defendant is non-resident, or absconds from his creditors. Exemptions: homestead, \$1,000; personal property, \$200; and all wearing-apparel.

*New Mexico.* No insolvent or assignment law. Attachments substantially as in Illinois. Exemptions: homestead, \$1,000; clothing, tools, books, furniture, etc.

*New York.* Insolvent law, under which the debtor surrendering his property is discharged by consent of the persons representing two thirds of the debts. No discharge if fraud or preference is proved. No involuntary proceedings unless the debtor is imprisoned. Assignments and the duties of assignees have been regulated by acts of 1877 and 1878. The attachment-law is a legal mode by which a title to property may be acquired by operation of law. When the debtor, who is an inhabitant of New York, absconds, or is concealed, a creditor to whom he owes \$100, or any two to whom he owes \$150, or any three to whom he owes \$300, may, on application to a judge or commissioner, and on due proof of the debt, and of the departure or concealment, procure his real and personal estate to be attached; and on due public notice of the proceeding, if the debtor does not within three months return and satisfy the creditor, or appear and offer to contest the fact of having absconded, or offer to appear and contest the validity of the demand and give the requisite security, then trustees are to be appointed, who become vested with the debtor's estate; and they are to collect and sell it, and settle controversies, and make dividends among all his creditors, in the mode prescribed. From the time of the notice, all sales and assignments by the debtor are declared to be void. If the debtor resides out of the State, and is indebted on a contract made within the State, or to a creditor residing within the State, although upon a contract made elsewhere, his property is liable to be attached and sold in like manner; but the trustees are not to be appointed until nine months after public notice of the proceedings. Perishable goods, other than vessels, when attached under the Absconding Debtor Act, may be immediately sold and converted into money; and if the sheriff, under the attachment, seizes property claimed by third persons, he is to summon a jury and to take their inquiry as to the title to the property claimed. If any American vessel belonging to the debtor be attached under these proceedings, it may be released on the claimant of the vessel giving security to pay the amount of the valuation of the vessel to the trustees, or to the debtor, as the case may be; and if it be a foreign vessel claimed by a third person, the attaching creditor must give security to prosecute the attachment, and to pay the damages if it should appear that the vessel belonged to the claimant. A creditor, having an unliquidated demand resting on contract, is a creditor within the Absconding Debtor Act, and competent to apply for the attachment. Any creditor may proceed against an absconding or concealed debtor, being an inhabitant of the State, or against any non-resident debtor, if the contract was made in New York; but if the contract was made elsewhere, then the creditor must be a resident of the State. Exemptions: homestead, \$1,000, must be recorded in the county where situate; clothing, furniture, and supplies; tools, \$25; library, \$50; certain domestic animals, etc.

*North Carolina.* A law by which, upon surrendering his property, the person of the debtor is free from liability to arrest or imprisonment, except when fraud is proved, but the debt is not discharged. Assignments allowed. Attachments substantially as in Illinois. Exemptions: homestead, \$1,000; selected personal property, \$500.

*Ohio.* A law similar to that of North Carolina. Assignments, without preference, allowed and regulated by statute. A creditor may procure, before or after the maturity of the claim, an attachment against the property of a debtor, where the latter is a foreign corporation or a non-resident; or, if a resident, when he has absconded, or left the county of his residence, or conceals himself; or is about to remove or convert his property, with a view to defraud his creditors. When the debtor fraudulently contracted the debt, or incurred the obligation. Exemptions: homestead, \$1,000; or, if no homestead, selected personal property, \$500; clothing, furniture, certain domestic animals, tools, etc.

*Oregon.* Attachments (the plaintiff giving bond) upon all contracts, payment of which is unsecured. Voluntary assignment law dissolves attachments, if made at any time before judgment distributes assets *pro rata* among all creditors presenting claims within three months. Exemptions: books and pictures, \$75; clothing, \$100, and \$50 additional for each member of family if a householder; tools, etc., \$400. Special exemption to householders of 10 sheep, 2 cows, 5 swine, etc. Household goods, furniture, etc., to value of \$300 besides.

*Pennsylvania.* Law similar to that of North Carolina. Assignments without preference allowed and regulated by statute.

Attachments substantially as in Illinois. Exemptions: real or personal property, \$300; clothing, books, etc.

*Rhode Island.* No insolvent law. Assignments allowed and regulated by a recent statute which took effect September, 1878. Attachments, or levies, within sixty days after the same are made or commenced, may be dissolved by an assignment without preferences under the act. Upon the giving of a preference by the debtor, any three creditors holding not less than one third of the debts may petition the supreme court in equity for the appointment of a receiver of his estate, who is to take possession like an assignee in bankruptcy. Preferences given by the debtor within sixty days of the commencement of proceedings are void as under U. States bankrupt law of 1867. There is no provision for the discharge of the debtor. Attachments, when defendant is non-resident, or fraudulently contracted the debt, or conceals or disposes of his property, or has refused to apply his property to the payment thereof. Exemptions: furniture, etc., \$300; tools, etc., \$200.

*South Carolina.* No insolvent law. Assignments according to common law. Attachments substantially as in Illinois. Exemptions: homestead, \$1,000; furniture, tools, etc., \$500.

*Tennessee.* Law as to insolvency and assignments same as in South Carolina. Attachments substantially as in Illinois. Exemptions: homestead, \$1,000; household goods and stock.

*Texas.* Law as to insolvency and assignments same as in South Carolina. Attachments substantially as in Illinois. Exemptions: homestead, \$5,000; furniture, tools, and certain animals.

*Utah.* Law as to insolvency and assignments same as in South Carolina. Attachments (when plaintiff has no security) substantially as in Illinois. Exemptions: homestead, \$1,000; and \$250 for each member of the family; furniture, tools, provisions, etc.

*Vermont.* Insolvent law of 1876, modelled on the U. States bankrupt law of 1867, with involuntary proceedings by one creditor to amount of \$250. No discharge, unless assets equal thirty per cent debts, or by consent of majority in number and amount of debts proved. No discharge also in substantially same cases as in bankrupt law. Assignments appear to be acts of insolvency, which may be set aside by an assignee in insolvency if made within four months of filing his petition. Attachments on *mesne process* in all cases. Exemptions: homestead, \$500; specified articles of furniture, tools, etc.

*Virginia.* No insolvent or assignment laws. Attachments substantially as in Illinois. Exemptions: to a householder, head of a family, real or personal property, \$2,000; library, \$100; wearing-apparel, furniture, etc.

*Washington Territory.* Law as to insolvency and assignments same as Virginia. Attachments substantially as in Illinois. Exemptions: homestead, \$1,000; clothing, libraries, furniture, animals, tools, etc., \$200.

*West Virginia.* No insolvent law. Assignments regulated by statute, preferences being allowed. Attachments same as in Virginia. Exemptions: homestead, \$1,000; personal property, \$200.

*Wisconsin.* Insolvent law, by which debtor is discharged upon surrendering property and complying with law. Assignments, with preferences, unless by limited partnerships, allowed and regulated by statute. Attachments substantially as in Illinois. Exemptions: homestead, forty acres in country, one-fourth acre in town; clothing, furniture, \$200; farming tools, \$50; tools or stock in trade, \$200; printing material or presses, \$1,500; etc.

*Wyoming.* No assignment or insolvent laws. Attachments substantially as in Illinois. Exemptions: homestead, \$1,500; selected personal property, \$500. Exemptions apply to residents of the territory only.

*Arrest for debt.* when nothing unfair or improper is involved in its contraction, still remains in some of the U. States. The policy of such arrest is not a little questionable, and notwithstanding the deference due to the authorities who have vindicated this practice, we confess we are unable to discover anything very cogent in the reasonings advanced in its favor. Provided a person in insolvent circumstances intimate his situation to his creditors, and offer to make a voluntary surrender of his property to them, he has, supposing he has acted honestly, done all that should be required of him, and ought not to undergo any imprisonment. If, indeed, he have deceived his creditors by false representations, or have grossly misconducted himself, or have endeavored to convey away any part of his property, then, undoubtedly, he should be subjected to the pains and penalties attached to swindling; but when such practices are not alleged, or cannot be proved, sound policy, we apprehend, would dictate that creditors should have no power over the persons of their debtors, and that they should be entitled only to their effects. If a tradesman trust an individual with a loan of money or goods which he is unable to pay, he has made a bad speculation. But why should he, because he has done so, be allowed to arrest the debtor's person? If he wished to have perfect security, he either should not have dealt with him at all, or dealt with him only for ready money. Such transactions are, on the part of tradesmen, perfectly voluntary; and if they place undue confidence in a debtor who has not misled them by erroneous representations of his affairs, they have themselves only to blame.

The following table shows the number of failures that occurred throughout the U. States and the Dominion of Canada, with liabilities, for the years 1876, 1877, 1878, and 1879:—

From the foregoing figures it appears that the mercantile failures in the U. States during the year 1879 were in number 6,658, with liabilities aggregating slightly over 98 millions of dollars. The failures of 1878 were in number 10,478, with liabilities of 234 millions. The decrease for the year 1879 is therefore most marked, there having been 3,820 less failures than in the previous year; while the liabilities decreased by 136 millions of dollars.

**Inspection**, a surveillance; an examination.

**Inspector**, a superintendent or overseer.

**Instalments**, a debt divided into several parts, and paid at different times.

**Instant**, the present or current month, abbreviated *inst.*

**Institution**, an organized society for promoting any object, public or social. Thus, a college is termed a *collegiate institution*; an academy of belles-lettres, a *literary institution*; an almsgiving society, a *benevolent or charitable institution*; while a banking company or insurance office is a *commercial institution*.

**Instructor**, a teacher; one who imparts knowledge or skill of any kind.

**Instrument**, a law term for a written document or deed. — A tool used for any purpose; an artificial machine, as mathematical, nautical, philosophical, and electro-magnetic instruments.

**Instrumental**, pertaining to musical instruments.

**Insulate**, to isolate or detach; to separate or cut off, as in electricity.

**Insulator**, a bad conductor of electricity, so called from being used as support for bodies in which electricity is to be retained. When a wire or other conductor is surrounded on all sides by glass, porcelain, or other non-conducting substance, it is said to be *insulated*.

**Insurance**, in its legal definition, is a contract of indemnity, one party engaging to make good to another the pecuniary loss that may be, or may be presumed to be, occasioned by any future or contingent event, in consideration of a sum certain received or promised. The most obvious subjects of *I.* are those which can be measured by a pecuniary value, and to this fair estimate of loss, *I.* by individuals on their own lives is the only exception; a case in which no mischief can arise from the insured valuing his life at the sum for which he can pay the premium of *I.* In this contract, the person who insures is called the *Insurer*, and technically the *Underwriter*, from his writing his name (in marine *I.*) under the sum he will stand good for. The party obtaining the *I.* is called the *Insured*, or the *Assured*, and the deed by which the insurer becomes bound is called a *Policy of Insurance*. — It is the duty of government to assist, by every means in its power, the efforts of individuals to protect their property. Losses do not always arise from accidental circumstances, but are frequently occasioned by the crimes and misconduct of individuals; and there are no means so effectual for their prevention, when they arise from this source, as the establishment of a vigilant system of police, and of such an administration of the law as may be calculated to afford those who are injured a ready and cheap method of obtaining every practicable redress, and, as far as possible, of insuring the punishment of culprits. But, in despite of all that may be done by government, and of the utmost vigilance on the part of individuals, property must always be exposed to a variety of casualties from fire, shipwreck, and other unforeseen disasters; and hence the importance of inquiring how such unavoidable losses, when they do occur, may be rendered least injurious. The loss of a ship, or the conflagration of a cotton-mill, is a calamity that would press heavily even on the richest individual. But were it distributed among several individuals, each would feel it proportionally less; and provided the number of those among whom it was distributed were very considerable, it would hardly occasion any sensible inconvenience to any one in particular. Hence the

advantage of combining to lessen the injury arising from the accidental destruction of property; and it is the diffusion of the risk of loss over a wide surface, and its valuation, that forms the employment of those engaged in *I.*

Though it be impossible to trace the circumstances which occasion those events that are on that account termed accidental, they are, notwithstanding, found to obey certain laws. The number of births, marriages, and deaths; the proportions of male to female, and of legitimate to illegitimate births; the ships cast away; the houses burnt; and a vast variety of other apparently accidental events, — are yet, when our experience embraces a sufficiently wide field, found to be nearly equal in equal periods of time; and it is easy, from observations made upon them, to estimate the sum which an individual should pay, either to guarantee his property from risk, or to secure a certain sum for his heirs at his death. It must, however, be carefully observed that no confidence can be placed in such estimates unless they are deduced from a very wide induction. Suppose, for example, it happens that during the present year one house is accidentally burnt, in a town containing 1,000 houses; this would afford very little ground for presuming that the *average* probability of fire in that town was 1 to 1,000. For it might be found that not a single house had been burnt during the previous 10 years, or that 10 were burnt during each of these years. But supposing it were ascertained that, at an average of 10 years, 1 house had been annually burnt, the presumption that 1 to 1,000 was the real ratio of the probability of fire would be very much strengthened; and if it were found to obtain for 20 or 30 years together, it might be held, for all practical purposes at least, as indicating the precise degree of probability. — Besides its being necessary, in order to obtain the true measure of the probability of any event, that the series of events, of which it is one, should be observed for a rather lengthened period, it is necessary also that the events should be numerous, or of pretty frequent occurrence. Suppose it were found, by observing the births and deaths of 1,000,000 individuals taken indiscriminately from among the whole population, that the mean duration of human life was 40 years; we should have but very slender grounds for concluding that this ratio would hold in the case of the next 10, 20, or 50 individuals that are born. Such a number is so small as hardly to admit of the operation of what is called the *law of average*. When a large number of lives is taken, those that exceed the medium term are balanced by those that fall short of it; but when the number is small, there is comparatively little room for the principle of compensation, and the result cannot, therefore, be depended upon. It is found, by the experience of all countries in which censuses of the population have been taken with considerable accuracy, that the number of male children born is to that of female children in the proportion nearly of 22 to 21. But unless the observations be made on a very large scale, this result will not be obtained. If we look at particular families, they sometimes consist wholly of boys, and sometimes wholly of girls; and it is not possible that the boys can be to the girls of a single family in the ratio of 22 to 21. But when, instead of confining our observations to particular families, we extend them so as to embrace a population of 500,000, these discrepancies disappear, and we find that there is invariably a small excess in the number of males born over the females.

The false inferences that have been drawn from the doctrine of chances have uniformly, almost, proceeded from generalizing too rapidly, or from deducing a rate of probability from such a number of instances as do not give a fair average. But when the instances on which we found our conclusions are sufficiently numerous, it is seen that the most anomalous events, such as suicides, deaths by accidents, the number of letters put into the post-office without any address, etc., form pretty regular series, and consequently admit of being estimated *a priori*. — The business of *I.* is founded upon the principles thus briefly stated. Suppose it has been remarked that of *forty* ships, of the ordinary degree of seaworthiness, employed in a given trade, *I.* is annually cast away, the probability of loss will plainly be equal to *one fortieth*. And if an individual wish to insure a ship, or the cargo on board a ship, engaged in this trade, he ought to pay a premium equal to  $\frac{1}{40}$  of the sum he insures, exclusive of such an additional sum as may be required to indemnify the insurer for his trouble, and to leave him a fair profit. If the premium exceed this sum, the insurer is overpaid; and if it fall below it, he is underpaid.

*I.* are effected mostly by societies, and sometimes by individuals, the risk being in either case diffused amongst a number of persons. Companies formed for carrying on the business have generally a large subscribed capital, or such a number of proprietors as enables them to raise, without difficulty, whatever sums may at any time be required to make losses good. Societies of this sort do not limit their risks to small sums; that is, they do not often refuse to insure a large sum upon a ship, a house, a life, etc. The magnitude of their capitals affords them the means of easily defraying a heavy loss; and their premiums being proportioned to their risks, their profit is, at an average, independent of such contingencies. Individuals, it is plain, could not act in this way unless they were possessed of very large capital; and besides, the taking of large risks would render the business so hazardous, that few would be disposed to engage in it. — When cautiously conducted, the business of *I.* is as safe a line of speculation as any in which individuals can engage. To establish a policy of *I.* on a fair foundation, or in such a way that the premiums paid by the insured shall exactly balance the risks incurred by the insurers, and the various necessary expenses to which they are put, including, of course, their profit, it is necessary, as previously remarked, that the experience of the risks should be pretty extensive. It is not, however, at all necessary that either party should inquire into the circumstances that lead to those events that are most commonly made the subject of insurance. Such a research would, indeed, be entirely fruitless; we are, and must necessarily continue to be, wholly ignorant of the causes of their occurrence. — It is easy to perceive the immense advantages resulting to navigation and commerce from the practice of marine *I.* Without the aid that it affords, comparatively few individuals would be found disposed to expose their property to the risk of long and hazardous voyages; but by its means insecurity is changed for security, and the capital of the merchant, whose ships are dispersed over every sea, and exposed to all the perils of the ocean, is as secure as that of the agriculturist. He can combine his measures and arrange his plans as if they could no longer be affected by accident. The chances of shipwreck, or of loss by unforeseen occurrences, enter not into his calculations. He has

purchased an exemption from the effects of such casualties, and applies himself to the prosecution of his business with that confidence and energy which nothing but a feeling of security can inspire. But, notwithstanding what has now been stated, it must be admitted that the advantages derived from the practice of insuring against losses by sea and land are not altogether unmingled with evil. The security which it affords tends to relax that vigilant attention to the protection of property which the fear of its loss is sure otherwise to excite. This, however, is not its worst effect. The records of our courts, and the experience of all who are largely engaged in the business of *I.*, too clearly prove that ships have been repeatedly sunk, and houses burned, in order to defraud the insurers. In despite, however, of the temptation to inattention and fraud which is thus afforded, there can be no doubt that, on the whole, the practice is, in a public as well as private point of view, decidedly beneficial. The frauds that are occasionally committed raise, in some degree, the rate of *I.* Still it is exceedingly moderate; and it is most probable that the precautions adopted by the *I.* offices for the prevention of fire, especially in great cities, where it is most destructive, outweigh the chance of increased conflagration arising from the greater tendency to carelessness and crime. The business of life *I.* has been carried to a far greater extent in Great Britain and in the U. States than in any other country, and has been productive of the most beneficial effects. Life *I.* are of various kinds. Individuals without any very near connections, and possessing only a limited fortune, are sometimes desirous, or are sometimes, from the necessity of their situation, obliged annually to encroach on their capitals. But should the life of such persons be extended beyond the ordinary term of existence, they might be totally unprovided for in old age; and to secure themselves against this contingency, they pay to an *I.* company the whole or a part of their capital, on condition of its guaranteeing them, as long as they live, a certain annuity, proportioned partly, of course, to the amount of the sum paid, and partly to their age when they buy the annuity. But though sometimes serviceable to individuals, it may be questioned whether *I.* of this sort are, in a public point of view, really advantageous. So far as their influence extends, its obvious tendency is to weaken the principle of accumulation; to stimulate individuals to consume their capitals during their own life, without thinking or caring about the interest of their successors. Were such a practice to become general, it would be productive of the most extensively ruinous consequences. Luckily, however, the species of *I.* now referred to is but inconsiderable compared with that which has accumulation for its object. All professional persons, or those living on salaries or wages, such as lawyers, physicians, military and naval officers, clerks in public or private offices, etc., whose incomes must of course terminate with their lives, and a host of others, who are either not possessed of capital or cannot dispose of their capital at pleasure, must naturally be desirous of providing, so far as they may be able, for the comfortable subsistence of their families in the event of their death. Take, for example, a physician or lawyer, without fortune, but making, perhaps, \$5,000 or \$10,000 a year by his business; and suppose that he marries and has a family: if this individual attain to the average duration of human life, he may accumulate such a fortune as will provide for the adequate support of his family at his

death. But who can presume to say that such will be the case,—that he will not be one of the many exceptions to the general rule?—And suppose that he were hurried into an untimely grave, his family would necessarily be destitute. Now, it is against such calamitous contingencies that life *I.* is intended chiefly to provide. An individual possessed of an income terminating at his death agrees to pay a certain sum annually to an insurance office; and this office binds itself to pay to his family at his death a sum equivalent, after deduction of the expenses of management and the profits of the insurers, to what these annual contributions, accumulated at compound interest, would amount to, supposing the insured to reach the common and average term of human life. Though he were to die the day after the *I.* has been effected, his family would be as amply provided for as it is likely they would be by his accumulations were his life of the ordinary duration. In all cases, indeed, in which those insured die before attaining the average age, their gain is obvious. But even in those cases in which their lives are prolonged beyond the ordinary term, they are not losers,—they then merely pay for a security which they must otherwise have been without. During the whole period, from the time when they effect their *I.* down to the time when they arrive at the mean duration of human life, they are protected against the risk of dying without leaving their families sufficiently provided for; and the sum which they pay after having passed this mean term is nothing more than a fair compensation for the security they previously enjoyed. Of those who insure houses against fire, a very small proportion only have occasion to claim an indemnity for losses actually sustained; but the possession of a security against loss, in the event of accident, is sufficient motive to induce every prudent individual to insure his property. The case of life *I.* is in this respect different. When established on a proper footing, the extra sums which those pay whose lives exceed the estimated duration is but the value of the previous security. In order to adjust the terms of an *I.* that the party insuring may neither pay too much nor too little, it is necessary that the probability of his life failing in each subsequent year should be determined with as much accuracy as possible. To ascertain this probability, various observations have been made in different countries and periods, showing, out of a given number of persons born in a particular country or place, how many complete each subsequent year, and how many die in it, till the whole be extinct. The result of such observations, when collected and arranged in a tabular form, are called “tables of mortality”; being entitled, of course, to more or less confidence, according to the number and species of lives observed; the period when, and the care with which, the observations were made, etc. But supposing these tables to be formed with sufficient accuracy, the expectation of life at any age, or its mean duration after such age, may be readily learned from them; and hence also the value of an annuity, or the assurance on a life of any age. (See INTEREST AND ANNUITIES.) In practice, a life *I.* is seldom made by the payment of a single sum when it is effected, but almost always by the payment of an *annual premium* during its continuance, the first being paid down at the commencement of the *I.* If the table of mortality adopted by the insurers fairly represents the law of mortality prevailing among the insured, it follows that when a party insured

does not attain to the average age according to the table, the insurers will either lose by him or realize less than their ordinary profit; and when, on the other hand, the life of an insured party is prolonged beyond the tabular average, the profits of the insurers are proportionally increased. But if their business is so extensive as to enable the law of average fully to apply, what they lose by premature death will be balanced by the payments received from those whose lives are prolonged beyond the mean duration of life for the ages at which they were respectively insured; so that the profit of the society is wholly independent of chance.

In this part of the work Fire *I.* alone will be considered. The other two great divisions of the contract of *I.* must be looked for under LIFE *I.* (including accidents) and MARINE *I.* A variety of other information, directly or collaterally bearing upon the subject, will be found under the heads ANNUITY, AVERAGE, INTEREST AND ANNUITIES, RE-INSURANCE, REVERSION, etc.

*Fire Insurance.* *I.* against fire is a contract of indemnity, by which the insurer, in consideration of a certain premium received by him, either in a gross sum or by periodical payments, undertakes to indemnify the insured against all loss or damage he may sustain on his houses or other buildings, stock, goods, and merchandise, by fire up to a certain amount during a specified period. *I.* against fire are generally made by joint-stock companies, in which certain persons owning the capital insure at their own risk and for their own profit. Many of these are established in New York, Boston, Philadelphia, and other important cities of the U. States, and operate by agencies throughout the country. There are also a great number of mutual companies (mostly doing local business), in which every one who is insured becomes thereby a member, and the net profits, or a certain proportion of them, are divided among all the members in such a manner as the charter or by-laws of the company may direct. Or both united, in which case there is a capital stock provided, as a permanent guaranty fund, over and above the premium received, and a certain part or proportion of the net profits is paid by way of dividend upon the fund, and the residue divided among the insured. — The conditions on which the different companies insure are contained in their *proposals*, and are also printed on the back of every policy; and it is in most instances expressly conditioned that they undertake to pay the loss, not exceeding the sum insured, “according to the exact tenor of their printed proposals, or according to the conditions.” — Nothing can be recovered from the insurers, in the event of loss, unless the party insuring had an interest or property in the thing insured at the time when the insurance was effected, and when the loss happened. It often occurs that one office will not insure to the full amount required by an individual who has a large property; and in such case the party, to cover his whole interest, is obliged to insure at different offices. But, in order to prevent the frauds that might be practised by insuring the full value in various companies, there are, in the proposals issued by all the companies, articles which declare that persons insuring must give notice of any other *I.* made elsewhere upon the same houses or goods, that the same may be specified and allowed by indorsement on the policy, in order that each office may bear its ratable proportion of any loss that may happen; and sometimes a clause is added, providing that unless such notice be given of each *I.* to the company where another *I.* is made on the same effects, the *I.* made without such notice will be void. — Any trustee, mortgagee, reversioner, factor, or agent has sufficient interest in the goods under his custody to effect a policy of *I.*, provided the nature of such interest be distinctly specified at the time of executing such policy. — The risk commences in general from the time the proposal is accepted by the company, unless there be some other time specified. — Policies of *I.* may be effected for any period. If for a year (which is most customary) or for a term of years by a single payment, it is usual for the office, by way of indulgence, to allow fifteen days after each year, or term of years, for the payment of the premium for the next period in succession; and provided the premium be paid within that time, the insured is considered within the protection of the office. — A policy of *I.* is not in its nature assignable, nor can it be transferred without the express consent of the office. When, however, any person dies, his interest remains in his executors or administrators respectively, who succeed or become entitled to the property, provided such representatives respectively procure their right to be indorsed on the policy. Insurers against fire are not held to pay for loss of profits, gains of business, or other indirect and remote consequences of a loss by fire. In marine *I.*, if a proportion only of the value is insured, the insured is considered as his own insurer for the residue,

and only an equal proportion of the loss is paid. Thus, if on a ship valued at \$10,000, \$5,000 be insured, and there is a loss of one half, the insurers pay only one half of the sum they insure, just as if some other party had insured the other \$5,000. But in a fire policy, the insurers pay in all cases the whole amount which is lost by the fire, provided only that it does not exceed the amount which they insure. The general average clauses or provisions which are inserted in fire policies in England are not known here. — The companies insure generally against loss or damage by fire all descriptions of buildings, including mills and manufactories, and goods, wares, and merchandise in the same; ships in harbor or in dock; craft on navigable rivers and canals, and the goods laden on the same; cars travelling the roads and railroads, and their contents; and farming stock of all descriptions. — *I.* are generally divided into *common*, *hazardous*, *extra-hazardous*, etc., according to the nature of construction and surroundings of the buildings, trades which are carried on, etc., and the scale of premiums is materially affected by the nature of the risk; it is, therefore, extremely important that the insured should not deceive the insurers on this point. These rules are, however, usually liberally constructed. Thus if "storing" certain goods qualified hazardous demands an extra premium, having a small quantity for home consumption, and perhaps even for sale, does not come within the meaning of this clause. — The rates of premiums differing in most of the States, and being generally, chiefly of late, subject to frequent fluctuations, we purposely avoid giving any figures. — When the insured proposes to make any alteration in the premises insured, he should make this known to the insurers, and obtain their leave in writing. Mere alterations, however, if they do not substantially increase the risk, would probably not avoid a policy. — The risk insured against is fire, or ignition. To enable the insured to recover, something must have been actually on fire which ought not to have been on fire; and so the effects of heat radiating from fire in its proper place are not included. If there be ignition, however, though not of the subject insured, the injury occasioned by the event is within the policy, though more immediately caused by the efforts to protect the subject from the fire, as by water poured upon it, or the removal of furniture. A loss by lightning is not a loss by fire, unless the property be lost by ignition caused by the lightning. An explosion of or by gunpowder is a loss by fire, while it appears that an explosion of or by steam is not so. — The method and operation of fire *I.* have become quite uniform throughout the country, and any company may appeal to the usage of other companies to answer questions which have arisen under its own policy; only, however, within certain rules, and under some well-defined restrictions. In the first place, usage may be resorted to for the purpose of explaining that which needs explanation, but never to contradict that which is clearly expressed in the contract. And no usage can be admitted, even to explain a contract, unless the usage be so well established and so well known that it may reasonably be supposed that the parties entered into the contract with reference to it. Thus if under a policy against fire on a vessel in one part of this country, an inquiry is raised as to the local usage, the policy is not to be affected by proof of usage upon any particular matter in other parts of the world, or even of the U. States. And not only the terms of the contract must be duly regarded, but those of the charter; thus if this provides that "all policies and other instruments made and signed by the president, or other officer of the company, shall bind the company," an agreement to cancel the policy should be signed; although it cannot be doubted that a party insured might otherwise give up his policy, or renounce all claim under it, and that a valid agreement to that effect between him and the company would not be set aside for his benefit, on the ground of a merely formal defect. — The contract of fire *I.* being, to a great extent, ruled by the same principles which affect marine *I.*, so far as these are applicable to the nature of the contract, we refer to MARINE INSURANCE for further information. Reference is also given to any of the offices of the companies, or their agencies, where a particular account of the conditions on which *I.* are granted may be readily obtained.

Table showing the business transacted in the State of New York during the year 1878 by joint-stock Fire and Fire-marine Insurance Companies of that and other States and Foreign Countries, and by Mutual Companies of other States: —

COMPANIES.	Fire premiums received in 1878.	Fire losses paid in 1878.	Risks written.	Ratio of losses to	
				Risks written.	Fire premiums received.
New York Joint-stock Cos.....	\$ 7,850,325	\$ 2,652,833	\$ 1,679,090,799	13	34.91
Other States Joint-stock Cos.....	3,088,564	1,842,494	474,696,371	43	58.52
Other States Mutual Cos...	130,176	118,480	14,316,502	85	93.35
Am. Branches of Foreign Cos..	3,041,073	1,380,023	473,382,489	29	45.43

Each of the 165 American Companies authorized to transact business in the State of New York for the year 1878 has a special article at its alphabetical order in this work, and in the Appendix at end of the book.

**Insurance Broker or Agent**, a person whose business is to procure or effect marine, fire, or life insurances for the account of companies, from whom he receives a percentage or a commission on the business which they accept.

**Insurance Co. of North America**, a fire and marine insurance Co., located in Philadelphia, Pa., organized in 1794. *Statement*, Jan. 1, 1879: Cap. stock, paid up in cash, \$2,000,000; net surplus, \$2,480,078.93; total cap. and surplus, \$4,480,078.93; risks in force, fire, \$172,402,061; marine and inland, \$6,248,218; premiums, fire, \$2,284,504.09; marine and inland, \$290,632.26. Premiums received since the organization of the Co., \$74,000,000; losses paid, \$45,533,706.24; cash dividends paid to stockholders, \$9,650,000.

**Insurance Co. of the State of Pennsylvania**, a fire and marine insurance Co., located in Philadelphia, Pa., organized in 1794. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$200,000 (total net assets, \$639,451.11; liabilities, including cap. stock paid up in cash, \$424,708.01); net surplus, \$214,743.10; total cap. and surplus, \$414,743.10; risks in force, fire, \$16,669,464; premiums, \$146,127.66; marine and inland risks, \$1,445,210; premiums, \$35,778.77. Premiums received since the organization of the Co. (not given); losses paid, \$12,000,000; cash dividends paid to stockholders, \$3,956,406.

**Intaglio**, a name given to small gems in which the design is indented, or engraved, instead of being raised, as in cameos. It is the method employed in the engraving of seals.

**Integer**, a whole quantity or number, in contradistinction to a fractional part.

**Intelligence Office**, an office where information may be obtained; a servant's registry; a telegraph office, etc.

**Intendant**, in France, an inspector or superintendent.

**Intense Blue**, a preparation of refined indigo.

**Intercourse**, communication or correspondence; trade.

**Interdict**, a prohibition.

**Interest and Annuities**. In the commercial acceptance of the term, *I.* is the consideration agreed to be paid for the use of money. The sum on which the *I.* is reckoned is called the *Principal*, and the sum per cent agreed on as *I.*, the *Rate*. The latter, viewed apart from legislative interference, is in the general case determined by: 1st, the average rate of profit derived from the employment of capital; 2d, the security afforded for the repayment of the principal; and 3d, the duration or convertibility of the loan. That the rate of *I.* allowed on borrowed capital must, in the general case, bear a proportional relation to the average rate of profit yielded by its employment, seems evident. Much will be given for the use of money when much can be made of it; but, on the other hand, no man will pay more for its use than he has a prospect of making by its investment. Hence, in countries where the facilities for the advantageous employment of capital are great, *I.* is high; while in countries when these facilities are comparatively less, *I.* is low. In fact, the rate of *I.* is nothing more than the *net* profit on capital; whatever returns are obtained by the borrower, beyond the *I.* he has agreed to pay, really accrue to him on account of risk, trouble, or skill, or of

advantages of situation and connection. But besides fluctuations in the rate of *I.* caused by the varying productiveness of industry, the rate of *I.* on each particular loan must of course vary according to the supposed solvency of the borrowers, or the degree of risk supposed to be incurred by the lender, of either not recovering payment at all, or not recovering it at the stipulated term. No person of sound mind would lend on the personal security of an individual of doubtful character and solvency, and on mortgage over a valuable estate, at the same rate of *I.* Wherever there is risk, it must be compensated to the lender by a higher premium, or *I.* And yet, obvious as this principle may appear, all governments have interfered with the adjustment of the terms of loans; some to prohibit *I.* altogether, and others to fix certain rates which it should be deemed legal to charge, and illegal to exceed. It is needless to waste the reader's time by entering into any lengthened arguments to show the inexpediency and mischievous effect of such interferences. This has been done over and over again. It is plainly in no respect more desirable to limit the rate of *I.* than it would be to limit the rate of insurance, or the prices of commodities; and though it were desirable, it cannot be accomplished. The real effect of all legislative enactments having such an object in view is to increase, not diminish, the rate of *I.* When the rate fixed by law is less than the market or customary rate, lenders and borrowers are obliged to resort to circuitous devices to evade the law; and as these devices are always attended with more or less trouble and risk, the rate of *I.* is proportionally enhanced. In England, a statute was passed in 1554 authorizing lenders to charge 10 per cent *I.*; in 1624 the legal rate was reduced to 8 per cent; and in the reign of Queen Anne it was further reduced to 5 per cent, at which it still continues. It is enacted by the statute (12 Anne c. 16) making this reduction, that "all persons who shall receive, by means of any corrupt bargain, loan, exchange, chevance, or *I.* of any wares, merchandise, or other thing whatever, or by any deceitful way or means, or by any covin, engine, or deceitful conveyance for the forbearing or giving day of payment, for one whole year for their money or other thing, above the sum of £5 for £100, for a year, shall forfeit for every such offence the *treble* value of the moneys, or other things, so lent, bargained, etc." This enactment, which had been repeatedly condemned by committees of the English legislature, was at length substantially repealed by the Act 2 and 3 Vict. c. 37, which exempts bills of exchange not having more than 12 months to run, and contracts for loans of money above £10, from its operation.

The rate of *I.* and usury widely differ in the different States of the American Union. In Massachusetts, for instance, by act of March 6, 1867, it was enacted that "it shall be lawful to contract to pay or reserve discount at *any rate*, and to contract for payment and receipt of *any rate of I.* provided, however, that no greater rate of *I.* than 6 per cent per annum shall be recovered in any action, except when the agreement to pay such greater rate of *I.* is in writing." In New York, on the other side, the act of June 20, 1879, reducing the rate of *I.* from 7 to 6 per cent from the 1st of January, 1880, has retained the old and heavy penalties of the usury laws of that State. The following statement shows the *I.* laws of the different States and Territories of the Union, with the penalty of usury:—

State.	Rate per cent.		Penalty of Usury.
	Legal.	Special.	
Alabama.....	8	..	Loss of <i>I.</i>
Arizona.....	10	..	None.
Arkansas.....	6	..	Forfeiture of prin. and <i>I.</i>
California.....	10	..	None.
Colorado.....	10	..	None.
Connecticut.....	6	..	None.
Dakota.....	6	..	None.
Delaware.....	6	..	Forf. of contract.
Dist. of Columbia.	6	..	Forf. of all <i>I.</i>
Florida.....	8	..	None.
Georgia.....	7	..	Forf. of all <i>I.</i>
Idaho.....	10	..	\$100, or imprisonment 6 months, or both.
Illinois.....	6	..	Forf. of all the <i>I.</i> (Act of May 24, 1879).
Indiana.....	6	..	Forf. of <i>I.</i> over 10 per cent.
Iowa.....	6	..	Forf. of <i>I.</i> and costs.
Kansas.....	7	..	Forf. of excess over 12 per cent.
Kentucky.....	6	..	Forf. of excess of <i>I.</i>
Louisiana.....	5	..	Forf. of <i>I.</i>
Maine.....	6	..	None.
Maryland.....	6	..	Forf. of excess.
Massachusetts.....	6	..	None.
Michigan.....	7	..	Forf. of excess.
Minnesota.....	7	..	Forf. of cont. if more than 12 per cent is charged.
Mississippi.....	6	..	Forf. of <i>I.</i> over 10 per cent.
Missouri.....	6	..	Forf. of all <i>I.</i>
Montana.....	10	..	None.
Nebraska.....	10	..	Forf. of all <i>I.</i> and costs.
Nevada.....	10	..	None.
New Hampshire.....	6	..	Forf. of three times the <i>I.</i> received.
New Jersey.....	6	..	Forf. of all <i>I.</i> and costs.
New Mexico.....	6	..	None.
New York State.....	6	..	Forf. of cont.; \$1,000 fine; 6 months' imprisonment.
North Carolina.....	6	..	Forf. of double amt. of <i>I.</i>
Ohio.....	6	..	Forf. of excess.
Oregon.....	10	..	Forf. of <i>I.</i> , prin., and costs.
Pennsylvania.....	6	..	Forf. of excess.
Rhode Island.....	6	..	Forf., unless a greater rate is contracted.
South Carolina.....	7	..	Forf. of all the <i>I.</i>
Tennessee.....	6	..	Forf. of excess.
Texas.....	8	..	Forf. of all <i>I.</i>
Utah.....	10	..	None.
Vermont.....	6	..	Forf. of excess.
Virginia.....	6	..	Forf. of <i>I.</i> (no corporation can plead usury).
Washington Ter.....	10	..	None.
West Virginia.....	6	..	Forf. of excess.
Wisconsin.....	7	..	Forf. of all the <i>I.</i>
Wyoming.....	10	..	None.

\* + no limit.

*Distinction of Simple and Compound Interest.* When a loan is made, it is usual to stipulate that the *I.* upon it should be regularly paid at the end of every year, half-year, etc. A loan of this sort is said to be at simple *I.* It is of the essence of such loan that no part of the *I.* accruing upon it should be added to the principal to form a new principal; and though payment of the *I.* were not made when it becomes due, the lender would not be entitled to charge *I.* upon such unpaid *I.* Thus, suppose \$100 were lent at simple *I.* at 5 per cent, payable at the end of each year; the lender would, at the end of 3 or 4 years, supposing him to have received no previous payments, be entitled to \$15 or \$20, and no more. Sometimes, however, money or capital is invested so that the *I.* is not paid at the periods when it becomes due, but is progressively added to the principal; so that at every term a new principal is formed, consisting of the original principal and the successive accumulations of *I.* upon *I.* Money invested in this way is said to be placed at *compound I.* It appears not unreasonable that when a borrower does not pay the *I.* he has contracted for, at the period when it is due, he should pay *I.* upon such *I.* This, however, is not allowed by law; nor is it allowed to make a loan at compound *I.* But this rule is often evaded by taking a new obligation for the principal with the *I.* included, when the latter becomes due. Investments at compound *I.* are also very frequent. Thus, if an individual buy into the funds, and regularly buy fresh stock with the dividends, the capital will increase at compound *I.*; and so in any similar case.

*Calculation of Interest.* *I.* is estimated at so much per cent per annum, or by dividing the principal into 100 equal parts, and specifying how many of these parts are paid yearly for its use. Thus, 5 per cent, or 5 parts out of 100, means that \$5 are paid for the use of \$100 for a year, \$10 for the use of \$200 for the same period, and so on. Many attempts have been made to contrive expeditious processes for calculating *I.* The

following is one of the best: Suppose it were required to find the interest upon \$172 for 107 days at 5 per cent. This forms what is called in arithmetical books a double-rule-of-three question, and would be stated as follows:—

$$\begin{array}{l} \$ \text{ days. } \$ \text{ days.} \\ 100 \times 365 : 5 :: 172 \times 107 = \text{the interest required.} \end{array}$$

Hence, to find the *I.* of any sum for any number of days at any rate per cent, multiply the sum by the number of days, and the product by the rate, and divide by 36,500 ( $365 \times 100$ ); the quotient is the *I.* required. When the rate is 5 per cent, or  $\frac{5}{100}$  of the principal, all that is required is to divide the product of the sum multiplied by the days by 7,300 ( $365$ , the days in a year, multiplied by 20). Five per cent *I.* being found by this extremely simple process, it is usual in practice to calculate 4 per cent *I.* by deducting  $\frac{1}{5}$ ; 3 per cent by deducting  $\frac{2}{5}$ ; 2 per cent by dividing by 2; 2 per cent by taking the half of 4, and so on.

In calculating *I.* upon accounts current, it is requisite to state the number of days between each receipt or payment, and the date (commonly the 31st of December) to which the account current is made up. Thus, \$172 paid on the 15th of September, bearing *I.* to the 31st of December, 107 days. The amount of such *I.* may, then, be calculated as above explained, or by the aid of tables.

The 30th June is, after the 31st of December, the most usual date to which accounts current are made up, and *I.* calculated. It is desirable, in calculating *I.* on accounts current, to be able readily to find the number of days from one day in any month to any day in any other month. This may be done with the greatest ease by means of the following table:—

TABLE FOR ASCERTAINING THE NUMBER OF DAYS FROM ANY ONE DAY IN THE YEAR TO ANY OTHER DAY.

Jan.	Feb.	March.	April.	May.	June.	July.	August.	Sept.	Oct.	Nov.	Dec.
1	32	60	91	121	152	182	213	244	274	305	335
2	33	61	92	122	153	183	214	245	275	306	336
3	34	62	93	123	154	184	215	246	276	307	337
4	35	63	94	124	155	185	216	247	277	308	338
5	36	64	95	125	156	186	217	248	278	309	339
6	37	65	96	126	157	187	218	249	279	310	340
7	38	66	97	127	158	188	219	250	280	311	341
8	39	67	98	128	159	189	220	251	281	312	342
9	40	68	99	129	160	190	221	252	282	313	343
10	41	69	100	130	161	191	222	253	283	314	344
11	42	70	101	131	162	192	223	254	284	315	345
12	43	71	102	132	163	193	224	255	285	316	346

19	50	78	109	139	170	200	231	262	292	323	353
20	51	79	110	140	171	201	232	263	293	324	354
21	52	80	111	141	172	202	233	264	294	325	355
22	53	81	112	142	173	203	234	265	295	326	356
23	54	82	113	143	174	204	235	266	296	327	357
24	55	83	114	144	175	205	236	267	297	328	358
25	56	84	115	145	176	206	237	268	298	329	359
26	57	85	116	146	177	207	238	269	299	330	360
27	58	86	117	147	178	208	239	270	300	331	361
28	59	87	118	148	179	209	240	271	301	332	362
29	...	88	119	149	180	210	241	272	302	333	363
30	...	89	120	150	181	211	242	273	303	334	364
31	...	90	...	151	...	212	243	...	304	...	365

By this table may be readily ascertained the number of days from any given day in the year to another. For instance, from the 1st of January to the 14th of August (first and last days included), there are 226 days. To find the number look down the column headed January, to No. 14, and then look along in a parallel line to the column headed August, you find 226, the

number required. To find the number of days between any other two given days, when they are both after the 1st of January, the number opposite the first day must, of course, be deducted from that opposite to the second. Thus, to find the number of days between the 13th of March and the 19th of August, deduct from 231—the number in the table opposite to 19 and under August—72, the number opposite to 13 and under March, and the remainder, 159, is the number required, last day included. In leap years, one must be added to the number after the 28th of February.

When *I.*, instead of being simple, is compound, the first year's or term's *I.* must be found, and, being added to the original principal, makes the principal upon which *I.* is to be calculated for the second year or term; and the second year's or term's *I.*, being added to this last principal, makes that upon which *I.* is to be calculated for the third year or term; and so on for any number of years. But when the number of years is considerable, this process becomes exceedingly cumbersome and tedious, and to facilitate it tables have been constructed, for which see pages 599 to 602.

The first of these tables (p. 599) represents the amount of \$1 accumulating at compound *I.*, at 2½, 3, 3½, 4, 4½, 5, and 6 per cent every year, from 1 year to 70 years, in dollars and decimals of a dollar. Now, suppose that we wish to know how much \$500 will amount to in seven years at 4 per cent. In the column marked 4 per cent, and opposite to 7 years, we find \$1.315931, which shows that \$1 will, if invested at 4 per cent, compound *I.*, amount to \$1.315931 in 7 years; and, consequently, \$500 will, in the same time, and at the same rate, amount to \$500 × 1.315931, or \$657.966. For the same purpose of facilitating calculation, the present value of \$1 due any number of years hence, not exceeding 70, at 2½, 3, 3½, 4, 4½, 5, and 6 per cent, compound *I.*, is given in the tables, pp. 600, 602. The use of these tables is precisely similar to the one above. Let it, for example, be required to find the present worth of \$500 due 7 years hence, reckoning compound *I.* at 4 per cent; opposite to 7 years, and under 4 per cent, we find 75.291781, the present worth of \$1 due at the end of 7 years; and multiplying this sum by \$500, the product is \$379.5589, the answer required.

#### ANNUITIES.

Under the head ANNUITY we have given a brief account of that kind of property when viewed merely as a subject of commerce. In the present article we propose to explain briefly the principles of annuities, and to furnish some tables for the solution of the cases which most commonly occur in practice.

When a sum of money is to be paid yearly for a certain number of years, it is called an annuity. The annuities usually met with are either for a given number of years, which are called *annuities certain*; or they are to be paid so long as one or more individuals shall live, and are thence called *contingent annuities*.

By the amount of an annuity at any given time is meant the sum to which it will then amount, supposing it to have been regularly improved at compound interest during the intervening period.

The present value of an annuity for any given period is the sum of the present values of all the payments of that annuity. Nos. III. and IV. of the subjoined tables represent the amount and present value of an annuity of \$1, reckoning compound interest at 2½, 3, 3½, 4, 4½, 5, and 6 per cent from 1 year to 70. The use of these tables are numerous, and they are easily applied. Suppose, for example, it were required to tell the amount of an annuity of \$50 a year for 17 years, at 4 per cent compound interest. Opposite to 17 (Table III. p. 601) in the column of years, and under 4 per cent, is 23.69751239, being the amount of an annuity of \$1 for the given time at the given rate per cent; and this multiplied by 50 gives \$1,184.8756195, the amount required.

Suppose, now, that it is required what sum one must pay down to receive an annuity of \$50, to continue for 17 years, compound interest, at 4 per cent. Opposite to 17 years (Table IV., p. 602), and under 4 per cent, is 12.16569888, the present value of an annuity of \$1 for the given time and at the given rate per cent; and this multiplied by 50 gives \$608.284943, the present value required.

When it is required to find the time which must elapse, in order that a given sum, improved at a specified rate of compound interest, may increase to some other given sum, divide the latter sum by the former, and look for the quotient, or the number nearest to it, in Table No. 1., under the given rate per cent, and the years opposite to it are the answer; thus, in what time will \$523 amount to \$1,087.2794, at 5 per cent. compound interest? Divide 1,087.2794, etc., by 523, and the quotient will be 2.0789, etc., which under 5 per cent in Table 1. is opposite to 15 years, the time required.

If it had been required to find the time in which a given annuity, improved at a certain rate of compound interest, would have increased to some given sum, the question would have

been answered by dividing, as above, the given sum by the annuity, and, looking for the quotient not in Table No. I., but in Table No. III., under the given rate per cent, it would be found on a line with the time required, thus: A owes \$1,000, and resolves to appropriate \$10 a year of his income to its discharge; in what time will the debt be extinguished, reckoning compound interest at 4 per cent? 1,000 divided by 10 gives 100; the number in Table No. III. under 4 per cent, and nearest to this quotient, is 93.8265, etc., opposite to 41 years, and the required time. Had the rate of interest been 5 per cent, the debt would have been discharged in somewhat less than 37 years. Of the abstract truth of the principle there cannot, indeed, be a doubt. But everything depends on the increasing sums annually produced being immediately invested on the same terms; and this, when the sum is large and the period long, is altogether impracticable.

Let it next be required to find an annuity which, being increased at a given rate of compound interest during a given time, will amount to a specified sum: in this case we divide the specified sum by the amount of \$1 for the time and rate given, as found in Table III., and the quotient is the answer. Thus: What annuity will amount to \$1,087,279.4 in 15 years at 5 per cent compound interest? Opposite to 15 years in Table III., and under 5 per cent, is 21 5785, etc., the amount of \$1 for the given time and rate; and dividing 1,087,279.4, etc., by this sum, the quotient, 50.887, etc., is the annuity required. *Deferred annuities* are those which do not commence till after a certain number of years; and *reversionary annuities*, such as depend upon the occurrence of some uncertain event, as the death of an individual, etc. The present value of a deferred annuity is found by deducting from the value of an annuity for the whole period the value of an annuity to the term at which the reversionary annuity is to commence. Thus: What is the present value of an annuity of \$50 to continue for 25 years, commencing at 7 years from the present time, interest at 4 per cent? According to Table No. IV., the value of an annuity of \$1 for 25 years at 4 per cent is \$15.62207,995, and that of \$1 for 7 years is \$9.60205,467, which being deducted from the other, leaves \$9.62002,528, which multiplied by 50 gives \$481, the answer required.

*Perpetual Annuities.* When an annuity continues payable, without termination, it is called a perpetual annuity, or perpetuity. Of the five quantities considered under the last head, two, namely, the amount and the time, fall necessarily to be discarded, as in perpetual annuities they become infinite, and consequently unassignable. The three quantities remaining to be noticed are, 1. the annuity; 2. the rate of interest; and, 3. the present value of the annuity, or the principal, which, being immediately laid out, will yield annually and perpetually a sum equal to the annuity.

The simple interest of any sum for a year being what may be produced annually by that sum, without increasing or diminishing it, must be evidently equal to the perpetual annuity of which such sum will be the present value. And as while the rate continues the same the annual interests produced by any two sums are to each other as the principals which produced them, it follows that at 5 per cent, 5 : 1 :: 100 : 100 ÷ 5 = 20; therefore, when the rate is 5 per cent, the value of the perpetual annuity is 20 years' purchase. In the same manner, when interest is at 4 per cent, 4 : 1 :: 100 : 100 ÷ 4 = 25; and the perpetual annuity is worth 25 years' purchase. And it follows, that in every case the value of a perpetual annuity may be found by dividing any sum by its interest for one year. This being premised, the solution of the three following cases becomes nearly self-evident.

*Annuity and Rate given, to find the Principal or Present Value.* *Rule.* Divide the annuity by the rate, and the quotient will be the principal or present value required. *Ex.* Required the value of an estate of which the yearly rent is \$1,500, reckoning interest at 3 per cent per annum.

$$\$1,500 \div .03 = \$50,000.$$

*Principal or Present Value and Rate given, to find the Annuity.* *Rule.* Multiply the present value by the rate, and the product will be the annuity. *Ex.* A gentleman purchases an estate for \$14,000; at what yearly rent must he let it in order to have 4 per cent per annum upon the price?

$$\$14,000 \times .04 = \$560.$$

*Principal or Present Value and Annuity given, to find the Rate.* *Rule.* Divide the annuity by the present value. *Ex.* An estate which cost \$5,000 is let for \$150 per annum; what rate of interest has the purchaser on the price?

$$\$150 \div \$5,000 = .03, \text{ or } 3 \text{ per cent.}$$

When, as is assumed throughout the present article, the interest is convertible into principal at the same terms as the annuity is payable, no difference arises in the valuation of perpetual annuities from the circumstance of the instalments being payable twice a year, as the annuity divided by the rate of interest for one year must always produce the same quotient as half the annuity divided by half the annual rate of interest.

For *Life Annuities*, see *LIFE INSURANCE*.

*Interim*, the mean-time; the interval between two periods.

*Interjoist*, a middle joist or cross-beam.

*Interlacing*, mixed or joined together.

*Interleave*, to place blank leaves of paper, in binding, between the printed leaves or sheets of a book.

*Interlineation*, additions or corrections made in manuscript between the previously written lines.

*Interlocution*, an intermediate act or decree before final decision.

*Interlude*, a farce or light piece performed at a theatre between the first play and the after-piece.

*Intermediate*, interposed, lying between.

*Internal Revenue*, that branch of the Treasury of the U. States whose object is to collect, in the form of internal duties, specific and *ad valorem*, taxes imposed on various kinds of manufactures, stamp duties, taxes on banks and bankers, etc. The laws of internal revenue of interest for manufacturers and traders are given in this work under the heads *BREWER* (for fermented liquors), *SPIRITS*, *STAMPS*, and *TOBACCO*.

The receipts from the several sources of taxation under the internal revenue laws for the years 1877 and 1878, are shown in the following table:—

Sources.	1877	1878.
Spirits .....	\$57,469,429.72	\$50,420,815.80
Tobacco.....	41,103,546.92	40,091,754.67
Fermented liquors .....	9,480,789.17	9,387,051.73
Banks and bankers .....	3,829,729.33	3,492,031.85
Penalties, etc .....	419,399.41	346,007.55
Adhesive stamps .....	6,450,429.15	6,380,405.13
Back taxes under repealed laws	233,230.55	429,653.71
Total .....	\$118,995,184.25	\$111,097,725.49

**International and Great Northern R.R.** runs from Longview to Houston, Tex., 236 m., and from Palestine to Austin City, 181 m.; with branches from Troupe to Minneola, 44.30 m.; from Phelps to Huntsville, 8 m.; and from Houston to Columbia, 50 m.; total, 519.30 m. This Co., whose offices are in Palestine, Tex., was formed by the consolidation, in 1873, of the Houston and Great Northern and the International R.R. Cos. In 1878 the road was, at the suit of the 2d mortgage bondholders, placed in a receiver's hands. The Co. has received from the State of Texas a land grant of 500,000 acres, which is vested by purchase in the Texas Land Co., of which the R.R. Co. holds 8,000 of the 10,000 shares. *Financial statement:* Cap. stock, \$5,500,000; funded debt, \$12,307,000; coupons overdue, funded, \$2,458,000, not funded, \$784,310. *Funded debt in detail:* 1st mortgage (International), issued 1871, \$3,264,000, payable 1911, interest 7% (Apr. and Oct.); 1st mortgage (Houston and Great Northern), issued 1872, \$4,084,000, payable 1900, interest 7% (Jan. and July); 2d mortgage (International), issued 1874, \$739,000, payable 1904, interest at 8% (Feb. and August); 2d mortgage (Houston and Great Northern), issued 1874, \$1,427,000, payable 1904, interest 8% (Feb. and Aug.); convertible (International), issued 1872, \$1,555,000, payable 1892, interest 8% (Feb. and Aug.); convertible (Houston and Great Northern), issued 1872, \$1,238,000, payable 1892, interest 8% (Feb. and Aug.).

**Interoceanic**, lying between two seas; a communication connecting two oceans,—as a railroad, a road, etc.

I.—Table showing the Amount of \$1 improved at Compound Interest, at 2½, 3, 3½, 4, 4½, 5, and 6 per cent, at the end of every year, from 1 to 70.

II. — Table showing the Present Value of \$1 receivable at the end of any given year, from 1 to 70, reckoning Compound Interest at  $2\frac{1}{2}$ , 3,  $3\frac{1}{2}$ , 4,  $4\frac{1}{2}$ , 5, and 6 per cent.

Years.	$2\frac{1}{2}$ per cent.	3 per cent.	$3\frac{1}{2}$ per cent.	4 per cent.	$4\frac{1}{2}$ per cent.	5 per cent.	6 per cent.

III. — Table showing the Amount of Annuity of \$1 per Annum, improved at Compound Interest, at 2½, 3, 3½, 4, 4½, 5, and 6 per cent at the end of each year, from 1 to 70.

Years.	2½ per cent.	3 per cent.	3½ per cent.	4 per cent.	4½ per cent.	5 per cent.	6 per cent.
1	1.00000,000	1.00000,000	1.00000,000	1.00000,000	1.00000,000	1.00000,000	1.00000,000

**Interpolate**, to add to an original; to alter a book or manuscript.

**Interpreter**, a linguist; a translator of languages in law courts, or for travellers, etc.; one who explains between two parties.

**Intersect**, to divide into parts; to meet and cross each other.

**Interspace**, a small intervening space; the space between one thing and another.

**Intertie**, horizontal timber framed between two posts.

**Interview**, a meeting of parties; a conference.

**Interweave**, to insert together; to intermix or unite in texture or construction.

**Intestate**, dying without having made a will.

**Intimation**, an indirect suggestion or notice given; a declaration or remark.

**Intoxicate**, to make drunk.

**Introduce**, to bring into notice or practice.

**Introduction**, a preface or preliminary dissertation to a book. — The act of bringing into a country. — Ushering an individual into the presence of another personally or by letter.

**Intruder**, one who forces his way in uninvited; one who enters a manufactory or place of business without permission previously obtained.

**Inulin**, a starch obtained from the dandelion and other plants.

**Invalid**, weak, worn out, or disabled. — Of no weight or cogency.

**Invalidity**, the absence of legal right; informality.

**Invalid's Chair**, a chair for wheeling out infirm or sick persons in the open air; or a chair capable of assuming and retaining any required position, from the erect to the prone.

**Invention**, the action or operation of inventing, or of finding out something new; the contrivance of that which did not before exist. *Invention* is the creation or construction of something which has not before existed; *discovery* is the making manifest something which has hitherto been unknown. Galileo invented the telescope; Harvey discovered the circulation of the blood. — The skill or ingenuity displayed in the contrivance of anything new.

**Inventor**, a contriver; a discoverer or maker of something new.

**Inventory**, a schedule or list of the goods, wares, and merchandise, credits, and assets of a merchant, made out in minute detail, each article being set down separately, and separately valued according to its then actual cash value; the whole list being then entered in a book called an inventory book. Some merchants make out inventories more frequently, but usually they are made out at the close of each year. — *T. McElrath*.

**Inverness**. See GREAT BRITAIN (Seaports).

**Investigation**, a searching inquiry.

**Investigator**, an examiner; one charged to look into anything, as the state of affairs of a company or firm.

**Investment**, money put out at interest in some public stock or association, or in the purchase of houses or land, etc.

**Invoice**, a mercantile document containing a description of goods sold or consigned, with an account of the charges, if any, that are made against the buyer or consignee. Inland *I.* are generally made out in the form of bills of parcels, containing in the title the place, date, and names of the parties. Shipping or exportation *I.* are usually headed with a short account of the goods, the names of the vessel and captain, the port of destination, the name of the consignee, and a specifi-

cation of the account on which the goods are sent. All exportation *I.*, whose total value is not under \$100, must be certified by an American consul.

An exportation *I.*, carelessly prepared, or worded without due regard to the requisites of the American custom-house regulations, is perhaps the most frequent source of difficulties in the entry of imported goods. Importers can easily guard themselves against the vexatious difficulties, harassing delays, and even losses, resulting from a defective *I.*, by giving careful attention to the *Consular Regulations relating to the Authentication of I.*, prescribed by the President of the U. States, Oct. 1, 1870, that we here give in full: —

All *I.* of importations from countries in which there are such officers, must, before shipment of the merchandise, be produced to and authenticated by the U. States Consular Officer nearest the place of shipment for the U. States. — By the place of shipment, is meant the place where the merchandise has been manufactured, finished, or finally prepared for exportation, and where the journey to the U. States commences; and is not necessarily the place where it is actually put on board ship. Countries adjacent to the U. States are excepted from the above rules. The authentication *there* may be by the Consular Officer at or nearest to the port or place of clearance for the latter. — All such *I.* must be triplicate; the three copies to be regarded as *one I.*, and subject to only one charge for consular certificate. — The authentication must be by certificate under the consular seal, and must be either indorsed on each copy of the invoice, or attached by tape, cord, or ribbon, passed under the seal in such manner as to secure integrity. The certificate must state that the *I.* has been produced to the officer certifying; also the date of such production, the name and identity of the person producing, and the intended port of destination of the merchandise in the U. States, as declared by such person. It is desirable that it should also, as far as practicable, indicate the facts in regard to market values at the principal markets of the country, of all merchandise the duty on which is in any respect or part based on such values. — The act of March 3, 1865, fully recognizes the solemnity of these certificates, and the importance of consular fidelity in regard to them; but Consular Officers are not to consider themselves authorized under its provisions absolutely to withhold their certificates, *even* when they believe the cost or market values set forth in the *I.* to be too low; but in such cases they will, on due investigation, certify on the *I.* what, in their opinion, is such true market value, and let the importer take the hazard of satisfying Customs Officers of the contrary. — To facilitate this, it is recommended that every *I.* should, upon its face, at the right-hand margin, have a blank column for "consular corrections of *I.*;" in which, when he deems it necessary, the Consul may enter in figures what he regards as the true values at the principal markets of the country, and certify accordingly, as set forth in Forms. — It is the duty of Consular Officers to acquaint themselves as thoroughly as possible with market values at the principal markets of their districts; with the weights, measures, tares, bounties, etc., there used; and in general with all requisites to enable them to certify intelligently. They may retain *I.* for a reasonable time for proper inquiry.

To judge correctly the market value of any given article, it will often be important to inquire carefully as to prices in sales thereof for other markets than our own. When the U. States are the principal consumers, and fictitious sales to create nominal values are detected, Consuls should ascertain the actual cost of production, and add the customary percentage for profits. In such cases especial care is enjoined as to certificates. — They will, in all proper cases, require samples of the merchandise to be deposited with them, especially when the invoice descriptions of merchandise are not specific and full enough to enable them, or Customs Officers, intelligently to judge of the market value without inspection of the merchandise itself. It is particularly enjoined upon Consular Officers at London, Manchester, Leeds, Glasgow, Belfast, Paris, Lyons, Zurich, Basle, Aix-la-Chapelle, Berlin, Leipzig, Dresden, Vienna, Frankfurt, and Brussels, *generally* to require samples of all merchandise imported from there, of a nature to be sampled. All samples must be accompanied by a card or statement, which, if practicable, shall be attached thereto, containing the particulars indicated on the Form prescribed by the Department, including the certificate at the bottom thereof, which must be signed by the shipper or his agent; and samples of textiles must be of such size as may be indicated by the proper revenue officer of the Treasury Department. All samples must be carefully preserved, together with the cards or statements accompanying them, and must not be suffered to be inspected or seen by others than officers or agents of the Government, except in cases of exhibition for the purpose of ascertaining or establishing the market value or price; in which case the name of the shipper will not be made known. — Every *I.* must be signed by the owners or shippers

of the merchandise invoiced, if the same has been actually purchased; or by the manufacturers or owners, if the same has been otherwise obtained; or, if in either case this is impracticable, then by a duly authorized agent. — It must, when produced to the Consul, be indorsed with a declaration signed by such purchaser, manufacturer, owner, or agent, setting forth (a) That it is in all respects true. (b) That no different *I.* of the articles therein mentioned has been, or will be furnished to anyone. (c) That it sets forth the actual quantity, respectively, of all articles therein named, which are subject to specific duty. (d) That as to all articles therein named, which are subject, either wholly or partly, to a duty based upon their value, and obtained by purchase, it contains a true and full statement of the time and place of purchase, their actual cost, and all charges upon them in the currency paid therefor; and when otherwise obtained, the actual market value thereof, respectively, at the principal markets of the country in which they were obtained or manufactured. (e) That no discounts, bounties, or drawbacks are contained in said *I.* but such as have been actually allowed. — This declaration on the part of the owner, manufacturer, purchaser, or agent, whether under oath or not, is the verification of the invoice before shipment, recognized and prescribed by the acts of March 3, 1863, and March 3, 1865, and must not be confounded with consular authentication. — The declaration should, if possible, be made by the actual owner, manufacturer, or shipper of the merchandise. No agent must be permitted to make this declaration, or otherwise verify the *I.*, without having first filed with the Consul a duly executed power of attorney, authorizing him to act for and bind his principal. — When a verification by oath or affirmation of the owner, shipper, manufacturer, or agent, is deemed necessary by the Consular Officer, the affiant may, in countries where an oath, to be of legal force, must be taken before a local magistrate, or other officer, take the same before any such officer. The language and form of the oath, if taken by foreigners, should be those of their country. For the authentication of a signature in these cases, the fee of two dollars, prescribed by the consular tariff, is to be charged. — Consular Officers are forbidden to be in any way interested in the fees, or to interfere with the selection of such magistrate, or other officer. They may, in their discretion, on points on which they are in doubt, examine experts and others, either on affidavit or orally, without charge or expense to the U. States Government. — One *I.* must not embrace merchandise shipped by two or more vessels. Every *I.* must truly state quantities in the weights and measures of the country or place from which the importations are made, without respect to those of the U. States, and should set forth the quantity by weight of all woollen, worsted, mohair, and mixed goods (excepting carpeting and bunting); also of cotton bagging, of crinoline, corset, and hat steel wire, and the quantity by weight, measure, or tale, respectively, of all other goods the duty of which is estimated partly on either weight, measure, or tale. — When the value of a foreign currency mentioned in the invoice is not fixed by U. States laws, as set forth in the "Table of Equivalents," or shall have depreciated, or have been debased subsequently to the passage of such laws, the invoice must be accompanied by a consular certificate, showing the value of such currency in U. States silver dollars. No such certificates are required as to invoices of Swiss goods, made out in the *franc federal*; the franc of France being the standard value thereof. — The Consular Officer must return one of the triplicates to the person producing them; file one in his office for careful preservation; and, as soon as practicable, transmit the remaining one directly to the collector of the port of destination of the merchandise, either by the master of the vessel in which shipment is made, or by mail, and without the intervention of any party in interest. — If a Consular Officer ascertains and has reliable evidence of the falsity of an oath, administered either by himself or by a local magistrate whose certificate he has authenticated, he should notify the Treasury Department; which will transmit to him the original *I.* and oath, to be used, if deemed expedient, in a prosecution for perjury. He should also promptly inform the Treasury Department, and the collector of the port to which goods may be destined, of all errors and frauds discovered in *I.* that have been certified by him.

#### CERTIFICATE TO INVOICE.

*Foreign owner's oath. where goods, wares, or merchandise have been actually purchased.*

I, \_\_\_\_\_, do solemnly and truly swear, that the goods, wares, or merchandise described in the Invoice now produced, and hereunto annexed, were actually purchased for my account, or for account of myself and partners in the said purchase; and that said invoice contains a true and faithful account of the actual cost thereof, and of all charges thereon; and that no discounts, bounties, or drawbacks, are contained in the said invoice but such as have been actually allowed on the same.

Sworn to and subscribed before me, at \_\_\_\_\_, the \_\_\_\_\_ day of \_\_\_\_\_ A. D., 18\_\_\_\_, and of the independence of the United States the \_\_\_\_\_; and I do further certify, that I am satisfied that \_\_\_\_\_, who subscribes the foregoing oath, is

the person he represents himself to be; that he is a credible person; and that the statements made by him under said oath (or affirmation, as the case may be) are true.

[L. S.]

U. S. Consul.

#### CERTIFICATE TO INVOICE

*Foreign manufacturer or owner's oath, in cases where goods, wares, or merchandise have not been actually purchased.*

I, \_\_\_\_\_, of \_\_\_\_\_, do solemnly and truly swear, that the invoice now produced, and hereunto annexed, contains a true and faithful account of the goods, wares, or merchandise therein described at their market value at \_\_\_\_\_, at the time the same were (procured or manufactured, as the case may be), and of all charges thereon; and that the said invoice contains no discounts, bounties, or drawbacks, but such as have been actually allowed.

Sworn and subscribed before me, at \_\_\_\_\_, the \_\_\_\_\_ day of \_\_\_\_\_ A. D., 18\_\_\_\_, and of the independence of the United States of America the \_\_\_\_\_; and I further certify, that I am satisfied that \_\_\_\_\_, who subscribes the foregoing oath, is the person he represents himself to be; that he is a credible person; and that the statements made by him under said oath (or affirmation, as the case may be) are true.

[L. S.]

U. S. Consul.

**Invoice-Book**, the book in which are copied or posted the originals of bills and invoices of merchandise purchased or received.

**Involved**, embarrassed by debts or liabilities.

**Iodine**, an elementary substance obtained by a chemical process from kelp, from soap-makers' black ash, or from the residuary kelp-liquor of the soap-boilers. It is soft and friable, of a bluish-black color, and metallic lustre, sp. gr. 4.946. It is extremely volatile. Its smell resembles that of diluted chlorine; its taste is acrid. It is slightly soluble in water, but dissolves readily in ether, alcohol, and in the aqueous solutions of hydriodic acid and of iodide of potassium. With starch, free *I.* produces a beautiful blue color, so that a solution of starch gives the best test for its presence. If the presence of a soluble iodide is suspected, a small quantity of chlorine-water added displaces the *I.* from combination, and renders it capable of acting upon the starch. It is said that *I.* may thus be detected when dissolved in one million parts of water. *I.* combines with hydrogen to form *hydriodic acid*, and with oxygen to form *iodic acid*. If finely powdered *I.* is put into caustic ammonia, it is in part dissolved; the remainder is left as a dark powder, the *iodide of nitrogen* which, on being separated by a filter and dried on bibulous paper, forms an exceedingly explosive compound, a slight jar or the touch of a feather being sufficient to explode it. *I.* forms compounds with many of the metals, some of which are remarkable for their brilliant colors, and others are of great value in the arts and in medicine. *I.* and most of its compounds are irritant poison. — *Imp. duty*: crude, free; resublimed, 75 cts. per lb.; salts of, 15 per cent.

**I. O. U.** (I owe you), an acknowledgment or indebtedness for money or goods lent.

**Iowa**, a Western State of the American Union, situated between lat. 40° 20' and 43° 30' N., lon. 90° 12' and 96° 38' W. It is bounded N. by Minnesota, E. by the Mississippi, which separates it from Illinois and Wisconsin, S. by Missouri, and W. by the Missouri and Big Sioux Rivers, which separate it from Nebraska and Dakota. Greatest length from E. to W., 307 m.; greatest breadth, 196 m.; area, 55,045 sq. m. The State is divided into 99 counties. Des Moines, its capital, is a thriving city, situated at the head of navigation of the Des Moines River, 300 m W. of Chicago; pop. 20,000. The other principal cities of *I.* are: Burlington (pop. 25,000); Cedar Rapids (8,000);

Clinton (8,000); Council Bluffs (12,000); Davenport (25,000); Dubuque (26,000); Iowa City (8,000); Keokuk (14,000); Muscatine (8,500); Ottumwa (7,000); Waterloo (6,000). The total pop. of *I.*, which was 43,112 in 1840, 192,214 in 1850, 674,913 in 1860, and 1,194,020 in 1870, is now about 1,500,000.

The surface of *I.* is somewhat elevated and generally undulating. It has no mountains, nor even hills, of any great height. Table Mound, a conical elevation with a flat summit, three or four miles from Dubuque, is about 500 feet high. On the borders of the rivers there are frequent "bluffs," which are generally from 40 to 130 feet high. The highest ground in the State is a plateau in the N. W., called *Coteau des Prairies*, which enters it from Minnesota. The S. part of the State abounds with grassy lawns and verdant plains, intersected by numerous rivers, the chief of which are the Des Moines, the

FIG. 287. — SEAL OF IOWA.

Skunk, the Iowa, and the Red Cedar (a branch of Iowa) Rivers, which flow into a S. E. direction into the Mississippi. The banks of almost all of these rivers are skirted with belts of wood. The distinguishing feature, however, of *I.* is its unique and admirably diversified prairies, sometimes spreading out into vast plains. From the scarcity of wood, the scenery becomes wearisome and tame. In the N. part, however, the surface is more elevated, the tops of hills are covered with towering oaks, and the rivers tumble over precipitous ledges and craggy rocks. The soil of *I.* is generally fertile, and of easy cultivation, and no State in the Union has a smaller proportion of inferior land. The climate is generally healthful, and highly favorable for agricultural operations. The peach generally blossoms in mid April, and wheat ripens early in August. The winter is occasionally severe, but the severity is not so great as is usual in the same latitude. The summer, also, is less oppressively hot. *I.* is essentially an agricultural country. Its fine prairies and rich natural pastures afford peculiar facilities for raising cattle and sheep. It produces more wheat than any other State in the Union, stands only second to Illinois in the production of Indian corn, and ranks third in the production of oats. Its climate and soil are also well adapted for the cultivation of flax, tobacco, castor-oil plant, etc. The relative value of its agricultural products is given in this work under the name of each of the principal crops. The raising of hogs is very extensive, and was a profitable occupation down to 1877, when the diseases of swine, the principal of which is called hog cholera, caused to breeders and farmers of *I.* a loss of nearly \$3,500,000. There has been since but little abatement of the disease. The hogs packed in *I.* in 1877 amounted to 419,442; in 1878, to 496,850. In 1879 the State contained 15,541,793 acres of improved land on a total area of 35,228,800 acres. The total area in woodland was 4,985,638 acres, of which 2,524,793 were included in farms. — The minerals of *I.* are not of great variety. The vast bituminous coal-field of the State occupies most of its central and southern portions. For upwards of 200 miles the River Des Moines passes through this great deposit, the area of which has been estimated at about 20,000 sq. m., embracing a country equal in extent to more than one half of the State of Indiana. The beds of coal, which are 100 feet in thickness, lie near the surface, and may be worked at small expense. The lead-mines of *I.* are a continuation of those of Illinois and Wisconsin; they are very rich. The only ones which have been worked are near the Mississippi, chiefly in the vicinity of Dubuque, and yield about 70 per cent of lead. — According to the last census the total number of manufacturing establishments in *I.* was 6,566, having 899 steam engines of 25,238 horse-power, and 726 water-wheels of 14,249 horse-power, and employing 25,032 hands. The capital invested amounted to \$22,420,183; wages paid during the year, \$6,393,292; value of materials, \$27,682,096; products, \$46,534,322, in which total flouring and grist mill products entered for \$15,635,345. *I.* exports a considerable quantity of agricultural and mining products through the Atlantic and Gulf ports. Its shipping points are Burlington, Clinton, Davenport, Dubuque, Fort Madison, Keokuk, Muscatine, etc. The State has three U. States ports of delivery, Burlington, Dubuque, and Keokuk. In 1879, *I.* had 76 national banks in operation, with an aggregate paid-in capital of \$5,927,000. There were, besides, 287 savings-banks and private bankers, having an aggregate capital of \$5,255,013. — The amount of public land that has been approved and certified to the State of *I.* under the several grants of Congress is 8,000,000 acres, or nearly one fourth of the entire State. Of this amount, the State has conveyed to railroad companies, counties, and in-

dividuals entitled thereto, about 6,000,000 acres, leaving about 2,000,000 acres to be conveyed in the future. — The railroad system of *I.* has progressed with astonishing rapidity; the total mileage of main track having increased from 655 in 1860 to 4,265 in 1879. To this day the working of these roads has not been remunerative, which is partly owing to lavishness of expense in their construction. In 1879 the aggregate debts of the *I.* railroads were estimated at \$64,744,418, or \$15,574.80 per mile. The stock and debt amounted to \$153,601,784, or \$36,349.80 per mile. The following table exhibits the names of the lines lying wholly or partly within the State, the number of miles completed in *I.* in 1879, and the entire length of the lines: —

Names of Companies.	Length of Line.	Length of Line in Iowa.
	Miles.	Miles.
Burlington, Cedar Rapids, and Northern	412.33	402.27
Burlington and Northwestern	19.80	19.80
Burlington and Northwestern	142.34	79.00
Cedar Falls and Minnesota	75.53	75.53
Cedar Rapids and Missouri River	274.20	274.20
Central Railway of Iowa	190.64	190.64
Chicago, Burlington, and Quincy	1,283.75	506.28
Chicago, Clinton, and Western	208.10	183.20
Chicago, Clinton, Dubuque, and Milon	10.00	10.00
Chicago, Iowa, and Nebraska	82.40	82.40
Chicago, Milwaukee, and St. Paul	1,612.23	434.00
Chicago, Rock Island, and Pacific	635.96	446.25
Crooked Creek	8.00	8.00
Dakota Southern	61.50	5.83

Toledo and Northwestern	3.00	3.00
Waukon and Mississippi	23.00	23.00

**Iowa Falls and Sioux City R.R.** runs from Iowa Falls to Sioux city, Ia., 183.69 m. This Co., whose offices are in Cedar Rapids, Ia., opened the road in 1870, and leased it from its opening to the Illinois Central R.R. Co., for the net earnings and a drawback of 10% on all business to and from their line passing over the Dubuque and Sioux City R.R.; also a rental from the Sioux City and St. Paul R.R. Co. *Financial statement:* Cap. stock, \$4,625,000; funded debt \$2,952,000, consisting of 1st mortgage bonds, issued in 1869, payable in 1917, interest 7% (April and October).

**Iowa Midland R.R.** runs from Lyons to Anamosa, Ia., 68.80 m. This Co., whose offices are in Chicago, is controlled by the Chicago and North-Western R.R. Co., which indorsed and sold the bonds. *Financial statement:* Cap. stock, \$44,947.50; funded debt, \$1,350,000, consisting of 1st mortgage 8% bonds issued in 1870, payable in 1900, guaranteed principal and interest by the Chicago and North-Western R.R. Co.

**Iowa Southern and Missouri Northern R.R.** runs from Washington, Ia., to Leavenworth, 270.45 m., with the following branches: Des Moines to Indianola, Ia. (originally the Des Moines, Indianola, and Missouri R.R.), 21.40 m.; Sumner to Winterset, Ia. (originally the Des Moines, Winterset,

set, and South-Western R.R.), 26.50 m.; and the Atchison Branch, Chicago, and South-Western R.R., 29.08 m., making a total of 347.43 m. of road. The Missouri Kansas Bridge and the Fort Leavenworth R.R., both owned by separate Cos., but controlled by stock held by the Chicago, Rock Island, and Pacific R.R. Co., are included in the main line of this Co. This Co., whose offices are in Chicago, Ill., leased the road in perpetuity to the Chicago, Rock Island, and Pacific R.R. Co., which guarantees \$3,000,000 of bonds, and holds nearly all the stock.

Fig. 233.—IPECACUANHA.

*Financial statement, 1878:* Cap. stock, \$3,200,000; funded debts, \$5,000,000, consisting of 1st mortgage 7% bonds issued in 1869, payable in 1890, guaranteed by the Chicago, Rock Island, and Pacific R.R. Co. Interest on bonds paid as rental, \$350,000.

**Ipecacuanha**, a medicinal root derived from several plants growing in S. America. The best is the annulated, yielded by a small shrubby plant, *Cephaelis ipecacuanha* (Fig. 228), found in moist situations in Brazil and Colombia. It occurs brown, red, and gray, or grayish-white. This kind, sometimes called Brazilian or Lisbon ipecacuan, is exported from Rio Janeiro in bales and barrels. The root is in short pieces, of the thickness of a goose-quill, with numerous circular depressions or clefts, and much twisted; and having a central woody fibre, surrounded by a cortical part, in which its virtues chiefly reside; the larger, therefore, its relative proportions the better. Another kind, black and weaker, the product of the *Psychotria emetica*, a native of Peru, is sometimes exported from Carthagena. The primary effect of *I.* is that of stimulating the stomach. If the dose be sufficiently large, it acts as an emetic, a purpose for which it is much employed. *Imp.* free.

**Ireland.** See GREAT BRITAIN.

**Iridioscope**, an optical instrument which shows the inside of the eye.

**Iridium**, a rare, brittle, whitish metal, found in combination with platinum and osmium. When carefully polished it resembles platinum. Being a very hard substance, it is used for tipping or pointing metallic pens. The value of *I.* is about \$2 per gramme. *Imp.* free.

**Iris.** See ORRIS-ROOT.

**Irish-Moss.** See CARRAGEEN.

**Irlanda** [Sp.], fine Irish linen.

**Iron** [Fr. *fer*; Ger. *Eisen*; It. and Por. *ferro*; Sp. *hierro*]. *I.* and coal, it has been well said, are kings of the earth. No substance can indeed be named, possessing so many useful qualities, and capable of such a variety of applications, as *I.*, this most common of metals. It is of bluish-white color, and when polished has a great deal of brilliancy. It has a styptic taste, and emits a smell when rubbed. Its hardness exceeds that of most other metals; and it may be rendered harder than most bodies by being converted into steel. Its sp. gr. varies from 7.6 to 7.8. It is attracted by the magnet or loadstone, and is itself the substance which constitutes the loadstone. But when *I.* is perfectly pure, it retains the magnetic virtue for a very short time. It is malleable in every temperature, and its malleability increases in proportion as the temperature augments; but it cannot be hammered out nearly as thin as gold or silver, or even copper. Its ductility is, however, more perfect; for it may be drawn out into wire as fine at least as a human hair. Its tenacity is such that an *I.* wire 0.078 of an inch in diameter is capable of supporting 549.25 lbs. avoirdupois without breaking. To enumerate the various uses of *I.* would require a lengthened dissertation. No one who reflects for a moment on the subject can doubt that its discovery has been of the utmost importance to man; and has done more, perhaps, than anything else to accelerate his advance in the career of improvement. It is capable of being cast into moulds of any form, of being drawn into wire of any desired length or fineness, of being extended into plates or sheets, of being bent in every direction, of being sharpened, or hardened, or softened at pleasure. *I.* accommodates itself to all our wants and desires, and even to our caprices. It is equally serviceable to the arts, the sciences, to agriculture, and war. The same ore furnishes the sword, the ploughshare, the scythe, the pruning-hook, the needle, the graver, the spring of a watch or of a carriage, the chisel, the chain, the anchor, the compass, the cannon, and the bomb. *I.* is used in medicine as a reconstructive tonic. Among its numerous medicinal preparations in use are metallic *I.*, a grayish powder; protocarbonate of *I.*, in pills and mixtures; sulphate of *I.*; hydrated oxide of *I.*, also called subcarbonate; tincture of the chloride of *I.*; wine of *I.*; tartrate of *I.* and potassa; phosphate, lactate, and iodide of *I.*; citrate of *I.* and quinia; perchloride of *I.*; ferric alum, etc. There are many varieties of *I.*, distinguished in the arts by particular names, but all of them may be reduced under one or other of the three following classes: *cast* or *pig I.*, *wrought* or *soft I.*, and *steel*. *I.* is so widely diffused that almost every mineral contains some of it, and it is a chief constituent of a great many. It is not absent from the organic kingdom, and in the blood of all vertebrate animals occurs in notable proportions. It is not a little remarkable that while this commonest of metals is never found in the metallic state amongst terrestrial minerals, the aerolites, or meteoric stones, which fall upon our planet from out of the realms of immeasurable space, consist usually of little less than metallic *I.*, alloyed with a little nickel.

#### IRON ORES.

The minerals which yield *I.* are plentiful and easily obtained, but in them not a particle of *I.* exists in a metallic state, the metal being combined with oxygen and other bodies, so that

all the properties of the simple substance are entirely disguised. The richest and most valuable ores of *I* are oxides, such as the magnetic oxides, or magnetite, hematite, red hematite, specular *I*, etc. Ores are rarely used which contain less than 25 per cent of *I*, and they may be roughly divided according to their richness into *poor ores*, those between 25 and 35 per cent; *ordinary or average ores*, between 35 and 50 per cent; and *rich ores*, those containing more than 50 per cent of metallic *I*.

In the abundance, purity, and wide distribution of *I* ores, and their accessibility to the largest coal areas in the world, the U. States possesses facilities for an iron industry unexcelled by those of any other land. Along the eastern coast the magnetic ores are found as an almost constant associate of the older

great size, in some cases nearly 200 feet in thickness of solid ore. These ores often contain large proportions of titanic acid, sometimes from 12 to 30 per cent, which renders many deposits of little present value. Phosphorus and sulphur, especially the former, are quite generally present, and often in a damaging proportion. In the highlands of E. New York, and portions of the adjoining State of Massachusetts, in the same belt of metamorphic rocks, valuable deposits of magnetite also occur, which are of special importance in Orange, Putnam, and Dutchess Counties. — In direct continuation of these deposits are those of the N. counties of New Jersey, Passaic, Sussex, Morris, and Warren, a belt of this same series passing across the State from N. E. to S. W., and contains some of the most valuable ores of the E. United States. In this region is also included the unique deposit of Franklinite, a manganiferous magnetite containing zinc, which is of great importance in the production of zinc and manganiferous pig-*I*, or spiegeleisen. The ores W. of the Hudson, in New York and N. New Jersey, have been wrought from a very early period, and contain but little or no titanium, but are commonly contaminated by sulphur or phosphorus, generally to so great an extent as to unfit them for the manufacture of steel-iron. — In Pennsylvania the only really important deposits of magnetite are found in the S. E. part of the State, at Cornwall, in Lebanon County, where they occur near the junction of the Mesozoic sandstone and metamorphic Silurian slates. They are quite sulphurous, and are associated with copper minerals, but particularly free from phosphorus, and are altogether one of the finest and most important deposits in the country. In other places in E. Pennsylvania magnetites are found, and are remarkable often for an association with chrome and alumina. — Following this Archaean belt of the Appalachian Mountains, through Maryland and Western Virginia, magnetites occur in numerous places, but their importance is not yet fully known. — In W. North Carolina they have been fully investigated, and occur in an abundance and of a purity unsurpassed by any other of the well-known regions of the country. They are found in several nearly parallel belts, passing across the W. part of the State in a S. W. direction into N. Georgia, where they still retain considerable importance. Some of the North Carolina ores are quite titaniferous, others aluminous or chromiferous, while others again are of very exceptional purity, as the celebrated Cranberry ore of Mitchell County. These ores are found often in beds of 300 or 400 feet in width, and are destined to assume a great value in the development of the *I* industry of that region, especially as they are not far distant from the valuable extensions of the Alleghany coal-field in the Cumberland region of W. Tennessee, the Black Warrior basins, etc., of Alabama, and the Deep and Dan Rivers Triassic coal-fields of North Carolina. These magnetites of the E. United States flank the great Alleghany coal-basin along its entire E. margin, and must form the most important store-houses of ore for the *I* industry of that part of the country. — Bearing a similar though more remote relation to the N. W. margin of the Alleghany coal-basin and the coal-fields of the Mississippi Valley in Indiana, Illinois, Missouri, etc., are the rich specu-

Fig. 289. — BLAST FURNACE.

metamorphic rocks, the gneiss, hornblende, and mica schists of the Appalachian Mountains, in nearly continuous lines of outcrop from the borders of the St. Lawrence River and Lake Champlain in N. New York, to their terminations in the N. part of Georgia. The ore occurs in beds interstratified with the other members of the Archaean system, following the severe contortions of that series, usually in lenticular-shaped deposits, and though limited in extent and thickness, are often of great magnitude. The thickness is subject to very great variations, and, while sometimes occurring in beds 150 to 200 feet thick, they are usually of much less size. In the character of the ores, the mode of occurrence, and their associations, they bear a very close resemblance to the magnetic deposits of Sweden. — In N. New York in the Adirondack Mountains, in Essex and Clinton Counties, immense beds are found, which have long been worked, and supply much of the ore consumed in E. New York and on the Hudson River. The great beds of the Moriah district in Essex County are remarkable for their

lar hematites of Missouri and Lake Superior. The specular ores of Lake Superior, admitted in certain localities with magnetite, are found on the S. shore of Lake Superior beginning about ten miles from the lake in Marquette County, Michigan, and extending thence in a belt about 8 miles in width, in a south and westerly direction, into Northern Wisconsin. Developments, however, have only been made extensively in Marquette County, Michigan. The ore occurs in distinct beds in the metamorphic rocks of the Huronian age, which are chiefly quartzites, chlorite rocks, ferruginous schists, etc., in which the ore is often only a ferruginous stratum, rich enough to be valuable as an ore of *I*. These beds are of great magnitude, in some instances 200 feet or more in thickness, and not unrequently occur in lenticular masses, as mentioned when referring to the magnetites of the E. United States. The ore varies from a very pure specular ore, often beautifully crystallized in lamellae, to a siliceous ferruginous rock, of little value as an ore; and on the whole the ores are generally siliceous, and

often contain much jasper. The ore is otherwise exceptionally pure. According to their richness, they are divided into three classes: 1st, containing 55 to 65 per cent of *I.*; 2d, those containing 45 to 55 per cent; and 3d, those below 45 per cent of *I.* The ore is mined almost entirely in large open quarries, and since the first openings in 1856 they have produced about one quarter of the pig-*I.* made in the entire U. States. The great deposits of specular ore in Missouri occur in isolated peaks, or islets, of the older Archæan rocks, probably of the same age as the very similar ores of Lake Superior, surrounded by the more recent sedimentary rocks. They are situated about 75 m. S.W. of St. Louis, and appear in two principal localities, removed from each other by only a few miles, — Pilot Knob and Iron Mountain. Adjoining Pilot Knob are Cedar Hill, Shephard Mountain, etc., which are also ore-bearing. In both these localities the characteristic associate of the ore is a porphyritic rock, which is usually very much decomposed. The Pilot Knob deposits form a regular bed, distinctly stratified, while the Iron Mountain ore is of a compact character, and is found in veins in the porphyry more or less irregular. The ores of both localities have much of the character and purity of the Lake Superior ores, though the Pilot Knob ores are much more silicious than the Iron Mountain. From the purity of the Lake Superior and Missouri hematites, they afford the main source of supply in the U. States for making *I.* for conversion into steel by the Bessemer process, and for this purpose they are very largely used. They are the main dependence of the *I.* industry in W. Pennsylvania, Ohio, and the Mississippi Valley, and in the coals of these regions the Lake Superior ores first meet an abundant supply of fuel, in which they are deficient at home. Magnetic ores have been found in the Archæan rock of Wyoming Territory, Arkansas, etc., but they have not yet become an element in the *I.* industry of the country. The next ore of importance in the U. States is the "fossil" ore, an oolitic red hematite, which is found as a member of the Clinton group in the lower Silurian formation, and is known in different sections as the *Clinton fossil, dyestone, and flaxseed* ore. In the extent of its distribution, and the uniformity of its character and occurrence, it is one of the most remarkable ores in the country. Following the formation wherever it outcrops, it is found in almost a continuous stratum over a very large area of the Eastern U. States. In Dodge County, Wisconsin, it occurs as a bed 20 to 25 feet in thickness, of a soft gravelly character, and is there mined and known as flaxseed ore. Its next place of appearance is where the enclosing formation enters New York State at Little Solus Bay, from which it passes E. in a curved line through Oneida and Wayne Counties, and S. into Pennsylvania at Danville. It is mined and largely used in New York State, where it is familiarly known as the Clinton or Wayne County ore. From Danville, Pa., it passes S., through Huntingdon and Bedford Counties, and following the flanks of the Alleghenies it is found in all the intermediate States, disappearing finally in N. Alabama. At Danville and numerous other places in E. Pennsylvania and in Maryland it is very extensively worked, and known as the fossil ore. In E. Tennessee and in N. Alabama, as the dyestone ore, it forms a very important element in the *I.* industry of that region. The ore occurs as distinct strata in the Clinton group, usually in two beds, and though varying considerably, is on an average from 2 to 4 feet in thickness. The character of the ore is peculiar, being an aggregation of grains of peroxide of *I.*, each seeming to have a nucleus of some organic remains, and the mass is filled with fossils, and usually calcareous. It is probably the result of a deposition in shallow water in a manner similar to the accumulation of bog ore at the present day, and not a formation subsequent to that of the enclosing strata. Where, however, the beds have been highly tilted, the ore is not unfrequently found changed by the percolation of atmospheric waters into a brown hematite or hydrated oxide. The ore very generally contains considerable phosphoric acid from 0.5 to 1.00 per cent, and the pig-*I.* produced is wholly unfit for steel purposes and generally the better qualities of wrought-*I.*, yet it fulfils excellently well foundry purposes and the ordinary grades of malleable *I.* The ores of the coal measures of the U. States are much less abundant and important than those of Great Britain, and while valuable, are insignificant when compared with the richer and more commonly used ores already mentioned. In the Alleghany coal-fields no important deposits are found in the anthracite basins, and, though some local accumulations of argilliferous ore are found at the base of the upper group of coals, as the Oliphant ore, etc., of S. W. Pennsylvania and N. W. West Virginia, the chief deposits occur in the rocks of the lower group of coals. Several horizons in the lower coals in the western part of the Alleghany coal-field are peculiarly marked as ore-bearing, especially that of the *ferriferous limestones* of N. W. Pennsylvania and E. Ohio, and, while they are of some considerable value in N. W. Pennsylvania, they become of particular importance in the Hanging Rock region of S. Ohio, and E. Kentucky, where they are the foundation of a large industry. The ore resting upon a limestone is a carbonate of *I.*, more or less calcareous and argillaceous, though it appears more largely as a hydrated peroxide, the result of the decomposition of the original bed. Near the same horizon are also other deposits, of less interest, of nodular clay ironstone. In the Kanawha Valley of West Virginia important accumulations of ore are

also found in the lower coal series, which are not yet, however, an essential element in the manufacture of iron in that region. At many horizons in the Alleghany coal-basin deposits of argillaceous shale occur including scattered kidneys or nodules of clay ironstone, but they are of very uncertain character and are rarely of any importance as ores. The coal-fields of the Mississippi Valley have nowhere been found to contain any considerable deposits of *I.* ore. Black band *I.* ores have been found in the Triassic coal-basin of North Carolina, but Dr. Genth reports them to be valueless as ores, from the large proportion of phosphorus present, derived from fossil organic remains. At Pottsville, Pa., black band occurs metamorphosed by the same action that changed the accompanying coal into anthracite, but the deposits have not been found to be of great extent. The only important deposit of black band known in the U. States is in the coal measures of E. Ohio, where it exists as a local accumulation at the top of the lower series of coals, in limited portions of Stark and Tuscarawas Counties. The deposit varies greatly in thickness and character, and, while ranging from 6 to as high as 16 feet, the average thickness is about 12 feet, though it not unfrequently thins out entirely, or passes into a nonferrous bituminous clay shale. The ore is generally less rich than the Scotch black band, and contains 25 to 40 per cent of iron. — The only deposits of crystallized carbonate or spathic *I.* ore known in the U. States are found at Roxbury, Conn., and in S. Vermont, but they are of little economic significance. The brown hematites or limonites of the U. States are very widely distributed, and are of great interest in the *I.* industry of the country, and, while every State contains some deposit of them, they are particularly abundant in the valleys and lowlands along the flanks of the Alleghany Mountains, which are so rich in magnetic ores, and in similar relations, though in less extent, to the great ore deposits of Missouri and Lake Superior. These ores are largely used in the Eastern States as mixtures with the richer crystalline ores, and the deposits of S. Vermont, Salisbury, Conn., New York, and at other places, are well known, and contribute largely to the *I.* industry of that region. In E. Pennsylvania they are very abundant, and at numerous other places in the S. extension of the Alleghany Mountains, in Tennessee, etc., but, from the great uncertainty of the extent of the deposits, they rarely can prove the basis alone of any important *I.* industry in our country. — The Laurentian rocks of Canada are very rich in magnetic ore, similar in character to those of N. New York. The area including them stretches in direct continuation of the Adirondack region on the N. side of the St. Lawrence River in a N. W. direction, crossing the river about Ogdensburg, and passing in a broad area along the E. shores of Georgian Bay and Lake Superior. The ore occurs in numerous deposits, similar in character to those of E. New York, and often of great dimensions, as the celebrated bed of Marmora, which is 100 feet in thickness. They have been mainly developed in the vicinity of the Rideau Canal, Marmora, Belmont, etc., in the region N. of Kingston, from which they have been shipped to some extent to the *I.* centres of Pennsylvania and Ohio. Though selected ore of a fair degree of purity is obtained, it is generally largely contaminated with sulphur and phosphorus, and often contains very large proportions of titanium. But while Canada contains very extensive deposits of ore, from the absence of mineral fuel it produces but a very small amount of *I.* The immense deposits of magnetite, specular, and other ores which are found in the U. States, and the facilities which our mode of transportation gives to their union with the great coal areas of the Alleghany and the Mississippi, must give to the U. States the foremost position in the future *I.* industry, and consequently of the manufacture of the world. In their development we are yet but beginning to realize their importance, and the future must witness great advances in the manufacture in the Eastern States, but more particularly in the Virginias, E. Tennessee, N. Alabama, and in W. North Carolina, which are so abundantly provided with rich and pure ores. The manufacture of *I.* in the Eastern States will undoubtedly be divided into two great regions, the northern centring in Pennsylvania, and the southern in adjoining corners of Alabama, Georgia, Tennessee, and North Carolina. Independent, however, of these regions in the E., the facilities offered by the valley of the Mississippi, in its valuable coal-basins, and the rich ores of Missouri and Lake Superior, must surely give materials to large *I.* industries, and all the attendant manufactures, and the rich and fertile valley of the Mississippi must be the home of a large, wealthy, and, from its position, a united population.

#### MANUFACTURE.

It is not definitely settled how far *I.* was used in ancient times, but it is certain that if it was known at all it must have been obtained directly from the oxides by the simple process of heating the ore with charcoal in a small furnace or on a hearth, the necessary temperature being obtained by urging the fire with some rude blowing apparatus. In localities where the nature of the ore is suitable and fuel abundant, malleable *I.* is still obtained from the ore by a single process, as in our old bloomery forges. But the largest amount by far of *I.* produced in all civilized countries is now obtained in the state of cast-*I.* by the process of *smelting*.

In this process the ore is roasted after having been broken up into lumps. The operation is performed by spreading alternate layers of coal and ore to a height of 10 ft., and then setting fire to the fuel at one end of the mass. The combustion spreads gradually through the heap, but some months elapse before it is completed. The effect of this is to drive off moisture and carbonic acid, and the ore is then ready for the *blast furnace* (see *HOT-BLAST FURNACE*). The interior of the furnace is lined with the very best fire-bricks, and the exterior is formed of a casing of solid masonry strengthened with iron hoops. Great care and expense are bestowed in the construction of these furnaces, and when the fire has been kindled it is never allowed to go out until the furnace needs repairs; so that such a furnace will continue in activity without intermission for a period of ten years, being regularly supplied at proper intervals with alternate charges of coal and a mixture of roasted ore with limestone in fragments. The limestone is added in order to render fusible the clay, and other earthy matter, which are associated with the carbonate of iron; these matters melt and form the glassy-looking slags that in a molten state are continually flowing over the tymstone. The air which issues from the tuyeres is soon deprived of its oxygen by the excess of carbon, producing carbonic oxide, — and this gas, ascending, penetrates the heated ore, rendered porous by the previous roasting. Carbonic oxide is a combustible gas, and at the high temperature of the furnace it takes away oxygen from the *I.*, which then combines with a small proportion of the carbon in the coal, fuses, and, together with the melted slag, drops into the crucible of the furnace, where it sinks to the lowest part; while the slag floats on its surface, and flows over the tymstone as it accumulates, at the same time covering the surface of the melted *I.*, which otherwise would be oxidized by the blast, and would, in fact, burn by again uniting with oxygen.

The *I.* — which thus prepared always contains from 2 to 5 per cent of carbon — is drawn off at intervals of 12 or 24 hours by the removing with an *I.* rod the plug of clay stopping the tap-hole. The liquefied metal is allowed to run into a series of shallow channels formed in sand, where it solidifies, and when cold is broken into suitable lengths, and then presents itself in the form of the bars commonly known as *pig-I.* This is the crude *cast-I.*; and here it will be desirable to refer to the fact that *cast-I.* is not simply *I.*, but a chemical compound of *I.* and carbon. As it runs from the smelting furnace, however, it contains many other substances, such as silicon, uncombined carbon, manganese and other metals, phosphorus, sulphur, etc. The properties of the metal are greatly modified by these bodies, even when present in very small proportions. In the variety of *cast-I.* known as *white-I.* all the carbon is chemically combined with the metal, while in the *gray* and *mottled* varieties some of the carbon is separated from the *I.*, and is merely mechanically diffused throughout the mass in the form of small crystals, similar to those of graphite or plumbago. The following table shows the percentage composition of some samples of *cast-I.* : —

	White.	White.	M't'd.	Gray.
Iron.....	88.81	89.374	93.29	90.376
Combined carbon.....	4.94	2.457	2.78	1.021
Graphite, or uncombined carbon.....	—	0.871	1.99	2.641
Silicon.....	0.75	1.124	0.71	3.061
Sulphur.....	trace	2.513	trace	1.139
Phosphorus.....	0.12	0.913	1.23	0.928
Manganese.....	5.33	2.815	trace	0.834

These examples will suffice to show that the composition of *cast-I.* varies greatly; and there are also wide differences in the mechanical properties of each variety. *Gray-I.*, that which is commonly produced from the furnace, is not so hard as the other kinds of *cast-I.*; it can be filed, or drilled, or turned in a lathe. The mottled variety is very tough, and on that account is preferred for casting guns. *White cast-I.* has, when broken across, a white lustre, and the fracture presents a lamellar crystalline texture. It is more fusible than the others, but it is very brittle, and so hard that it cannot be worked with steel tools. *I.* possesses a property which is by no means common to all the metals. — a property upon which chiefly depends its admirable suitability for receiving any required form by casting. At the moment that a mass of the fluid metal solidifies, its bulk increases, so that this metal is capable of receiving even delicate markings from the moulds in which it is cast. — No greater improvement was ever effected in any art by simple means than that introduced into *I.* smelting by the substitution of hot air for cold in the blast furnace. When a current of cold air is employed to urge on the combustion, it is evident that a portion of the heat produced is taken up in heating the nitrogen, which constitutes four fifths of the bulk of atmospheric air, and takes no part in the combustion. But when the air is heated to a high temperature before entering the furnace, no such cooling effect is

produced, and consequently a much greater intensity of heat is obtained. The quantity of air blown into a blast furnace is enormous, its weight being greater than that of all the coke, ore, and limestone put together. It is calculated that the weight of the air passing through a smelting furnace amounts, in some cases, to between 2,000 and 3,000 tons in a week. It is not the total quantity of heat produced by the consumption of fuel throughout the whole mass of the materials in the smelting furnace that is effectual in the reduction of the oxide to the metallic state, or in the smelting of the slag; and the *I.* A certain temperature must be obtained before any reduction or fusion takes place, and no amount of fuel burnt under conditions in which the requisite intensity of heat is not attained is of any avail in producing the required effect. Probably this important invention was rather a lucky hit than a result to which the inventor was led by the theory of the blast furnace as then understood; but the fact is undoubted that employment of hot-blast economizes fuel to an extent quite unexpected, and of which 50 per cent is perhaps not too high an estimate. For the production of the hot-blast, the air is made to pass through a series of pipes or chambers heated by a separate furnace, so that it may enter the smelting furnace at a temperature sufficiently high to melt a strip of lead held in a current of it, that is, about 620° F.

A mode of still further economizing fuel, introduced by Mr. Siemens, is by causing the hot gases which escape from the smelting furnace to pass through a chamber filled with fire-bricks, so arranged that the gases circulate freely round them; and when the bricks are by this means heated to redness, the current of gases is shut off from the chamber, and conducted through another precisely similar; while the blast of cold air is made to circulate through the heated chamber, and thus acquires a temperature of 1,200° or 1,300° F. Two of these chambers are used alternately, so that while one is employed in heating the blast, the other is acquiring from the furnace gases the heat necessary for it to perform the same duty. In this manner a great part of the heat of the waste gases is utilized.

Fig. 230. — CUP AND CONE.

Other modes of employing the gases escaping from the chimneys of the smelting furnaces have also been adopted. — It will be remembered that the most active agent in the reduction of the metal is the carbonic oxide gas produced in the furnace by the incomplete combustion of the carbon of the coal. A large excess of this gas is produced, and escapes from the chimney of the furnace. The unconsumed carbonic oxide gas, forming together with the hydrogen and other combustible gases, forms more than a third of the gases issuing from the furnace. It is the combustion of these inflammable gases which produces the lambent flames often seen at the mouths of smelting furnaces, and imparting its most striking features to the night view of an *I.*-smelting region. Until recently, all the heat produced by these flames was absolutely wasted, but by various expedients a portion of the whole of these gases is now drawn off and allowed to burn in such a manner that the heat is available for raising steam or for heating the air-blast. It is obvious that if the gases are withdrawn from the furnace without checking the upward current, the processes could not suffer in any way. One very effective manner of doing this is shown in Fig. 230, which is a section through the upper part of a smelting furnace, with the "cup and cone" arrangement. The mouth of the furnace is covered with a shallow *I.* cone, *a*, open at the bottom, into which fits another cone, *b*, attached to a chain, *c*, sustained by an arm of the lever, *d*, which is firmly held in the required position by the chain, *e*, and is also provided with a counterpoise, *f*. In this position the mouth of the furnace is closed, and the gases find an exit by the opening, *g*, seen behind the cones, and leading into a passage through which the gases are conveyed to the place where they are required to be burnt. The charge for the furnace is filled into the hopper, *a*, and at the proper time the chain, *c*, is slackened, when the weight of the materials resting in the sus-

pendent cone overcomes that of the counterpoise, and the charge slides down over the surface of the cone, *b*, which is immediately drawn up again by the counterpoise, so that the opening is at once closed.

*Cast-I.*, it is well known, cannot be wrought with the hammer; it cannot be rolled into plates, nor welded on an anvil; it is not readily filed or worked with steel tools; and it possesses no ductility, and little tenacity, or power to resist a pulling force. On the other hand, *wrought-I.* possesses all these properties in the highest degree, but can be fused only by an extremely intense heat. In chemical composition the latter is essentially pure *I.*, whereas the former is essentially a compound of iron and carbon. *Cast-I.* is converted into wrought-*I.* by the processes of *refining* and *puddling*. The object of these operations is, as may be imagined, the removal of the carbon and other substances. The pig-*I.* is re-melted on the hearth of a furnace in such a manner that it is exposed to the action of the air for about two hours. The silicon, most of the carbon, and some of the *I.* itself are oxidized in this process. At one stage in the process the metal appears to boil, owing to the escape of jets of carbonic acid gas, formed by the union of oxygen and carbon in the midst of the mass. The oxidizing action is carried on through the whole, for the puddler stirs it up, so that every part is brought into contact with the oxygen, or with the oxide of *I.* formed on the surface, and carried by the stirring into the heart of the mass. With this object the *I.* is sometimes mixed with oxide of *I.* from the forge. As the *I.* loses its carbon it becomes less fusible, and at length the metal becomes a mass of loosely adhering grains, like so much damp sand. The heat is now raised, and the grains begin to fuse and become more adherent, so that the puddler is able to collect all the metal at the end of an *I.* rod into a spongy mass. He forms this into balls, or *blooms*, weighing about 70 lbs. each. The blooms consist of particles of nearly pure *I.*, partly fused together, but retaining in the interstices between them a portion of the fused slags, oxides, and other extraneous matters. They are now delivered to the *shingler*, by whom they are submitted, whilst still intensely hot, to the action of a steam hammer or other heavy hammer, or subjected to compression in a *shingling* press, or passed be-

Fig. 291. — FIBROUS FRACTURE OF WROUGHT-IRON.

tween massive *I.* rollers. The design of this treatment is to compress the half-fused particles of *I.* into a compact mass, and to thoroughly squeeze out the slag and fused oxide. In any case the operation is concluded by passing the metal between grooved rollers, by which it is formed into bars. These are afterwards cut into lengths, reheated, and the rolling repeated, and so on several times, when the *I.* is required to possess great tenacity. The rolling of the blooms into bars is a striking spectacle. The furnace door is opened, the workman pulls out a white-hot ball, he throws it on the ground, whence it is instantly snatched up by an attendant Vulcan, armed with a pair of tongs, and applied to the largest-sized groove in a pair of massive rollers. The lump of *I.* is shot through the rolls and is doubled in length by their pressure. No sooner has it come out than it is again seized and tossed back over the rollers, to be again passed through a smaller groove; and it thus passes backwards and forwards several times, increasing its length and improving in quality with each passage through the grooves. The whole operation is effected in an incredibly short time, and before the spectator has been able fully to comprehend the process the result is before him,—a long, straight, finished bar of glowing *I.* is stretched on the sand; and scarcely has the bar been laid out to cool than another fiery mass is following the same course through the rolls.

*Wrought-I.* is never pure, but always contains a small proportion of carbon, varying from one fifth to one half per cent. The presence of this small quantity of carbon enhances rather

than impairs its useful qualities; but some of the other ingredients of cast-*I.*, if not entirely removed in the refining and puddling processes, act most injuriously upon the qualities of the wrought-*I.* For example, the presence of a small proportion of phosphorus renders wrought-*I.* brittle and rotten when cold, although at a red heat it may be forged. *I.* having this defect is technically said to be *cold short*, while the term *red short* is applied to metal which when hot breaks and crumbles under the hammer, a condition occasioned by the presence of a small quantity of sulphur or silicon. Wrought-*I.* is quite unlike cast-*I.* in texture, which we may compare to that of loaf-sugar; the former exhibits a fibrous grain, not unlike that of a piece of wood. This fibrous structure depends upon the mechanical treatment the *I.* has received, and in bars the fibres always arrange themselves parallel to the length of the bar. Fig. 291 shows the fibrous structure in a piece of *I.* when a portion has been wrenched off. Like wood, wrought-*I.* has much greater tenacity along the fibres than across them; that is, a much less force is required to tear the fibres asunder than to break them across. Consequently, to obtain the greatest advantage from the strength of wrought-*I.*, the metal must be so applied that the chief force may act upon it in the direction of the fibres.

*Steel* is a nearly pure compound of *I.* with carbon, the proportion of the latter element being much less than in cast-*I.*, and always less than one fiftieth. Good steel contains from 0.7 to 1.7 per cent of carbon, and some excellent qualities have been found to have from 1.3 to 1.5 per cent of carbon, together with 0.1 per cent of silicon. Steel is thus, as regards carbon, intermediate in composition between wrought and cast *I.*, and in a great measure possesses the most valuable properties of both. It may be wrought on the anvil at a white heat, and at a higher temperature it may be melted and cast in a mould. It is distinguished from cast-*I.* by its fine, close grain, and still more by its remarkable tenacity, in which property it excels wrought-*I.*; for, while a bar of the best wrought-*I.*, 1 in. sq., breaks with a load of thirty tons, a bar of good steel of the same size will sustain 75 tons, and, if the steel has been subjected to certain processes, its tenacity may even reach 120 tons. Still more remarkable is the wonderful property possessed by steel by which it may at will be made soft or hard, tough or elastic. If suddenly quenched in water when it is red hot, it acquires a hardness rivalling that of the diamond, and is also rendered very brittle and extremely elastic. The hardness and brittleness can be reduced by *tempering* to any required extent. Steel may be made either by stopping the processes by which carbon is removed from cast-iron at such a stage as to leave the requisite quantity of carbon in combination with the *I.*, or by reversing the decarbonizing process and recombining wrought-*I.* with carbon. In the latter plan, bars of the finest wrought-*I.* are heated for a week in a closed receptacle, tightly packed with powdered charcoal. But all the older plans for producing steel by the partial decarbonization of cast-*I.* have been eclipsed in interest and importance by Bessemer's discovery that the carbon and silicon may be readily removed by forcing currents of cold air through a mass of the fused metal. (See STEEL.)

*Spiegeleisen* (literally *mirror-I.*), a white hard cast-*I.*, has had that name given to it by the Germans, from the fact that when it is broken across the fractured surfaces present numerous little mirror-like faces of crystals, having a pure silvery lustre. This *I.* is procured from ores which contain manganese, and it also retains a very large proportion of carbon. The composition of an average specimen of spiegeleisen may be stated as showing 4 to 4½ per cent of carbon, 10 per cent of manganese, and 1 per cent of silicon.

#### PRODUCTION OF IRON AND STEEL IN THE U. STATES.

The following table shows, in tons of 2,000 lbs., the production of all kinds of *I.* and steel in the U. States for the years 1876, 1877, and 1878:—

PRODUCTS.	1876.	1877.	1878.
Pig-iron .....	2,093,286	2,314,585	2,577,861
All rolled iron, including nails and iron rails.....	1,509,269	1,476,759	1,555,576
All rolled iron, including nails and excluding rails	1,042,101	1,144,219	1,232,686
Bessemer steel rails.....	412,461	432,169	550,898
Open-hearth steel rails.....	.....	.....	9,887
Iron and all other rails.....	467,168	832,540	322,890
Rails of all kinds .....	879,629	764,709	882,685
Kegs of cut nails and spikes, included in all rolled iron	4,157,814	4,828,918	4,386,130
Crucible cast-steel.....	39,382	40,430	42,106
Open-hearth steel.....	21,490	25,081	36,126
All other steel, except Bessemer.....	10,306	11,924	8,556
Bessemer steel ingots.....	525,936	560,587	732,226
Blooms from ore and pig-iron .....	44,628	47,300	50,045
Spiegeleisen, included in pig-iron .....	6,616	8,845	10,674

*Fig. 1.* The high price of *I.*, which prevailed during the rapid extension of our railroad network, made it profitable to work furnaces and forges whose locations and facilities would be very disadvantageous in times of ordinary demand. Since the demand for railroad *I.* considerably declined, the prices, owing to the excessive increase in the exceedingly expensive works necessary for *I.* production, and to the large accumulation of stocks to be disposed of, declined in a far greater ratio; so that no branch of industry has been in a worse financial position for some years past than the *I.* trade. The lowest production since the panic of 1873 was in 1876. The production has since steadily increased, but the prices obtained for pig-*I.* have not kept pace with the increase in production. The highest average monthly price at which best anthracite pig-*I.* has ever been sold in Philadelphia was in August, 1861, when \$73.624 were paid; the lowest average monthly price at which sales of the same quality of pig-*I.* have been made was in November, 1878, when \$16.50 were accepted. Since that month prices have slightly advanced, till the beginning of 1880, when the scarcity of ore, keeping many furnaces out of blast, made prices bound upwards again, with such feverish fluctuations as to cause much uneasiness among *I.*-makers, their fear being that values were going to reach a point from which they would drop with a thud before long. It is, however, an established fact that the consumption of pig-*I.* in this country has greatly increased since 1876; and that this increase, if it is partly owing to rapid development of the Bessemer branch of our steel industry, is also partly due to an improvement in the business of the foundries and machine-shops of the country.

The number of furnaces in blast at the close of 1878 was 265; out of blast, 427. At the close of 1877 the number in blast was 270; out of blast, 446. As the production of pig-*I.* was 262,776 net tons greater in 1878 than in 1877, it is clear, from a comparison of the number of furnaces in blast in each of these years, that our furnace practice greatly improved in 1878. In this connection it is interesting to note the improvement in the management of our furnaces which has taken place since 1873. At the close of that year there were 410 furnaces in blast, and the production of the year was 2,868,278 net tons, or an average of 6,996 tons for each furnace; at the close of 1878 there were 265 furnaces in blast, and the production of the year was 2,577,361 tons, or an average of 9,726 tons for each furnace. These averages are, of course, only approximations to the actual results, the number of furnaces in blast in any one year varying with the months and possibly with the days of the year; but the basis of calculation is the same in each of the two years taken, and the averages obtained are therefore in a comparative sense correct. They indicate that the average production of the furnaces in blast in 1878 was almost

40 per cent greater than that of the furnaces in blast in 1873. The superior results obtained in 1878 were due in part to the use of a larger proportion of large furnaces; in part to greater skill in all the details of furnace management; and in part to the increased use of better ores and of Connellsville coke.

The following table shows in tons of 2,000 lbs. the production of pig *I.* in the U. States from 1854 to 1878, classified according to the fuel used:—

Years.	Anthracite.	Charcoal.	Bituminous	Total.
1854	339,435	342,298	54,485	736,218
1855	381,899	339,922	62,360	784,178
1856	443,113	370,470	69,554	883,137
1857	390,385	330,321	77,451	798,157

Included in the aggregate pig *I.* production of the country in the past few years is the small quantity of spiegel-eisen which has been produced. The number of net tons of spiegel-eisen produced in 1878 was 10,674, against 8,845 tons in 1877, 6,616 tons in 1876, and 7,832 tons in 1875.

*Iron and Steel Rails.* The following table shows the production in net tons of rails of all kinds in the U. States from 1871 to 1878, classified by States, together with the percentage made in each State in 1878:—

States in the order of their rail production in 1878.	1871.	1872.	1873.	1874.	1875.	1876.	1877.	1878.	Percentage made in 1878.

The production of *I.* and steel rails in this country, from the beginning of the manufacture of Bessemer steel rails down to 1878, was as follows:—

Years.	Iron Rails, all kinds, Net tons.	Bessemer Steel Rails, Net tons.	Total, Net tons.
1867	459,558	2,550	462,108
1868	499,489	7,225	506,714
1869	583,936	9,650	593,586
1870	586,000	34,000	620,000
1871	737,483	38,250	775,733
1872	905,930	94,070	1,000,000
1873	761,062	129,015	890,077
1874	584,469	144,944	729,413
1875	501,649	290,893	792,512
1876	467,168	412,461	879,629
1877	332,540	492,169	764,709
1878	332,387	550,398	882,685

The highest price ever obtained in this country for *I.* rails was in 1864, when it rose in September to \$153.75, the average for the year being \$126. In succeeding years the price steadily declined to \$32.50, reaching its lowest price in October, 1877; since which time prices have gradually advanced. The first importation of Bessemer steel rails into the U. States was in 1863, when a few tons were imported from England, and \$150 a ton was paid for them in gold. In 1867, when this country first began to make them to fill orders, the price of English steel rails fell in our markets to \$118 in gold. As a result of the domestic competition in the manufacture of steel rails which was established in that year, the price of these rails has since declined with great regularity, until in 1877 American Bessemer rails were sold as low as \$40 a ton, with an average for the year of \$45.50; while in 1878 the average fell to \$42.25. As both our imports and exports of rails of all kinds in 1878 were only nominal, it may be fairly assumed that the domestic consumption of rails in that year was equal to the production. The following table will show approximately the consumption of rails in this country from 1867 to 1878:—

Calendar Years.	Made in U. States. Net tons.	Imported Net tons.	Probable Consumption. Net tons.
1867.....	462,108	163,049	625,157
1868.....	506,714	250,081	756,795
1869.....	593,586	313,163	906,749
1870.....	620,000	399,153	1,019,153
1871.....	775,733	{ Iron, 515,000 } { Steel, 50,701 }	1,341,434
1872.....	1,000,000	{ Iron, 381,064 } { Steel, 149,786 }	1,530,850
1873.....	890,077	{ Iron, 99,201 } { Steel, 159,571 }	1,148,849
1874.....	729,413	{ Iron, 7,796 } { Steel, 100,515 }	837,724
1875.....	792,512	{ Iron, 1,942 } { Steel, 16,316 }	810,770
1876.....	879,629	{ Iron, 287 } { Steel, None }	879,916
1877.....	764,709	{ Iron, None } { Steel, 35 }	764,744
1878.....	882,685	{ Iron, None } { Steel, 10 }	882,695

*Roller Iron.* The production of all kinds of rolled *I.* in the U. States in 1878, including *I.* rails, was 1,555,576 net tons, which was an increase of 78,817 tons over the production of 1877. Appended is a table which shows the production of *I.* rails and of all other forms of rolled iron since 1864. By the term rolled *I.* we include (1) *cut nails and spikes*; (2) *bar, angle, bolt, rod, skelp, and hoop I.*; (3) *plate and sheet I.*; and (4) all sizes of *I. rails.* Bessemer steel rails are not classed among rolled *I.* products.

Years.	Iron Rails. Net Tons.	Other rolled <i>I.</i> Net tons.	Total. Net tons.
1864.....	335,339	533,958	872,327
1865.....	353,292	500,048	856,340
1866.....	430,778	595,311	1,026,089
1867.....	459,558	579,838	1,039,396
1868.....	499,489	598,286	1,097,775
1869.....	583,933	642,420	1,226,356
1870.....	586,000	705,000	1,291,000
1871.....	737,483	710,000	1,447,483
1872.....	905,930	941,922	1,847,922
1873.....	761,062	1,076,393	1,837,455
1874.....	584,469	1,110,147	1,694,616
1875.....	501,649	1,097,837	1,599,516
1876.....	467,168	1,042,101	1,509,269
1877.....	332,540	1,144,219	1,476,759
1878.....	322,890	1,232,686	1,555,576

This table shows that the production of *I.* rails reached its maximum in 1872, and that it has annually declined since that year, the decline in 1878, as compared with 1877, being, however, only 9,650 tons. It further shows that the production of all other forms of rolled *I.* reached its maximum in 1878, when 88,467 more tons were produced than in 1877, and 156,318 more tons than in 1873, the year of the panic. The production of all rolled *I.*, exclusive of rails, more than doubled from 1868 to 1878.—The production of *bar, angle, bolt, rod, skelp, and hoop I.* in 1878 was 830,837 net tons, against 720,531 tons in 1877, 668,956 tons in 1876, 668,755 tons in 1875, 687,650 tons in 1874, and 705,964 tons in 1873. The production of *plate and sheet I.* in 1878, not including nail plate, was 182,042 net tons, against 182,242 tons in 1877, 165,255 tons in 1876, 192,769 tons in 1875, 176,888 tons in 1874, and 169,169 tons in 1873. The production of *cut nails and spikes* in 1878 was 4,396,130 kegs of 100 pounds each, against 4,828,918 kegs in 1877, 4,157,814 kegs in 1876, 4,726,881 kegs in 1875, 4,912,180 kegs in 1874, and 4,024,704 kegs in 1873. The tonnage of rolled *I.* converted into cut nails and spikes in 1878 and previous years was as follows: 1878, 219,807 net tons; 1877, 241,446 tons; 1876, 207,890 tons; 1875, 236,343 tons; 1874, 245,609 tons; 1873, 201,235 tons.

*Steel of all kinds.* The quantity of pig-*I.* spiegelisen, and ferro-manganese converted into steel by the Bessemer process in the U. States in 1878 was 739,765 net tons, against 562,227 tons in 1877. Of spiegelisen and ferro-manganese alone there were used 61,466 tons, against 43,229 tons in 1877, 45,980 tons in 1876, and 33,245 tons in 1875. The number of net tons of Bessemer steel ingots produced in 1878 was 732,226, against 560,587 tons in 1877. The number of net tons of Bessemer steel rails produced in 1878 was 550,398, against 432,169 tons in 1877. In addition to the rails produced, there were sold or worked up by the Bessemer works into other forms 73,370 net tons of ingots. There were ten Bessemer steel works in operation in 1878, the only remaining works, the Vulcan, at St. Louis, being idle. The works which were in operation used only 20

converters. Down to the close of 1878 this country had produced a total of 2,145,595 net tons of Bessemer steel rails. The following table shows in net tons the production of all kinds of steel in the U. States from 1872 to 1878:—

Kinds of Steel.	1872.	1873.	1874.	1875.	1876.	1877.	1878.
Bessemer steel ingots	120,108	170,632	101,333	35,517	325,096	590,587	732,226
Crucible cast steel	21,399	34,795	35,328	30,401	30,382	40,430	42,906
Open-hearth steel	3,000	3,500	7,000	9,950	21,400	23,631	36,123
All other steel	7,740	13,714	6,353	12,697	10,306	11,224	8,536
Total	160,166	222,632	241,614	496,575	507,174	657,972	819,814

It is one of the most interesting facts connected with the industrial development of our country, that the domestic Bessemer steel manufacture should have moved forward with giant strides during a period of such wide-spread and paralyzing depression as has prevailed in the U. States and in most other countries from 1873 to 1878. No example could better illustrate the abounding faith, the resolute courage, and the business sagacity of the American people, or more pointedly illustrate the real wealth of the country, both in material resources and pecuniary accumulations. Of the ten Bessemer steel establishments which made steel in 1878, one is in New York, five are in Pennsylvania, one is in Ohio, and three are in Illinois.

*Blooms and Billets* from ore are made mainly in the Champlain district of New York; blooms from pig and scrap *I.* are made mainly in Pennsylvania. The make of each product in the three years, 1873, 1877, and 1878, in net tons was as follows:—

Kind of Product.	1873.	1877.	1878.
Blooms and billets from ore.....	32,863	24,227	24,139
Blooms from pig and scrap iron...	29,701	23,073	25,906
Total.....	62,564	47,300	50,045

*Iron ore imported.* The value of the *I.* ore imported into the U. States in the nine years from 1870 to 1878 is given in the following table. The number of tons imported in any one year may be approximately ascertained by dividing the value of the imports for that year by two, the invoice value of all the ore that has been imported being about two dollars a ton.

Fiscal Year.	New York.	Lake Ports.	Philadel-phia.	Other Ports.	Total.
1870.....	\$	\$ 34,439	\$	\$ 165	\$ 34,604
1871.....	153	66	.....	143	262

**Import duty:** old scrap (cast, \$6 per ton, wrought, \$8 per ton). Molise I, made of sand ore by one process, \$15 per ton. Bars, rolled or hammered, including flats not less than 1 in. nor more than 6 in. wide, nor less than 3 in. nor more than 2 in. thick, and rounds not less than 3 in. nor more than 2 in. in diameter, and squares not less than 3 in. nor more than 2 in. square, 1 cent per lb. Bars, including flats less than 3 in. and not above 2 in. thick, nor less than 1 in. or more than 6 in. wide, rounds less than 3 in. nor more than 2 in. in diameter, and squares less than 3 in. or more than 2 in. square, 1 1/2 cents per lb. Other descriptions of rolled or hammered I, n. o. p., 1 1/2 cents per lb. Bars, for railroads or inclined planes, made to pattern and fitted to be laid down, not above 6 in. high, 70 cents per 100 lbs. Band, hoop, slit, and rolled or hammered, and scroll, from 1/4 in. to 6 in. wide, not below 1/4 in. thick, 1 1/2 cents per lb.; from 1/4 in. to 6 in. wide, less than 1/4 in. thick, not less than No. 20 wire-gauge, 1 1/2 cents per lb.; thinner than No. 20 wire-gauge, 1 1/2 cents per lb. Boiler and other plate, n. o. p., \$25 per ton; not less than 3/4 in. thick, 1 1/2 cents per lb. Rods, nail or spike, slit, rolled, or hammered, 1 1/2 cents per lb. Sheet I, smooth or polished, all, 8 cents per lb.; galvanized or coated with zinc, 2 cents per lb.; other sheet I, common or black, not thinner than No. 20 wire-gauge, 1 1/2 cents per lb.; thinner than No. 20, not thinner than No. 25, 1 1/2 cents per lb.; thinner than No. 25, 1 1/2 cents per lb. Squares, marked on one side, 3 cents per lb., and 30 per cent; all other, of iron or steel, 6 cents per lb., and 30 per cent. Anchors, and parts thereof, 2 1/2 cents per lb. Andirons, cast, 1 1/2 cents per lb. Anvils, 2 1/2 cents per lb. Axes, or parts thereof, 2 1/2 cents per lb. Blacksmiths' hammers or sledges, 2 1/2 cents per lb. Bolts, wrought, 2 1/2 cents per lb. Butts, cast, 2 1/2 cents per lb. Castings, n. o. p., 30 per cent. Cables or chains, or parts thereof, 2 1/2 cents per lb. Chains, trace, halter, or fence, of wire or rods, 1/4 in. in diameter or more, 2 1/2 cents per lb.; under 1/4 in. in diameter, not less than 1/4 in. in diameter, 2 1/2 cents per lb.; under 1/4 in. in diameter, not under No. 9 wire-gauge, 3 cents per lb.; under No. 9 wire-gauge, 35 per cent. Hatters' irons, 1 1/2 cents per lb. Hinges, cast, 2 1/2 cents per lb.; wrought, 2 1/2 cents per lb. Hollow-ware, glazed, tinned, 3 1/2 cents per lb. Malleable, in castings, 2 1/2 cents per lb. Mill-irons and cranks, 2 cents per lb. Nails and spikes, cut, 1 1/2 cents per lb. Board nails, wrought (spikes and rivets), 2 1/2 cents per lb. Nails, horseshoe, 5 cents per lb. Nuts and washers, wrought, ready punched, 2 cents per lb. Pipe, cast, for steam, gas, or water, 1 1/2 cents per lb. Railroad-chairs, wrought, 2 cents per lb. Sad-irons, 1 1/2 cents per lb. Screws, bed, 2 1/2 cents per lb.; wood screws, over 2 in. in length, 8 cents per lb.; under 2 in. in length, 10

cents per lb.; washed or plated, and all other, 35 per cent. Stoves, and stove-plates, of cast iron, 1 1/2 cents per lb. Tailors' irons, 1 1/2 cents per lb. Tacks, sprigs, trade cut, not exceeding 16 ounces per mille, 2 1/2 cents per lb. Taggers' iron, 30 per cent. Tire for locomotives, 3 cents per lb. Tubes, flues, etc., for steam, gas, and water, wrought, 3 1/2 cents per lb. Vessels, cast iron, n. o. p., 1 1/2 cents per lb. Wire, bright, coppered, or tinned, drawn and finished, not above 1/4 in. in diameter, nor thinner than No. 16 wire-gauge, 2 cents per lb., and 15 per cent; thinner than No. 16, not thinner than No. 25, 3 1/2 cents per lb., and 15 per cent, beyond No. 25, 4 cents per lb., and 15 per cent; covered, cotton, silk, etc. (additional), 5 cents per lb. Provided, That all wire-rope and wire-strand, or chain made of iron wire, either bright, coppered, galvanized, or coated with other metals, shall pay the same rate of duty that is now levied on the iron-wire of which said rope, or strand, or chain, is made; and all wire-rope and wire-strand or chain, made of steel-wire, either bright, coppered, galvanized, or coated with other metals, shall pay the same rate of duty that is now levied on the steel-wire of which said rope, or strand, or chain is made. Wrought-I. for ships, locomotives, or parts thereof, weighing 25 pounds or more, 2 cents per lb. All manufactures of I, n. o. p., 35 per cent. Liquor, 10 per cent. Sulphate of I, 1/2 cent per lb.

**Iron-clad Vessel.** So long as the guns employed in naval warfare were limited to 68-pounders as a maximum, strongly built timber ships were considered sufficient for the necessities of the case; but when ordnance hurling shot and shell of 100 lbs., 200 lbs., or even 300 lbs. weight came into use, the bulwarks were no longer adequate. Hence the invention of iron-clads, or armor-plated ships. The first actually built were some floating batteries used by the French during the Crimean War in 1854; they were not only built of iron, but were coated with thick iron slabs. The English government, following the example, built eight floating batteries in 1856,—very slow and unmanageable ships. The civil war of 1861 gave great impetus to improvements in iron-clad vessels, and numerous modifications of plan have been adopted, to ascertain which among them possesses a preponderance of practical advantages. Large timber-built men-of-war, whether finished or not, have been cut down in height, increased in length, and clad with 4 1/2-inch armor plates, backed by 30 inches of solid timber. Some of the timber ships, thus altered, lengthened, and armed, have been provided with solid projecting rams of great weight and power, to pierce an enemy's side. Some, to render the ship more buoyant, have had the armor plates only over the most exposed parts; while others have been clad from stem to stern. Some have had the guns placed in a revolving turret of immense strength, instead of as a broadside in the usual way. (See MONITORS and TURRET SHIPS.) A plan has been tried in a few cases of notching or bevelling the sides of the ship in such a way that the guns may be trained to take a very wide sweep, so as to fire, if needed, much nearer in a line with

the keel than is usually practicable. After many partially built timber ships were converted into iron-clads, others built wholly of iron were commenced; and these form the most formidable class of the two. To ascertain the effect of actual size, the English Admiralty have built the vast ships *Northumberland*, *Agincourt*, and *Minotaur*, each about 400 feet long and 7,000 tons burden, with 5½-inch armor plates. To ascertain the capabilities of the armor without immediate reference to the size of the ship, plates have been used 6, 7, 8, and even 9 inches in thickness. Various modes of arranging the armament have been adopted, as a means of determining whether it will be better to have a moderate number of guns throwing 100-lb. to 200-lb. shot and shell, or a few of those monster guns which will hurl from 300 lbs. to 600 lbs. of metal against the enemy. A terrible naval war will alone settle these and many other disputed questions.

**Iron-Foundry**, a place where iron castings are made.

**Iron-Heater**, the piece of metal which is heated in the fire for a laundress's box-iron or Italian iron.

**Iron-Holder**, a stand for a laundress's smoothing-iron.

**Ironing-Blanket**, a coarse blanket used as a smooth surface by laundresses when ironing linen.

**Ironing-Board**, a tailor's board on which cloth is pressed with an iron to smooth the seams, etc.; a laundress's board, covered with flannel, for ironing ladies' dresses; a table.

**Ironing-Machine**, a machine of which there are several forms, adapted for ironing clothes, hat-ironing, hosiery, for tailors, etc.

**Iron-Liquor**, a solution of acetate of iron used as a mordant by calico printers. It is usually called printers' liquor.

**Iron-Master**, a manufacturer of raw and bar iron; the owner of smelting works, or blast furnaces, for making iron from the ore.

**Iron-Merchant**, a wholesale dealer in iron.

**Ironmongery**, the English term for hardware.

**Iron-Mould**, a mark on linen made by the rust of iron.

**Iron-Paper**. See SHEET-IRON.

**Irons**, tools for heating at a fire, as laundresses' flat and box smoothing-irons for clothes; tailors' and hatters' irons, etc. — The poker, tongs, and shovel, for a grate. — Shackles or manacles for the legs.

**Iron-Scraps**, the cuttings and parings of iron-work which are saved, collected together, and melted again in the puddling furnace.

**Ironsmith**, a worker in iron.

**Iron Spoon**, a kitchen spoon used by cooks.

**Iron-Stone**, the argillaceous carbonate of iron, commonly known as clay iron-stone. See PORCE-LAIN.

**Iron Vessel**. See SHIP-BUILDING.

**Iron Wire**. See WIRE.

**Iron-Wood** [Fr. *bois de fer*; Ger. *Eisenholz*; It. *legno di ferro*; Sp. *plo hierro*], a common name for many trees, producing hard, ponderous, close-grained woods; in America, for the *Ostrya Virginica*, a tree which only grows to a small size, but the white wood is compact, finely grained, and heavy. There is an iron-wood in Brazil, but the tree yielding it is not defined. Another iron-wood entering into commerce is the *Metrosideros verus*, brought from China. The *Argania sideroxylon*, of Morocco, is another close, hard wood which sinks in water.

**Iron-Work**, anything made of iron; the parts

or pieces of a building or machine which consists of iron.

**Irrigation**, the practice of flooding land in arid countries.

**Irving Insurance Co.**, a fire-insurance Co., located in New York city, organized in 1872. *Statement*, Jan. 1, 1879: Cap. stock paid up in cash, \$200,000; net surplus, \$32,117.92; risks in force, \$7,112,418; premiums, \$66,507.21; premiums received since the organization of the Co., \$646,008.84; losses paid, \$372,308.79; cash dividends paid to stockholders, \$120,000.

**Isinglass, Fish-Glue** [Fr. *colle de poisson*; Ger. *Hausenblase*; It. *cola di pesce*; Russ. *klei rybii, karluk*], one of the purest and finest of the animal glues, is a variety of gelatine, prepared from the air-bag, swimming-bladder, or sound of various fishes. The Russian and Siberian *I.* is most esteemed; it is chiefly obtained from sturgeons. The swimming-bladder is cut up, washed, and then exposed to the air, with the inner silvery membrane upward. When dry, this membrane is removed by beating and rubbing; the sound is then prepared in various ways. For forming what is called *leaf I.*, it is merely dried; for *long* and *short staple*, it is twisted between three pegs, into the shape of a horseshoe, harp, or lyre; for *book isinglass*, it is folded like the sheets of a book; for *ribbon I.*, it is rolled out. The swimming-bladder of *Acipenser sturio* of the Caspian Sea furnishes leaf isinglass of three qualities, known as *fine-firsts*, *firsts*, and *seconds*. A sturgeon of the Caspian and Black Seas and their tributary rivers yields staple and leaf *I.* The varieties of staple are *Patriarch Astrakhan*, and *Astrakhan firsts, seconds, and thirds*. The varieties of leaf are also *firsts, seconds, and thirds*, — the firsts forming the finest leaf known in commerce. There is also the *sisane leaf*, said to be obtained from a small fish, and *kroski I.*, which is made into small membranous disks. *I.* is also procured from *Siluris glanis*. For *purse, pipe*, and *lump I.* the swimming-bladder is dried unopened, and the variety known as *Siberian purse*, of moderately good quality, is greatly in demand. Brazilian *I.* is obtained from Para and Maranham, but the fishes which produce it have not been named. For the variety known as *pipe-Brazil*, the swimming-bladders are dried unopened, and made into pipes 10 or 12 inches long, and from 2 to 2½ inches broad, and are sometimes distended with air. *Lump I.* is formed by placing two swimming-bladders side by side, and for *honeycomb I.* the largest lump *I.* is split open. The New York and New England *I.* is obtained from the sounds of the codfish and of the common hake. The *patent gelatine* prepared from glue pieces or cuttings of hides, etc., after the manner of glue, is also used as a substitute for *I.* A solid gelatine in thin plates and strings is prepared from bones, and is chiefly of French manufacture. Japanese *I.* is a substance prepared from sea-weeds.

*I.* is prepared for sale by being picked and cut. This was formerly done by hand, but is now effected by steam machinery; the thin filaments thus produced should be whitish in color, dry, semi-transparent, nearly tasteless, and quite devoid of smell. Isinglass differs from glue in being tough, fibrous, and elastic, instead of brittle. On boiling, it should completely dissolve, and on cooling, should form a white jelly, soluble in weak acids, but separable from them by alkalies. With milk and sugar it is used as a diet for invalids, and it is also used in the preparation of blanc-mange, jellies, and creams, and for enriching soups and sauces. *I.* is no longer considered to be highly nutritive; it is even less digestible than the flesh or muscular part of animals. The great consumer of *I.* is the brewer, who uses it as a fining material, for which purpose lump *I.* is chiefly used. This is deeper in color, and inferior in solubility, to the better varieties. On mixing it with the liquor to be fined, it partly combines with some of those mat-

ters which render the liquor cloudy, and entangles in its meshes those which are mechanically suspended; the whole then rising to the surface can be removed, and the liquor be left clear. Wine, coffee, and other liquids are also clarified by *I.*, but sole-skims or harshhorn shavings are often used as substitutes for it. *I.* forms the adhesive material in court-plaster, for which purpose a solution of *I.* mixed with tincture of benzoin, is brushed over black sarsenet. *I.* dissolved in spirits of wine or common gin, and gently simmered by placing the bottle in a vessel of boiling water for about an hour, forms *diamond cement*, or *white fish-glue*: gum ammoniac is sometimes added. Panes of *I.*, instead of glue, have been used instead of horn, for lanterns, and also for lamp-shades, etc.; also for window lights of vessels, being covered with a transparent varnish which is not affected by moist air. Hence, sheets of mica prepared for similar uses, as in the doors of stoves, are often called *I.*

The value of imports of *I.* into the U. States for the year 1870 was \$38,300. Imp. free.

**Ispruk**, a coarse powder made from a species of delphinium growing in Afghanistan, used in dyeing.

**Istle Grass.** See TAMPOCO FINRE.

**Italian Cloth, Farmer's Satin, Satin de Chesne**, a light material of cotton and worsted, used for coat-linings.

**Italian Iron**, a laundress's heater for fluting and smoothing frills, etc.

**Italian Juice**, the extract of licorice prepared in Calabria; that sold under the name of solazzi juice is, when genuine, most esteemed.

**Italian Wines.** Some of the best wines in Calabria are found in the vicinity of Naples. The soil there being volcanic is eminently adapted for the vine. In Calabria, though some places are too warm for vineyards, others are exceedingly well adapted to every species of vine. The principal Neapolitan wine is the *Lacryma Christi*, a sweet or rather luscious wine, which holds a place in the foremost rank of the first class produced by any country. Very little of the genuine wine is made even in the most favorable years. It is an exceedingly rich variety, of a red color and exquisite flavor. *Vino Greco* is a sweet wine from a grape of that name. A white muscadine wine, of fine color, delicate, and rich in perfume, is also made near Vesuvius. The grape of the *Vino Greco* is said to have been brought from Greece. A good deal of *Lacryma Christi*, of an inferior quality, grown in various places around Vesuvius, as at Torre del Greco and Novella, is exported as the genuine wine. The best is grown at Galitta. At Baia and Tarento both muscadine and dry wines are made of good quality. The *Lacryma Christi* of Naples is said by some to be the *Fulvian Wine* of Horace, as if anything like precision could be attained from the poet's description of the luxury in his existing works. The wines in the Roman provinces are generally common, but several of them are good. The better kinds, most probably from negligence in the manufacture, will not keep; though in the country they are thought excellent. The most delicate wine is produced at San Maimo, called *Muscatta*. Imola, near Bologna, is remarkable for its boiled wines. These in their natural state are effervescent, like Champagne. On the shores of the Lake of Garda they make a sweet wine of prime quality, called *Vino Santo*. It is not extracted from the grapes until Christmas, and is drunk at the following midsummer. Tuscany is considered the country of the vine in Italy, and it is treated there much better than in other parts of the country. The celebrated *Verdea* is a white wine, having a bright green tinge, grown at Arcetri; it was formerly held in high esteem. The red wine of Chianti, the wines of Val di Marina, Carmignano, Poncino, Antella, Artimino, and others of the same class, are produced not far

from Florence, and are several of them excellent. The wines of Sienna, among them Montalcino, Rimanze, and Santo Stefano, are good, luscious wines. The *Aleatico* of Tuscany resembles "tinto," and is a red muscadine wine, made near or at Monte Pulciano. It is a wine of great excellence, with a rich perfume. The *Malvagia* wine of Trebbio is a very fine variety. The red Florence wine, as it is called, is deeper in color than claret, and harsher, being left long on the mark. Piedmont produces red wines of tolerable quality. An effervescing wine is made at Lasseraz from the malvasia grape. Asti, near Marengo, and Biella produce red wines of good flavor. Sicily produces wine in great abundance. The best wines of the province of Mascoli grow on Etna, and are red, being almost the only good red wine of the class in the island, though others are produced at Taormina and Faro, but they have a taint of pitch. Syracuse produces over its mouldering remains a red muscadine, equal to any other in the world, if not superior. Messina furnishes much wine for exportation. The *Val di Mazara*, and the *Marsala*, when obtained without the admixture of execrable Sicilian brandy, are an agreeable wine, something like Madeira of the second class, and of great body. Augusta produces wine having a strong flavor of violets. — Wine in *I.* was formerly made almost exclusively for home consumption, and, notwithstanding the excellence of the grape and the congeniality of the climate, the general neglect of a careful and just system of culture prevented the capabilities of the Italian vineyards from being known. Of late, however, the attention of agriculturists has been turned to the cultivation of the grape, and large quantities of wine are now exported from every part of the kingdom.

**Italic**, a kind of inclined type used by printers; that in which the scientific and foreign names are given in this work.

**Italy**, a Kingdom in the South of Europe, consisting of a peninsula and the large islands of Sicily, and Sardinia. It is situated between lat. 36° 40' and 46° 40' N., and lon. 6° 30' and 18° 30' E. Previous to 1859 Italy was divided into the kingdoms of Sardinia and the Two Sicilies (Naples and Sicily), the Pontifical States, the Lombardo-Venetian province of the Austrian Empire, the Grand Duchy of Tuscany, and the Duchies of Parma and Modena. In 1859 Victor Emmanuel, king of Sardinia, obtained Lombardy, Parma, Modena, and part of the Pontifical States; Tuscany was annexed 22d March, and the Marches, Umbria, and the Two Sicilies 17th Dec., 1860, and in 1861 these were all united under the title of Kingdom of Italy, with the seat of government at Florence. By the treaty of Prague, 23d August, 1866, Venetia was added, and finally the remainder of the Papal States were annexed by royal decree 9th October, 1870, and Rome again became the capital of a united Italy. The government is a constitutional hereditary monarchy. The executive power of the State belongs exclusively to the sovereign, and is exercised by him through responsible ministers; while the legislative authority rests conjointly in the King and Congress, the latter consisting of two Chambers,—an upper one, the Senate, and a lower one, called the Camera de' Deputati. The Senate is composed of the princes of the royal house who are of age, and of an unlimited number of members, above 40 years old, who are nominated by the king for life. The number of senators in the session of 1878, was 270. The deputies of the lower house are elected

by a majority of all citizens who are 25 years of age, and pay taxes to the amount of 40 lire, or \$8. For this purpose the whole of the population is divided into electoral colleges, or districts. Neither senators nor deputies receive any salary or other indemnity. The Camera de' Deputati, in the session of 1878, numbered 508 members, being the prescribed rate of one deputy to 40,000 souls. Each of the Chambers has the right of introducing new bills; but all money bills must originate in the House of Deputies. For administrative purposes, the kingdom is divided into 69 provinces, which are again subdivided into districts and communes. In each province the executive power of the government is intrusted to a prefect appointed by the ministry. The following table gives the area and population of the larger territorial divisions, called *compartimenti*, which, for the most part, correspond to the old divisions of *I.* :—

Territorial Divisions.	Square miles.	Inhabitants (Census 1871).		Inhabitants in 1877 (official return).
		Male.	Female.	
Piedmont .....	11,306	1,450,357	1,449,207	3,027,566
Liguria .....	2,056	419,919	423,893	874,616
Lombardy .....	9,085	1,755,545	1,705,279	3,589,527
Venetia .....	9,060	1,334,364	1,308,443	2,769,594
Emilia .....	7,921	1,073,686	1,035,142	2,174,579
Umbria .....	3,720	282,574	267,027	567,131
The Marches .....	3,746	449,548	465,871	936,135
Tuscany .....	9,287	1,096,552	1,045,873	2,192,292
Rome .....	4,601	449,346	387,358	841,140

Sardinia .....	3,399	327,073	309,587	658,479
Total .....	114,415	13,472,262	13,328,892	27,769,475

The great mass of the people of *I.* are devoted to agricultural pursuits, and the town population is comparatively small. The number of inhabitants of the principal towns was as follows in 1877:—

Towns.	Population.	Towns.	Population.
Naples .....	461,627	Genoa .....	130,269
Milan .....	275,516	Venice .....	128,901
Rome .....	236,733	Bologna .....	115,957
Palermo .....	219,938	Messina .....	111,854
Turin .....	240,868	Leghorn .....	97,096
Florence .....	167,093	Catania .....	84,397

The number of emigrants from *I.*, very small previous to the establishment of the kingdom, has much increased in recent years, reaching 117,612 in 1878. The emigration is partly European, directed to France, Austria, and Switzerland, and also to South American states. In 1879 the emigration to the U. States began to assume important proportions.

**Surface and Climate.** The face of the country is much diversified by mountains. The Alps form its N. and N. W. boundary, and the Apennines, running through its whole length, determine its configuration and its physical character. The coast line of *I.* proper (see *SARDINIA* and *SICILY*) is upward of 2,000 m. From Genoa to the frontier of France the coast, called Riviera di Ponente (shore of the setting sun) is lofty and precipitous. From Genoa to Spezia is the Riviera di Levante (shore of the rising sun), which is also bold and mountainous, but less precipitous. The coasts of Tuscany and Rome, from the mouth of the Arno to Bala, are generally low and marshy. The Neapolitan coast along the Tyrrhenian and Ionian Seas,

up to Cape Rizzuto, is generally bold and rocky. Beyond Taranto, as far as Ancona, the shore is flat and sandy, being only broken by the spur on which stand Mts. Gargano and Sant' Angelo. Thence, northward to Rimini, the coast rises gradually, to subside rapidly beyond that city into a series of sandy islands, lagoons, and pestilential marshes, extending almost to the mouth of the Isonzo. All the rivers of *I.* are subject to sudden and very heavy floods, and, with the exception of the Po, the Adige, and the Tiber, have their volume of water greatly reduced in summer. The insignificant amount of tide in the Mediterranean renders most of them useless for navigation. In a country extending through 10 degrees of latitude there must be great difference of climate, and consequently of vegetation and agriculture, from position alone. Besides that, however, the climate of *I.* is greatly modified by the ranges of the Alps and Apennines, and by the air of the sea along its coast. In the plains of Piedmont and Lombardy, which are enclosed by mountains on every side but the E., the thermometer in winter descends to 10° F. Delicate plants do not thrive, except in sheltered situations, but the mulberry-trees flourish, rice is grown, and the pastures are rich. South of the Apennines, that part of Tuscany and former States of the Church which is near their main range is subject to great cold; but westward, and along the Riviera, the temperature grows milder, snow seldom lies long on the fields, and the climate is suitable to the growth of the olive and the orange. But it is when we reach the central range of the Apennines that we find the coldest districts of *I.* In all the upland valleys of the Abruzzi and of Saunio, snow begins to fall early in November, and heavy storms occur often as late as May. The district extending from the S. E. of Lake Fucinus to the Piano di Cinquesciglia, and enclosing the upper basin of the Sangro and the small lake of Scanno, is the coldest and the most bleak part of *I.* south of the Alps. Yet, less than 40 m. E. of this district we find the olive, the fig-tree, and the orange thriving luxuriantly on the shores of the Adriatic from Ortano to Vasto. In the same way, while in the plains and hills round Naples snow is rarely seen, and never remains long, and the thermometer seldom descends to the freezing-point, 20 m. E. from it, in the fertile valley of Avellino, of no great elevation, but encircled by high mountains, light frosts are not uncommon as late as June. But nowhere are these contrasts so striking as in Calabria. The shores, especially on the Tyrrhenian Sea, present almost a continued grove of olive, orange, lemon, and citron trees, which attain a size unknown in the North of Italy. The sugar-cane flourishes, the cotton-plant ripens to perfection, the date-trees are seen in the gardens, the rocks are clothed with the prickly pear or Indian fig, the enclosures of the fields are formed by aloes and sometimes pomegranates, the licorice-root grows wild, and the mastic, the rosemary, the myrtle, and many varieties of oleander and cistus form the underwood of the natural forests of arbutus and evergreen oak. If we turn inland but five or six miles from the shore, and often even less, the scene changes. High districts covered with oaks and chestnuts succeed to this almost tropical vegetation; a little higher up, and we reach the elevated table-lands of the Pollino and the Sila, covered with firs and pines, and affording rich pastures even in the midst of summer, when heavy dews and light frosts succeed each other in July and August, and snow begins to appear at the end of September or early in October.

**Agricultural Products.** The cerealia form, as elsewhere in Europe, the chief aliment of the inhabitants; in Italy, however, the lower classes, who are the most numerous, subsist much on maize and beans, which require little preparation to render them fit for food. In some of the southern parts wheat is made use of by the same class, both in the form of bread and in that of macaroni, which is manipulated with great facility. Wheat and maize are, on the average of years, about equal to the consumption, but little can be spared for exportation; and in many of the ports are depots of foreign wheat kept to meet the variations of seasons, or to be used as articles of commerce with other countries. Barley, oats, and rice are not extensively cultivated, but abundance of beans of various kinds are produced. Rice grows in many parts, in fact wherever there is a sufficiency of water to insure a good produce, at such distance from towns as not to be injurious to the health of the inhabitants. It is a part of almost every meal in families in easy circumstances, but is scarcely used by families who are in circumstances that require the practice of great parsimony. A great variety of lupines are used as food, especially in the soups. In some parts of the mountainous regions chestnuts are a substitute for corn as long as they last. Fruits are plentifully used, particularly figs, grapes, and melons, as food, while the cheapness of onions, garlic, tomatoes, and capiscum, render them valuable as condiments. The potato has been, but partially introduced into Italy; and, where it is cultivated, it occupies a very small proportion of the soil. Lettuce, asparagus, endive, artichokes, and several kinds of turnips and of carrots are everywhere grown. Animal food is far from being extensively used. The oxen yield in some parts excellent, in other very indifferent, meat. The mutton is neither good nor abundant, but has been much improved of late years. Swine furnish a plentiful supply during the winter months; they are also prepared as bacon or hams, and above all as sausages, the

fame of which latter has reached unto this country under the name of the city of Bologna, where they were early and extensively prepared. The large dairy farms in Lombardy, in which the cheese known by the name of Parmesan is made, and the oak and chestnut forests of Calabria, furnish the most and best swine's flesh. The sugar-cane is not cultivated in the South of Italy, as it is found that in point of strength, as well as of cost, the sugar made from it does not succeed in a competition with that substance when imported from the West Indies. The products of agriculture are sufficient for the clothing of all the inhabitants; for though wool is neither good nor plentiful, yet hemp and flax are grown everywhere, are manufactured at home, and, from the nature of the climate, linen can be substituted for woollen dress during most of the months of the year. Some raw wool is, however, imported to supply the manufactures, and some cloths, from England, France, and Bohemia. Cotton is grown extensively in the S. dis-

tricts of *I.*, but not sufficient to furnish materials for their manufactures of that article. The chief product of Italian agriculture is the silk. It is produced from every part, and much of it is converted into articles of dress or of furniture where it is collected; but the chief production of it is in Sardinia, Naples, and Lombardy. The value of this commodity exceeds that of all the other productions of *I.*, which are exported to foreign countries. The silk manufactures of *I.* are the most important in Europe, and are one of the great sources of national wealth: the number of spindles employed in silk spinning is about 3,000,000. Another very important Italian product, which is used partly as food, partly employed in home manufactures, and extensively exported as an article of foreign commerce, is the oil of the olive-tree. It is used as a substitute for butter in the S., is much appropriated to the manufacture of many kinds of soap, and is largely exported. The planting and watching cost but little labor or expense, and in a few years

the income more than recompenses the labor. The best olive-oil is produced near Genoa, in Lucra, in Tuscany, and in Calabria; but it is plentiful throughout the whole of *I.*, except in Lombardy and in Piedmont.

*Minerals.* Piedmont is especially rich in metals. In the Col di Tenda are mines of lead and silver. The Val d' Anzasca is renowned for its auriferous pyrites, the Val di Macagnaga for its beds of auriferous schists, and the Val d' Aosta for copper pyrites. In the serpentine rocks bordering the Gulf of Genoa are rich ores of copper; while the mountains of Modena are filled to their very summits with ores of iron, lead, and silver, and most valuable deposits of copper. The Apuan Alps, adjacent to the Modena chain, and forming the N. frontier of Tuscany, are traversed by veins of quicksilver, magnetic iron ore, and argentiferous copper and lead ores. The central and S. districts of Tuscany are equally favored with metalliferous deposits, among which the mines of Terricio and Castellina in

Fig. 292. — ARCH OF SEPTIMIUS SEVERUS (ROME).

tricts of *I.*, but not sufficient to furnish materials for their manufactures of that article. The chief product of Italian agriculture is the silk. It is produced from every part, and much of it is converted into articles of dress or of furniture where it is collected; but the chief production of it is in Sardinia, Naples, and Lombardy. The value of this commodity exceeds that of all the other productions of *I.*, which are exported to foreign countries. The silk manufactures of *I.* are the most important in Europe, and are one of the great sources of national wealth: the number of spindles employed in silk spinning is about 3,000,000. Another very important Italian product, which is used partly as food, partly employed in home manufactures, and extensively exported as an article of foreign commerce, is the oil of the olive-tree. It is used as a substitute for butter in the S., is much appropriated to the manufacture of many kinds of soap, and is largely exported. The planting and watching cost but little labor or expense, and in a few years

the centre, and those of Monte Catini near Volterra, deserve special mention. Further off are the mines of Campiglia, from which the Etruscans drew the greater part of their bronze. During the Middle Ages also various mines of iron, lead, copper, silver, alum, and sulphur were worked with great success in Massa Maritima, hence called Massa Metallifera to distinguish it from Massa Carrara. All over the face of the country, now covered with marsh and ravaged by fever, ancient pits, now ruins of old foundries are counted by the hundred. This same region, in the districts between Massa and Monte Catini, contains the famous *soffioni*, or vapor vents, utilized for the extraction of boracic acid. The districts of Siena and Grosseto also have silver and copper mines; and in S. Tuscany, besides these, are veins of quicksilver at Selvia, Pian Castagnajo, and Castellazzo, and lodes of antimony at Montano and Pereta. All these districts are on the W. flank of the Apennines. The former States of the Church are poor in metallic deposits; but

the Calabrias possess iron lodes and ancient silver-mines. The most important product of the Italian mines is sulphur, which is found in the island of Sicily and exported in large quantities. In many places there are excellent marble quarries, the best near Verona and Carrara. Alabaster and asbestos are found in many of the mountains. The salt manufactured on the seashore and from saline springs is largely exported.

*Commerce.* The commerce and industry are rapidly progressing since the unification of *I.* into a kingdom. The principal manufactures are silk, woollen, linen, and cotton goods, lace, straw hats, leather, pottery, and glass. Chemicals are largely manufactured, as also paper. The imports chiefly consist of sugar, coffee, and other colonial produce, muslios, calicoes, linens, woollens, hardware, and dyestuffs. The chief exports are raw and manufactured silks, rice, fish, fruit, sulphur, marble, velvet, mosaics, etc. The following table of imports and exports for the years 1876 and 1877 shows the relative importance of the commercial intercourse of *I.* with the different countries:—

Countries.	Imports, 1876.	Imports, 1877.	Exports, 1876.	Exports, 1877.
	Lire.	Lire.	Lire.	Lire.
France.....	428,200,000	332,100,000	547,300,000	418,900,000

5. Precious metals.....	14,000,000	19,000,000
Total.....	1,154,000,000	967,000,000

The commercial intercourse of *I.* with the U. States for the 10 years from 1839 to 1878 was as follows:—

Years.	Imports from the U. States.		Exports to the U. States.	Total Imports and Exports.
	Domestic.	Foreign.		
	\$	\$	\$	\$
1869....	5,682,951	23,224	6,209,863	11,916,038
1870....	6,344,912	129,741	6,641,664	13,116,317
1871....	6,090,449	68,776	7,443,754	13,602,979
1872....	5,438,718	13,468	7,592,191	13,044,377
1873....	7,241,097	54,552	7,974,542	15,270,191
1874....	8,378,666	4,019	8,499,294	16,881,979
1875....	7,226,564	1,516	9,190,182	16,418,251
1876....	7,770,470	17,005	7,628,772	15,416,247
1877....	8,484,496	10,172	7,105,366	15,600,034
1878....	8,786,719	4,381	6,711,006	15,462,106

The value of the principal articles imported from and exported to the U. States was as follows:—

— Imports: Indian corn, \$838,096; wheat, \$40,040; coal, \$9,676; raw cotton (18,110,597 lbs.), \$1,934,212; drugs, etc., \$15,085; naval stores, \$57,034; mineral oil, \$2,368,549; cotton-seed oil, \$778,042; lard, \$9,875; pork, \$9,326; spirits from grain (\$2,042 gals.), \$29,684; tallow, \$98,102; tobacco (leaf), \$2,239,948. — Exports: Argois, \$28,839; chemicals, etc., \$608,356; essential oils, \$203,968; sulphur, \$1,161,367; fancy goods, \$8,764; fruits and nuts of all kinds, \$2,769,045; kid gloves, \$11,086; marble, \$898,205; olive-oil, \$94,965; paintings, etc., \$62,671; salt, \$56,381; straw (manuf. of), \$107,994; wine, \$40,047.

To carry the above trade, 64 American vessels (tonnage 32,333) entered, and 76 (tonnage 37,833) cleared the Italian ports; 198 Italian vessels (tonnage 94,526) entered, and 453 (tonnage 464,450) cleared the American ports.

*Finances.* Since the establishment of the kingdom in 1861 the finances have been in an unsatisfactory condition. In every year, down to 1878, when for the first time the budget estimates left a surplus of 12,900,699 lire, the expenditures have considerably exceeded the revenue, necessitating large loans, foreign and internal, in consequence of which the public debt of *I.*, which stood at 2,439 millions of lire, or \$487,400,000, in 1860, the year before the establishment of the kingdom, had increased to 9,750 millions of lire, or \$1,950,000,000 in 1878. The debt was made up of the following liabilities:—

Liabilities.	Lire.
Funded debt inscribed in the "Libro Grande".....	7,091,829,661
Redeemable debt in the "Rentes" of 8 and 5 per cent.....	1,642,773,107
Treasury bonds.....	183,010,500
Paper currency.....	840,000,000
Total.....	9,757,613,267
	\$1,950,000,000

As a guaranty for the issued treasury bonds and of paper currency, which has a forced circulation, the government has deposits of certificates of the funded debt, bearing no interest, in the National Bank of *I.* The total amount of these deposits was calculated at 1,150,000,000 lire, or \$230,000,000, in 1878. Nearly all the cities and communes of *I.* have their own budgets and debts, the latter, like the national liabilities, tending to constant increase. The total revenue of the communes of *I.* in 1878 amounted, according to official reports, to 466,000,000 lire, or \$93,200,000, exclusive of those of the provinces of Rome. The amount was 316,800,000 lire, or \$63,360,000, in 1867, the first year in which Venice appeared as in *I.* There was thus an increase of 149,300,000 lire, or \$29,860,000, in the revenue during the ten years. The burden of the revenue per head of the population rose during the time in question from 12 lire, or 10s., to 18 lire, or 15s. In the urban communes—that is, in towns containing over 5,000 inhabitants—and the chief towns of provinces, the burden per head of the population was 34 lire, or £1 8s., against 10 lire 80c., or 8s 6d., in the rural communes. The burden per head of the urban population of *I.* was in 1878, in the province of Rome, 71 lire 62c., or \$14.32, and of the rural population of the kingdom, 19 lire 26c., or \$3.85.

*Shipping.* The number and tonnage of merchant vessels belonging to the kingdom, on January 1, 1879, were as follows:—

Tonnage of Vessels.	Sailing vessels.		Steamers.	
	No.	Tons.	No.	Tons.
From 801 to 1,000 tons....	8	7,145	.....	.....
" 501 to 800 ".....	172	100,216	9	4,893
" 301 to 500 ".....	591	363,648	34	11,608
" 101 to 300 ".....	1,357	252,852	31	6,212
" 21 to 100 ".....	3,011	140,786	.....	.....
" 6 to 20 ".....	3,493	41,962	.....	.....
Under 6 tons.....	9,214	24,775	36	2,427
<b>Total.....</b>	<b>17,846</b>	<b>933,184</b>	<b>110</b>	<b>25,140</b>

**Railroads.** The total length of lines open for traffic at the beginning of 1879 was 8,210 chilometri, or 5,131 miles, of which 2,126 chilometri, or 2,049 miles, belonged to the State, and 6,084 chilometri, or 3,082 miles, to private companies. The whole of the lines are divided into five systems, of the following extent:—

RAILROADS.	Length.	
	Chilome- tri.	Miles.
<b>Alta Italia.....</b>	<b>3,379</b>	<b>2,112</b>
Roman (Rome).....	1,073	1,045
Southern (Meridional).....	1,454	908
Sardinian (Sardeg.).....	198	124
Sicilian (Calabro-Sicula).....	949	593
Various lines.....	557	349
<b>Total.....</b>	<b>8,210</b>	<b>5,131</b>

The first line of railroad was open in 1839, and the progress of construction was slow till 1861, from the beginning of which year till the end of 1866 the length opened for traffic rose to 2,902 chilometri, or 1,814 miles. In the following six years, till the end of 1872, the length opened for traffic was 1,963 chilometri, or 1,039 miles, and in the next three years, till the end of 1875, it was 932 chilometri, or 583 miles. The construction of railroads by the State was begun in recent years, in order to extend, more rapidly than private enterprise was willing to do, the existing network of lines. In October, 1875, the government purchased from the South-Austrian and Lombardo-Venetian Railroad Company the Italian portion of the system, or the "Alta Italia" lines, of a length of 1,444 chilometri, or 915 miles. In the session of 1878 the Italian Parliament passed a bill for the construction of an additional 4,000 chilometri, or 2,500 miles, of railroad, to complete the existing system. The new lines are to be built within a period of 15 years, at a total cost of \$30,000,000 lire, or \$170,000,000, with a State contribution of 650,000,000 lire, or \$120,000,000, paid in annual instalments of 50,000,000 lire, or \$10,000,000.

**Money, Weights, and Measures.** The money, weights, and measures of *I.* are the same as those of France, the names only being altered, the Franco changing into the Lira, divided into 100 Centesimi, the Kilogramme into the Chilogramma, the Mètre into the Metro, the Hectare into the Ettara, and so on. The American equivalents are:—

#### MONEY.

The *Lira*, of 100 *Centesimi* = Average rate of exchange, \$0.193.

#### WEIGHTS AND MEASURES.

The <i>Gramma</i> .....	=	15.434 grains troy.
" <i>Chilogramma</i> .....	=	2.20 lbs. avoirdupois.
" <i>Quintal Metrici</i> .....	=	220 " "
" <i>Tonnelata</i> .....	=	2200 " "
" <i>Litro</i> , Liquid Measure =	0.22	gallon.
" <i>Ettolitro</i> { Liquid Meas. =	22	" "
" { Dry Measure =	2.75	bushels.
" <i>Metro</i> .....	=	3.28 feet, or 39.37 inches.
" <i>Chilometro</i> .....	=	1093 yards.
" <i>Metro Cube</i> {.....	=	35.31 cubic feet.
" <i>Stero</i> .....	=	2.47 acres.
" <i>Ettara</i> , or <i>Hectare</i> .....	=	2.47 acres.
" <i>Stero Chilo</i> , or <i>Kilo- mètre Carré</i> .....	=	0.386 square mile.
	(2.59	sq. chilo = 1 sq. mile.)

The common currency of the kingdom in recent years has been paper money of various denominations, gold standing at a premium of from 12 to 18 per cent.

**Seaports.** The principal harbors of *I.* are: on the W., Genoa, Gallipoli, Chiavari, Spezia, Leghorn, Civita Vecchia, Gaeta, Naples, and Reggio; on the S., Taranto; on the E., Brindisi, Bari, Ancona, Rimini, Chioggia, and Venice. Among these

ports, a special notice is given below to those which have some connection with American trade. The ports of Messina and Palermo are given under SICILY, and Cagliari under SARDINIA.

**Chiavari**, a maritime town of the province of Genoa, 21 m. E. S. E. of the city of that name, on the Gulf of Rapallo, at the mouth of the Sturia. The best Italian anchovies are fished here, and largely exported. Pop. 15,000.

**Civita Vecchia**, a seaport town of the Roman territory, in lat. 42° 4' 38" N., lon. 11° 44' 52" E. It is the best and almost the only port on the coast of the former States of the Church, and is about 24 m. to the W. of Rome. The port enjoyed under the Popes commercial freedom and sundry special privileges. But its commerce declined in recent times almost to zero. Pop. 9,000.

**Gaeta**, a fortified seaport town of S. Italy, prov. Caserta, at the end of a peninsula on the W. shore of the kingdom, forming the N. W. boundary of the gulf to which it gives its name; 4 m. S. S. W. of Mola di Gaeta, 41 N. W. of Naples, and 72 S. E. of Rome. The town is regarded as one of the keys of S. Italy, being strong from its natural position, which art has taken advantage of. Its port, which has 7 fathoms water, though not the largest, is one of the safest and best in Italy. *G.*, situated in a beautiful tract of country, is the centre of a considerable trade. Pop. 20,000.

**Gallipoli**, a fortified seaport town of S. Italy, prov. Lecce, on a rocky islet on the E. coast of the Gulf of Taranto, 40 m. S. E. of Taranto, and 28 W. S. W. of Otranto. *G.* is connected by a bridge with the main-land, on which is its suburb Lizza. *G.* displays an air of great industry, if not of affluence, and is the most frequented of all the ports on the S. E. coast of Naples, being the great mart for the oil of Apulia, most of which is shipped here. Many of the inhabitants are engaged in the tunny fisheries. Pop. 10,000.

**Genoa**, a maritime city of *I.*, once the capital of the famous republic of that name. It is situated at the bottom of the extensive gulf to which it gives its name; the light-house being in lat. 44° 24' 18" N., lon. 8° 54' 24" E. Genoa is one of the finest and most interesting cities of Europe. Being built on a rising ground, in the form of an amphitheatre, with the bare summits of the Apennines and the ice-covered peaks of the Alps behind, the appearance of the city from the sea is most magnificent, and justifies the old epithet given to her of *la Superba*. The harbor is semicircular, the diameter being about 1,000 fathoms. It is artificial, being formed by 2 gigantic moles, having opposite directions. That on the E. side, called the old mole (*molo vecchio*), projects from the centre of the city W. by S. It is about 260 fathoms in length. The new mole (*molo nuovo*), on the opposite side of the port, adjoins the S. extremity of the suburb of St. Pietro d'Arena, projecting about 210 fathoms from the shore in an E. S. E. direction. The heads of the moles bear from each other N. E. by E. and S. W. by W., the distance between them, forming the entrance to the harbor, being about 350 fathoms. The light-house is without the port, on the W. side, near the extremity of a point of land, and contiguous to the bottom of the new mole. It is a lofty square tower, and as it stands on a high rock, and is painted white, it is visible in clear weather at a great distance. There is no difficulty in entering the harbor; the ground is clean, and there is plenty of water, particularly on the side next the new mole: care, however, must be taken, in coming from the W., to give the light-house point a good offing. Moderate-sized merchantmen commonly anchor inside the old mole, contiguous to the *porta franca*, or bonded warehouses, having a hawser made fast to the mole, and an anchor ahead. Men-of-war and the largest class of merchantmen may anchor inside the new mole, but they must not come too near the shore. Ships sometimes anchor without the harbor in from 10 to 25 fathoms, the light-house bearing N. J. W.; distance 2 or 3 m. The S. W. winds occasion a heavy swell, but the bottom is clay, and holds well. Within the town are 2 rather shallow basins designed for galleys and small trading vessels. There is also an arsenal. Genoa is the entrepôt of a large extent of country; and its commerce, though inferior to what it once was, is very considerable, and has latterly been increasing. It is a free port; that is, a port where goods may be warehoused and exported free of duty. The exports consist partly of the raw products of the adjacent country, such as olive-oil, rice, vermicelli, hemp, rags, argol, etc.; partly of the products of her manufacturing industry, such as silks, damasks, and velvets (for the production of which she has long been famous), thrown silk, paper, soap, works in marble, alabaster, coral, etc.; the printed cottons of Switzerland, and the other products of that country and of the western parts of Lombardy, intended for the S. of Europe and the Levant; and partly of the various foreign products brought by sea and placed in *porta franca*. The imports principally consist of cotton, cotton stuffs and yarn, iron and hardware, linens and woollens, machinery, copper, coals, etc.; cotton-wool, mostly from the U. States and Egypt; corn from the Black Sea, Sicily, Barbary, and the U. States; sugar, spices, coffee, cochineal, and indigo; hides; naval stores from the Baltic; codfish, wool, tobacco, lead (principally from Spain), wax, etc. Corn, barilla, Gallipoli oil, cotton, valonia, sponge, galls, and other products of the countries adjoining the Black Sea, Sicily, the Levant, etc., may in general be had here, though not in so great abundance as at

**Leghorn** Numerous lines of steamers ply between Genoa and Leghorn, Civita Vecchia, Spezia, Naples, Messina, Tunis, Nice, Marseilles, etc.

The *Bank of Genoa*, or of St. George, was one of the most ancient and celebrated banks of circulation and deposit in Europe. Until 1746, when the bank was pillaged by the Austrians, it was customary to make all bills of exchange drawn upon Genoa payable in *banco*, but since then they have generally been made payable in money *fuori di banco*. In 1800, when the French were besieged in Genoa by the Austrians, they took the treasure of the bank to pay their troops. The establishment has never recovered from this blow; some warehouses and a part of the town's revenue were assigned to it, but they yield a very poor dividend. It is no longer used as a place of deposit for money. In 1844 a new bank was established in Genoa, which being united in 1855 to a bank that had been established at Turin in 1847, has the title of National Bank (*Banca Nazionale*). Its capital amounts to 32,000,000 lire, in shares of 1,000 lire each. It is authorized to issue notes of the value of 1,000, 500, 250, 100, 40, 25, 10, and 5 lire. The amount of its notes in circulation and debts payable on demand were, down to 1893, limited to 3 times the amount of the coin in its coffers. But the crisis of that year led unfortunately to the introduction of an inconvertible paper currency. The bank discounts mercantile paper, and transacts all kinds of ordinary banking business. It has branches at Turin and other places.

**Leghorn** [It. *Livorno*], a city and seaport of the province of Tuscany, in lat.  $43^{\circ} 33' 5''$  N., lon.  $10^{\circ} 16' 45''$  E. Leghorn has an outer harbor, protected by a fœe mole, running in a N. N. W. direction upwards of  $\frac{1}{2}$  m. into the sea, and a small inner harbor, or basin. The water in the harbor is rather shallow, varying from 8 feet in the inner basin to 18 or 19 feet at the end of the mole. The rise of the tide is about 14 inches. Ships lie within the mole with their sterns made fast to it by a cable, and an anchor out ahead. The light-house is built on a rock a little to the S. W. of the mole. It is a conspicuous object, being about 170 feet above the level of the sea. The roadstead lies W. N. W. of the harbor, between it and the Melora bank. The latter is of sand, lying N. and S., 4 m. in length by 2 in breadth, the side nearest the shore being about  $\frac{1}{2}$  m. from it. It consists, for the most part, of sand and mud, and has from 3 fathoms to  $\frac{1}{2}$  fm. water over it; but towards its S. extremity it is rocky; and there, on some of the points which project above the water, the Melora tower has been constructed to serve as a sea-mark; it bears from the light-house W.  $\frac{1}{2}$  N., distant about 4 m. The best course for entering the roads is to keep to the northward of the Melora bank at about 1 m. from it, and then, having doubled it, to stand on for the light-house about  $2\frac{1}{2}$  m., anchoring in from 7 to 9 fathoms, the light-house bearing S. S. E.  $\frac{1}{2}$  E., 4 m. off. During southerly winds there is sometimes a heavy sea in the roads, but the holding ground is good; and with sufficient anchors and cables, and ordinary precaution, there is no danger. The Lazaretto lies to the S., about 1 m. from the tower, and is said to be one of the best in Europe. The comparative security and freedom which foreigners have long enjoyed in Tuscany, still more than its advantageous situation, render Leghorn the greatest commercial city of *I.* Its exports are similar to those from Genoa. Leghorn plaiting for straw hats is the finest in the world; and large quantities are imported into the U. States. Besides the above, all sorts of articles, the produce of the Levant, may be had at Leghorn. The imports are exceedingly numerous and valuable, comprising all sorts of commodities, with the exception of those produced by Italy. Ships with corn on board may unload within the limits of the Lazaretto, without being detained to perform quarantine,—a circumstance which has contributed to make Leghorn one of the principal depots for the wheat of the Black Sea. Hard wheat, particularly from Taganrog, is in high estimation here and in the other Italian ports. It is particularly well fitted for making vermicelli, macaroni, etc.

In 1833 a joint-stock bank was established in Leghorn, with a capital of 2,000,000 lire, in shares of 1,000 lire each. The whole of the capital is paid up, and the responsibility is limited to the capital. The managers have the power of issuing promissory notes to the extent of 6,000,000 lire. These notes, though received by the government, are not legal tender. The operations of the bank are confined to the discounting bills of exchange not having more than 4 months to run, and to the purchase and sale of foreign coins. The superintendence is vested in a director and 8 regents, nominated by the shareholders; and the government appoints a commissary and 3 censors (from among the shareholders), who exercise the highest authority, to secure obedience to the statutes. An annual report and balance-sheet is produced, and is accessible to all shareholders. It is a profitable establishment, and its shares are at a considerable premium.

**Naples**, a large city and seaport in the S. of *I.*, in Campania, and formerly the capital of the kingdom of the same name, on the N. side of the Bay of Naples, 118 m. S. E. of Rome, near the foot of Mt. Vesuvius; lat.  $40^{\circ} 51'$  N., lon.  $14^{\circ} 15'$  E. The situation of Naples is one of the most delightful that can be imagined. In the form of an amphitheatre, it is built partly on the declivity of a hill, partly on the margin

of a spacious bay, spreading its population along the shore, and covering the shelving coasts and adjacent enclaves with its villas and gardens. The bay is extensive, and presents an almost unrivalled assemblage of picturesque and beautiful scenery. The entrance of the bay, from Cape Miceno on the N. W. to Cape Campanella on the S. E., has a width of about 20 m., with a circuit of about 35 m., and an indentation of about 15 m. It is well sheltered, and has good anchorage, with 7 fathoms of water. At the N. W. entrance are the islands of Ischia and Procida, and at the S. E. the island of Capri. Naples has 3 ports: the Porto Piccolo (the ancient port of Paestopolis), now only suited to small craft; the Porto Militare, a new harbor with a depth of water of 5 fathoms, bounded S. by

FIG. 293. — PEASANT OF THE CAMPAGNA.

a mole which runs in a S. E. direction into the sea for a distance of 1,200 ft.: and the Porto Grande, the principal port, but with only 3 or 4 fathoms in its deepest part, having suffered from the silting of the sand and shingle. The most important manufacture is of macaroni and vermicelli, which constitute the principal food of the people. Next in importance is the production of silk goods, the Gros de Naples taking its name from the manufacture of this city. There are also iron and glass works, manufactories of carpets, broadcloth, chemical soaps, perfumery, artificial flowers, corals, porcelain, hats, carriages, gloves, etc. The exports principally consist of the products of the adjacent country. Of these, silk and olive-oil are the most important. The other articles of export are wool, wine, brandy, dried fruits, red and white argol, tallow, licorice, lamb and kid skins, oak and chestnut staves, rags, saffron, etc. The chief imports are sugar, coffee, spices, coal, salted fish, cotton, woollen, silk, and flax goods; iron, tinware, and hardware. — The principal merchants of Naples are all, more or less, bankers inasmuch as they advance money on letters of credit, and deal in foreign exchanges, and other financial operations, which are too often carried on in a

reckless manner. There are, however, several great banking establishments which are perfectly secure. — Goods are universally sold at long credits, mostly from 4 to 8 months; and for manufactured goods, sometimes longer. On sales of indigo, from 12 to 18 months' credit is given. Discount for ready money is at the rate of 6 per cent per annum. Merchants are arranged by the Chamber of Commerce into 5 different classes; and a 6 months' credit is given to individuals at the custom-house for duties according to the class in which they happen to be enrolled. But this is of little importance. Unless the transactions of a merchant be very limited indeed, the duties he has to pay amount to much more than the credit he is allowed.

**Venice**, a famous city and seaport of *I.*, formerly the capital of the republic of that name, and previous to 1866 belonging to the Austrian Empire, on a cluster of small islands in the northern extremity of the Adriatic, now joined to the mainland by a railroad bridge, part of the line to Padua, in lat. 45° 25' 53" N., lon. 12° 20' 31" E. The islands on which Venice is built lie within a line of long, low, narrow islands, running N. and S., and enclosing what is termed the lagoon, or shallows, that surround the city, and separate it from the mainland. The principal entrance from the sea to the lagoon is at Malamocco, about 1½ leagues S. from the city; but there are other, though less frequented entrances, both to the S. and N. of this one. There is a bar outside Malamocco, on which there are not more than 10 feet at high water at spring tides; but there is a channel between the W. point of the bar and the village of San Pietro, which has 16 feet water at springs, and 14 at neaps. Merchant vessels usually moor off the ducal palace; but sometimes they come into the grand canal which intersects the city, and sometimes they moor in the wider channel of the Giudecca. On arriving at the bar ships are conducted across it and into port by pilots, whose duty it is to meet them outside, or on the bar, and of whose services they must avail themselves. — The commerce of Venice, once the most extensive of any European city, is now comparatively trifling, and it is perhaps the only commercial city whose population has not increased since the unification of *I.*

In 1830 Venice was made a free port, and down to 1866, when she became part of the kingdom of *I.*, fully participated in every privilege conferred on Trieste. But, notwithstanding this circumstance, the latter continued to preserve the ascendancy; and the revival of trade that has taken place at Venice has not been so great as might have been anticipated. The truth is, that except in so far as she is the entrepôt of the adjoining provinces of Lombardy, Venice has no considerable natural advantage as a trading city; and her extraordinary prosperity during the Middle Ages is more to be ascribed to the comparative security enjoyed by the inhabitants, and to their success in engrossing the principal share of the commerce of the Levant, than to any other circumstance. Still, however, her trade is far from inconsiderable. Venice has always been celebrated for its glass pearls, beads, and other glass wares, made in the city and on the island of Murano. The ancient manufacture of brocade tapestry has recently been revived, and also that of the lace-work for which the adjacent island of Burano was always celebrated; and a new feature of industry is the imitation of ancient furniture, made of pear-wood and bone instead of the ebony and ivory formerly used. The great articles of import are sugar, coffee, tobacco, and other colonial products, indigo and other dyestuffs, olive-oil, oil-seed, coal, iron, salted fish, various descriptions of cotton, woolen, and other manufactured goods, wheat and other grain, tin plates and hardware, raw cotton, etc. Venice is the principal market of the petroleum trade with the U. States. The exports principally consist of silk and silk goods, wheat and other grain, piper, jewelry, glass, and glass wares, Venetian trawls, books, with a great variety of other articles, including portions of most of those that are imported.

**Item**, a memorandum; a new article; one of the particulars of an account.

**Ithaca, Auburn, and Western R.R.** runs from Freeville, N. Y., to Scipio, N. Y., 27 m. This Co., whose offices are in New York City, has succeeded the Western Extension of the New York and Oswego Midland R.R., which was sold under foreclosure. The road is now operated as a branch of the Utica, Ithaca, and Elmira R.R. *Financial statement:* Cap. stock, \$970,000; funded debt, \$514,650, as follows: 1st mortgage bonds, issued 1876, \$16,500, payable 1906, interest 7% (June and Dec.); 2d mortgage bonds (income for 3 years), issued 1877, \$498,090, payable 1907, interest 7% (July and Jan.).

**Itinerant**, a wanderer; a pedler; a workman who travels from place to place.

**Itinerary**, a distance-guide, etc., for travellers; an account or description of a country.

**Ivory**, the commercial name for the bony matter of the tusks of the elephant, the teeth of the hippopotamus and walrus, the horn of the narwhal, etc. Elephant *I.* is the most esteemed, and that obtained in the largest quantity. The tusks of elephants are hollow at the root, tapering, and of various sizes, depending principally on the age of the animal. Color externally, yellowish, brownish, and sometimes dark; internally, white. The best are large, straight, and light-colored, without flaws; not very hollow in the stump, but solid and thick. The most esteemed come from Africa, being of a closer texture, and less liable to turn yellow, than those from the East Indies. In trade, they are usually thus divided: First sort, weighing 70 lbs. or upward; second sort, weighing 50 lbs. to 60 lbs.; third sort, weighing 38 lbs. to 50 lbs.; fourth sort, weighing 28 lbs. to 37 lbs.; fifth sort, weighing 18 lbs. to 27 lbs. All under 18 lbs. are called *sericillos*, and are of the least value. In purchasing elephants' teeth, those that are very crooked, hollow, and broken at the ends, or cracked and decayed in the inside, should be rejected; and care taken that lead or any other substance has not been poured into the hollow. The western and eastern coasts of Africa, the Cape of Good Hope, Ceylon, India, and the countries to the eastward of the Straits of Malacca are the great marts whence supplies of *I.* are derived. The chief consumption of *I.* is in the manufacture of handles for knives; but it is also extensively used in the manufacture of musical and mathematical instruments, chess-men, billiard balls, plates for miniatures, toys, combs, etc. *I.* articles are said to be manufactured to a greater extent, and with better success, at Dieppe, than in any other place in Europe. But the preparation of this beautiful material is much better understood by the Chinese than by any other people. No European artist has hitherto succeeded in cutting concentric balls after the manner of the Chinese; and their boxes, chess-men, and other *I.* articles are all far superior to any that are to be met with anywhere else. The value of *I.* and *I.* goods imported into the U. States during the year 1878 was \$327,955.

*Imp. duty:* unmanufactured, free; bagatelle, billiard, and chess balls, chess-men, dice, and draughts, of *I.*, 50 per cent.; all other manuf. of *I.*, 35 per cent.

*Manuf.* In the working up of *I.* into handles, billiard balls, chess-men, organ and piano-forte keys, veneers, etc., much difficulty is experienced; for some of the tusks are more hollow than others, some more crooked, some more irregular in color and texture. The larger and straighter the tusk, the easier it is to work. Thin saws are used to cut up the tusk, and great tact is needed in arranging the cuts so that the valuable substance may be applied to the best advantage. Each variation in hardness, whiteness, etc., renders the *I.* useful for some purposes rather than others; and it is the *I.*-worker's business to determine all those matters as he goes on. He pencils the tusk, after closely examining it, and makes his saw-cuts along the pencil-marks. The turning, planing, polishing, carving, etc., of *I.*, depend on the same mechanical principles of hard wood; but the peculiarities and coarseness of the substance render great care necessary (see *VENER.*). *I.* is exquisitely smooth in working, altogether devoid of the harsh, meagre character of bone, and is in all respects the most suitable material for ornamental turning, as it is capable of receiving the most delicate lines and cutting. The artists of Greece and Rome carved from the tusks of the elephant beautiful statues, and *I.* was also a favorite material for sculpture in the Middle Ages. *I.* can be bleached, and also dyed, by various modes of treatment. To render it soft and transparent, small pieces of the article are laid in strong phosphoric acid, until they become transparent, then rinsed in water, and dried in pure linen. When dry it is dipped in warm water or milk. It softens as often as it is dipped with different pieces of *I.* The time of immersion in the acid differs with different pieces of *I.* If certain parts are to retain their original character, they are covered with a varnish before immersion. The acid probably acts by forming an acid phosphate of lime out of the boric phosphate which constitutes three fourths of *I.* The process

of hardening *I.* which has become pliable by age consists in boiling it for some time in a solution of gelatin. — Many substitutes for *I.* have been introduced. The best is celluloid (see CELLULOID), which for many purposes is often preferred to *I.* See also VEGETABLE IVORY.

**Ivory Black**, a kind of vegetable charcoal, prepared by calcining the shavings and dust of ivory. It is ground and levigated on a porphyry slab to produce the beautiful velvety material

which is the chief ingredient of the ink used in copperplate printing. The name is also frequently applied to bone-black. See CHARCOAL (ANIMAL).

**Ivory Fictile** is plaster of Paris which has been made to absorb a certain amount of melted spermaceti, or by mixing the plaster with yellow ochre. It is used for casts.

**Ivory Nut.** See VEGETABLE IVORY.
